WILLIAM WITHERING PROFESSOR OF MEDICINE,
UNIVERSITY OF BIRMINGHAM

OR the past decade or so clinicians have been approach- ; the problems of cardiac and renal failure along ysiological lines, thinking in terms of cardiac output, merular filtration-rates, and so on But they still m curiously reluctant to use physiological lines of ught in the analysis and treatment of respiratory ease We now have many comparatively simple and sonably accurate methods of measuring respiratory ction, and these greatly sharpen clinical diagnosis t many British teachers of medicine either ignore them gether or refer to them as some sort of activity of kroom playboys and not the sort of thing for a good ctical doctor The current clinical approach is still minated by " stony dullness " and " dry sounds " e position is much better in the United States, where a large number of centres adequate physiological estigation of respiratory disease is regarded as normal cedure The writers of the respiratory sections of erican textbooks base their presentation at least as ch on the physiological approach as on the purely rbid-anatomical

erhaps all this is due to the innate conservatism of the l World, but the fault is not solely that of the clinician s also that of the physiologist, because in some British dical schools the treatment of respiratory function is l frozen at the stage of " lung statics "

linically the concept of respiratory failure, while it long been obvious in such gross asphyxial conditions laryngeal obstruction, has had comparatively little ntion in the many other conditions which involve the gs Perhaps too much emphasis has been placed on effect of these conditions on cardiac function, and the ulting varied symptoms have been regarded as cardio- cular rather than respiratory in origin

Respiratory failure can be defined simply as that dition in which the amount of oxygen and carbon xide in the blood-stream is altered by an abnormality he respiratory system On the analogy of other systems can recognise a preliminary stage of " respiratory ufficiency " in which blood-gas levels, normal at rest, ome abnormal during exercise

An analysis of the mechanisms of respiratory failure ls naturally into the three zones of respiratory function

Ventilatory Zone

The ventilatory zone is concerned with the maintenance the alveolar gas tensions at such a level as will ensure it pulmonary capillary blood is saturated with oxygen fore it leaves the respiratory portion of the capillary d that it has rid itself of the necessary amount of carbon xide over the tension range 46–40 mm Hg This quires, on the purely mechanical side, appropriate nction of the bellows mechanism of the chest and a nfiguration of the airways, in respect of relative ameters, &c , which will ensure a uniform distribution of inspired air Furthermore the general texture of the lungs must be such that an excessive amount of work is not done in distending them The rate and depth of respiration are regulated by reflex arcs which sense the blood-oxygen tensions (from chemoreceptors principally in the carotid sinus) and the carbon dioxide and pH of the blood passing through the respiratory centre in the medulla Proprioceptive impulses from the lungs and chest wall also play a part in regulating depth and rate of respiration

A variety of physiological measurements are appropriate to the ventilatory zone Of these the most useful give some index of the amount of air that can be moved per unit of time

One of the simplest is the Wright peak expiratory flowmeter (P F M) † known more familiarly as the " huffer " This is an adaptation of the anemometer used in a meteorological station to indicate the velocity of wind The patient is merely asked to blow out as hard and as fast as he can through this instrument and a needle jumps up to the maximum velocity attained, which in normal adults is of the order of 500 litres per minute (Wright and McKerrow 1959)

There are many other ways of measuring the maximum breathing capacity (M B C), such as by having the patient breathe as hard as he can into a bag of the Douglas type with the mouthpiece arranged so that inspiration is from the external air The precise time of 12–15 such breaths is recorded. The volume is then measured in litres, converted to the equivalent volume at 37°C and 760 mm. Hg, and expressed as the volume per minute In normal adults it is of the order of 150 litres

A lot of useful information about ventilation can be obtained from a simple spirographic tracing, provided the drum can go fast enough to adequately display a single breath If the spirometer is of the type described by Bernstein et al (1952) it can be used for recording the maximum breathing capacity For this purpose the ordinary Benedict-Roth spirometer, which has been a feature of the clinical physiological laboratory for the past thirty years, is quite unsuitable because of the inertia of its moving parts and because its resonance frequency is about 0 5–1 cycle per second, which means that it overswings grossly when the subject breathes rapidly The expiratory flow-rate can be measured from the straight part of the downstroke of a spirogram of a forced expiration, provided the drum speed is fast enough to open up the time base

There is still a place—though not a very large one—for the measurement of the divisions of lung volume, such as vital capacity, inspiratory capacity, and expiratory reserve volume, and also for the measurement of functional residual capacity by the closed-circuit helium-dilution method (McMichael 1939) or the open-circuit nitrogen method (Darling, Cournand, and Richards 1944) From these data the total lung capacity can be calculated These measurements, although often distorted in disease, do not provide very specific help, because the changes are common to a wide variety of disorders

An important aspect of ventilation is the efficiency with which each inspiration is mixed with the pre-existing air in the lungs

Of the various ways of measuring this perhaps the cheapest is to arrange that the patient breathes pure oxygen for seven minutes, by which time a normal person should have reduced the nitrogen content of his expired air to less than 2 5% (Cournand et al 1941) Values of 15–20% are common in seriously impaired distribution

---

[*] The Frederick Price lecture given to the School of Physic, Trinity College, Dublin, on Nov 24, 1959

† Made by Airmed Ltd , 16, Wigmore Street, London, W 1

Undoubtedly the most convenient method at present available is the single-oxygen-breath procedure, in which, with the aid of a nitrogen meter, a record is made of the nitrogen content of the expiration immediately after a maximal inspiration of oxygen (Comroe and Fowler 1951) In the normal person, as soon as the dead-space gas consisting of pure oxygen is expired, the nitrogen content rapidly climbs to a plateau which is very nearly flat at any rate its slope is no more than equivalent to 1 5% of nitrogen increase from the 750 ml to the 1250 ml levels of expiration Defective distribution of air is indicated by replacement of the plateau by a gentle ascent terminating with gas which has so much nitrogen in it as to show that comparatively little of the maximum breath of oxygen has penetrated to that part of the lung

Diffusion Zone

Oxygen and carbon dioxide have to cross the thin layer of fluid and endothelium which separates alveolar gas and capillary blood Normally this is only about 2 μ thick The rate at which gas traverses this pathway is governed by the difference in tension at the two extremities, the length of the pathway, and the specific solubility and diffusibility of the gas concerned In this respect normal gaseous exchange requires the absorption of oxygen and the elimination of carbon dioxide at a resting volumetric equivalence sufficient to satisfy metabolic demands and to maintain a ratio between the two gases of approximately 5 4 This latter value is set by the overall respiratory quotient of the individual

Since carbon dioxide is much more diffusible (20 1) than oxygen, the normal tension difference of only 6 mm (46–40) between the carbon-dioxide tension of mixed venous blood and that of alveolar air is sufficient to ensure the elimination of an adequate amount In fact the carbon-dioxide tension of the alveolar air and of the arterial blood leaving the lungs is identical This is not true of oxygen, which is so much less diffusible that even at the comparatively high tension difference between 104 mm Hg in the alveoli and 40 mm Hg in mixed venous blood, hæmoglobin is barely saturated by the time it leaves the capillary Even in health, there is a small tension difference (9 mm) between the alveolar air and arterialised blood, although this is partly due to shunting

Estimation of the efficiency of diffusion is essentially by the study of blood-gas levels and their relation to alveolar tensions

The important measurement (Riley et al 1951) is the amount of oxygen passing across the membrane per millimetre difference of oxygen tension (diffusion capacity) Technically this is not a very easy measurement because it requires an arterial puncture so that the carbon-dioxide tension of the arterial blood can be measured This is regarded as identical with the carbon-dioxide tension of the alveolar air—from which, and from the exchange ratio, we can calculate the oxygen tension of the alveolar air The oxygen tension of the arterial blood is also measured, thus enabling the gradient between alveolus and capillary to be obtained

This is not, however, quite so straightforward as it looks, for part of the difference between alveolar and arterial oxygen tensions is due to the admixture of a certain amount of blood which has bypassed the alveoli or—what comes to the same thing—has passed through imperfectly ventilated alveoli Fortunately Riley et al (1951) with great ingenuity discovered that this admixture factor could be rendered negligible by making the measurements during inhalation of only 14% oxygen It is thus possible to measure the alveolar-capillary gradient due to membrane factor—i e , membrane thickness

There is, however, one desirable measurement which cannot yet be made directly in man and that is the area of the membrane A reduction of diffusion capacity by half could theoretically be due to a doubling of the mean thickness of the alveolar-capillary pathway or a halving of the area of the alveolar-capillary interface Fortunately, in practice, this is not usually a serious difficulty, because collateral evidence often indicates which of those two parameters is at fault For instance, when the patient has a collapsed lung or has had lung tissue removed, a reduction in diffusing capacity is obviously due to loss of area

There are other methods of measuring diffusing capacity—notably the carbon-monoxide-single-breath method, which, in outline, consists in measuring the amount of carbon monoxide absorbed from a single breath held for ten seconds (Krogh 1914–15, Bates and Christie 1950) The affinity of hæmoglobin for carbon monoxide is so high that for all practical purposes the carbon-monoxide tension of pulmonary capillary blood can be taken as zero Therefore the gradient is simply the mean carbon-monoxide tension of the alveolar air This method, however, does not provide for estimation of the admixture factor

The foregoing diffusion tests are admittedly beyond the scope of any but a specialist laboratory Fortunately a lot of useful clinical information can be obtained from the measurements of the blood tensions of oxygen and carbon dioxide

The normal person has an arterial-blood oxygen saturation of 95%, the difference between that and 100% being due chiefly to the normal amount of alveolar shunting Abnormal oxygen unsaturation of arterial blood, if severe enough, will lead to visible cyanosis, although it must be remembered that the shape of the curve relating the oxygen content of hæmoglobin to the oxygen tension is such that when cyanosis is actually visible the oxygen tension of arterial blood has dropped 40 or 50 mm Hg It is wise, if the patient is fit enough, to have him do some mild exercise while the arterial needle is in position, for in many conditions, whereas oxygen saturation is normal at rest, it falls markedly on exercise Now, in the absence of gross shunting, arterial unsaturation is due to one of two factors—either a ventilatory defect lowering alveolar oxygen tension (as in ventilatory insufficiency) or severe loss of diffusion capacity (as in alveolar-capillary block) If, however, at the same time the carbon-dioxide tension of the arterial blood be measured, then these two causes of unsaturation can be sharply differentiated If poor alveolar ventilation be the cause, then, just as the oxygen tension of alveolar air is too low, so will the carbon-dioxide tension be too high—because, as it must be eliminated, it will accumulate in the plasma until it attains the 6 mm ascendance over alveolar carbon-dioxide tension necessary for escape Therefore, anoxia plus hypercarbia means ventilatory insufficiency On the other hand, in alveolar-capillary block, carbon dioxide, owing to its high diffusibility, still diffuses out at normal tensions Indeed, the hyperventilation may actually wash carbon dioxide out of the blood-stream, leading to an abnormally low arterial tension

The differentiation between those two important types of respiratory defect has been simplified even further by the direct measurement of the alveolar carbon-dioxide tension As Plesch (1909) originally pointed out, and as Collier (1956) and Campbell and Howell (1958) have emphasised, the carbon-dioxide content of expired alveolar air is identical with that of mixed venous blood when the subject has rebreathed to equilibrium with a bag of air The addition of 6 mm to this value can be taken as a good indication of the carbon-dioxide tension of arterial blood A method very useful in routine clinical practice is to have the patient breathe in and out of a bag taining pure oxygen After a minute and a half this bag s a carbon-dioxide content very close to that of the tient's alveolar gas The bag is then laid aside for a few inutes and the patient then breathes in and out of it for venty seconds, by which time the carbon-dioxide content the bag is identical with that of the alveolar gas and of e mixed venous blood

Estimation of the carbon-dioxide content can be done apidly with an infra-red analyser or somewhat less apidly by the Haldane method or any of its modifications This procedure promises to be of great value in routine linical work, because it will show an element of hyper-arbia in many acute states in which it has not been uspected (Griggs et al 1958)

Perfusion Zone

The study of this zone consists essentially in measurements of flow and pressure in the pulmonary circulation Cardiac catheterisation now enables pressures to be measured at all points from the great veins up to the " wedge " point, when the pressure closely approximates to that in the pulmonary veins and in the left auricle Flow for periods of several minutes is measured by dividing the arteriovenous difference across the lung into the amount of oxygen taken up (Fick principle) or by the use of tracer substances such as Evans blue, Coomassie blue, or radioactive substances such as ^{24}sodium or ^{131}iodinated albumin

As regards pulmonary pressures, hypertension is the usual defect It is due to physical reduction of the vascular bed (as in emphysema), or obstruction of the vessels (as in multiple pulmonary embolisation), or low oxygen tensions (as in long-continued hypoventilation) (Cournand 1950) In many slowly progressive pulmonary disorders the hypertension may not be apparent at rest but is obvious during exercise The normal pulmonary vascular bed can accommodate a several-fold increase in flow with only a slight elevation of the pressure However, when vessel walls are diseased or the oxygen tension of the inspired air is low, the same increase in flow causes very pronounced hypertension This illustrates the great value of " testing under load ", which is in many respects of much greater importance than merely ascertaining resting values (Riley et al 1948)

Ventilation-perfusion ratio

A consideration of the combined influence of ventilation and perfusion leads to the important concept of the ventilation-perfusion ratio (Riley and Cournand 1949) It has always been clear that the proportion of carbon dioxide eliminated to oxygen absorbed—i e, the respiratory quotient—for the whole body is determined by the metabolic behaviour On an average mixed diet this ratio is 0 8

Thus the proportion of ventilation to perfusion in the lungs must be set so as to effect this exchange This does not, of course, mean that each alveolus must have precisely the same exchange ratio, but the mean level of all alveoli must conform If the whole lung, a lobe of a lung, or a single alveolus is hyperventilated, then an abnormally great quantity of carbon dioxide is eliminated but very little extra oxygen can be taken up that is to say, the exchange ratio is greater than unity On the other hand if ventilation be subnormal, or—what comes to the same thing—perfusion is disporportionately great, then the elimination of carbon dioxide will be reduced more than the absorption of oxygen This situation is seen in its most extreme form when an airway is completely blocked and the gas exchange is so slight that the bubble comes virtually into gaseous equilibrium with mixed venous blood

It is clear that in many disease conditions this delicate proportion between ventilation and perfusion is disturbed in varying degrees ranging from scattered alveolar dysfunction through a lobe or single lung up to disturbance of the whole respiratory system

Lung Mechanics

An important development in the physiology of respiration was an analysis of the mechanics of ventilation by a study of the simultaneous pressure-volume values during a single respiratory cycle (Rohrer 1915) This method is the basis of a mathematical consideration of the function of reciprocating steam engines, internal-combustion engines, and pumps

A force which has to be overcome in ventilation is resistance to stretch of the lungs and chest wall, which during normal respiration behave as an elastic structure in the middle or rectilinear part of its expansion/contraction range This resistance obviously increases with increasing depth of respiration, and if it were the only opposition to respiration a plot on x and y axes of the simultaneous values of pressure and volume of a respiration would yield a straight line the angle of which would be a measure of the resistance of the lung and chest wall to stretch

Other non-elastic forces are developed in moving air through the air-passages and in moving tissue planes over each other These increase with the speed of breathing and disappear altogether for a brief period at the height and depth of respiration The effect of this non-elastic resistance is to deviate the pressure/volume trace from a rectilinear form In fact, its normal form is that of an ellipse, the area of which is proportional to the work done in overcoming non-elastic resistance whereas the area of the right-angle triangle of which the long axis of the ellipse forms the hypotenuse is proportional to the work done in overcoming elastic resistance This type of analysis is proving a useful diagnostic tool, because it differentiates sharply between respiratory disability due principally to airway obstruction and disability due principally to diffuse stiffening of the lungs With airway obstruction the area of the loop is much increased, indeed, it may become roughly circular With stiffening of the lungs, on the other hand, the chief alteration is in the slope of the long axis in the direction which indicates a reduction in change of volume per unit of pressure change—i e, a reduction in what is known technically as the " compliance " (Fenn 1951, Christie 1953)

The measurements for this sort of study are first of all the volume displacement during a breath, which is readily measured with a flowmeter connected to a mouthpiece or by a special lightweight spirometer (Arnott, Butler, and Pincock 1954) Intrathoracic volumes are obtained from a balloon placed in the œsophagus Volume displacements and intraœsophageal pressures give the mechanical behaviour of the lungs alone, but if the subject is enclosed in a Drinker-type respirator and is breathed passively, the pressure changes in the casket compared with the volume displacements give a mechanical picture of the thoracic cage along with the lungs The difference between these two sets of measurements yields a value for the work done, both elastic and non-elastic, in moving the chest walls alone

Causes of Respiratory Failure

Just as the functional assessment of the respiratory system falls naturally into certain zones, so the diseases impairing respiration can be grouped correspondingly

Ventilatory impairment is due to any process which interferes with the normal function of the bellows mechanism, either in its moving parts or in its control mechanism Probably the commonest causes are those which lead to airway obstruction, such as bronchitis, emphysema, asthma, and tracheal compression There are processes which interfere with the action of the thoracic cage or pleura—e g , kyphoscoliosis, ankylosing spondylitis, gross obesity, injury to the chest wall (either accidental or operative), scleroderma, pleural effusion, thickened pleura, and pneumoconiosis Neurogenic control may be impaired by an intracranial disease (vascular, neoplastic, or traumatic), barbiturate poisoning, paralytic poliomyelitis, polyneuritis, myasthenia gravis, progressive muscular atrophy, porphyria, or muscle-relaxant drugs of the curariform type

Ventilatory function may also be upset temporarily by a psychological crisis such as hysterical overbreathing

Diffusion defects may arise from any condition which interposes on an extensive scale any new material—be it fluid, cellular tissue, or connective tissue—between alveolar air and capillary blood Among such conditions are pulmonary œdema, which leads to both free fluid in the alveoli and fluid separating the alveolar and capillary walls (e g , in chronic left-sided cardiac failure and particularly mitral-valve disease) and also disorders which are associated with a diffuse overgrowth of tissue (e g , sarcoidosis, pneumoconiosis, berylliosis, scleroderma, radiation fibrosis, pulmonary histiocytosis, lymphangitic carcinomatosis, and the peculiar diffuse inflammatory process called the Hamman-Rich syndrome) (Arnott 1959)

Pressure defects arise in any process which impairs the flow of blood through respiratory capillaries In its most extreme form it may be the result of the lodgment of an embolus in the main pulmonary artery—a process which so much interferes with circulation as to cause rapid death On the other hand blockage of a right or left pulmonary artery, by an embolus or surgical treatment, results in surprisingly little functional impairment The vascular bed of the remaining lung, provided it is reasonably healthy, can dilate sufficiently to accommodate the entire blood-flow without any great elevation of pressure When a lung is removed, functional impairment is comparatively slight, but when blood-flow to the lung is greatly reduced though ventilation remains normal, a serious ventilatory defect results which takes the form of a greatly increased dead-space effect Localised vascular disease, such as may be caused by tuberculosis, bronchiectasis, injury, or neoplasm, is not as a rule of serious functional moment, because any disturbance of ventilation/perfusion ratio can be compensated by the normal areas Diffuse vascular disease is an important cause of pulmonary hypertension, and may be due to such processes as multiple embolisation from thrombophlebitis and chorionepithelioma (Bagshawe and Brooks 1959) or may be the reflection of cardiac disease such as mitral stenosis and left-to-right shunting

Pathological Mechanisms

Apart from extrathoracic disease interfering with the central control of respiration, the principal structural effects of disease can be regarded as

(a) Airway obstruction
(b) Stiffening of lungs with increase of the diffusion pathway
(c) Reduction of pulmonary vascular bed

The principal functional effects of respiratory disease are

(a) Arterial unsaturation with consequent cyanosis and a varying degree of polycythæmia

(b) Where alveolar ventilation is subnormal, carbon-dioxide retention occurs, which in time leads to a diminished sensitivity of the respiratory centre to carbon-dioxide and progressive hypercapnia

(c) Retention by the body of base (mainly sodium bicarbon order to buffer the retained carbon dioxide, aggravates the pul hypertension and the œdema

(d) Pulmonary hypertension with consequent right hypertrophy and ultimately failure with systemic venous hyp and œdema

In the early stages of respiratory disease these effects become apparent only during exercise instance, until emphysema is advanced, the arterial saturation is normal at rest though it may drop ably during exercise Similarly the pulmonary pressure may be normal at rest for a time but rises qu abnormally during exercise

Clinical Picture of Ventilatory Failure

The common cause of this syndrome is airway obstruction resulting from inflammatory reaction of the lin mucosa This is a common consequence of infection (as bronchitis following coryza or influenza), an allergi stimulus (as in asthma), or chemical damage (as in th inhalation of tobacco smoke or industrial pollution) Wit this air-passage inflammation there is often emphysem which, whatever its origin, is certainly associated wit faulty air distribution, alveolar hypoventilation, muc distortion of the ventilation/perfusion ratio, a reduce pulmonary vascular bed, and pulmonary hypertension

In recurrent bronchitis—the commonest cause o ventilatory disability—patients tend to show a steady leve of respiratory disability with periodic crises of acut respiratory failure due to respiratory infection, allergi attacks, or severe atmospheric pollution

Respiratory failure is marked by dyspnœa the effort o breathing increases because the airway is obstructed by swollen mucosa and, above all, retained secretions If emphysema is severe the position of the thoracic cage is mechanically embarrassing Additional factors causing dyspnœa are carbon-dioxide retention, to which the respiratory centre is only partially acclimatised, and hypoxia which stimulates the carotid-sinus and aortic chemoreceptors In all severe cases there is cyanosis due to arterial desaturation if not obvious at rest, it is plain after exercise such as a bout of coughing The most obvious effects of carbon-dioxide retention are principally in the nervous system Here one must admit that there is not yet any clear separation between the neural effects of hypercarbia and anoxia, but at any rate both processes are present in respiratory failure of ventilatory origin, and are responsible for mental confusion which in the past has been regarded uncritically as toxic or febrile delirium The patient is forgetful, and a few questions—" what day of the week is it ? ", " what did you have for breakfast ? ", " which party won the election ? "—may at once uncover a gross abnormality Such patients tend to be drowsy and the relatives may complain that they fall asleep in the middle of a conversation Coarse irregular muscle twitching is usually present and can be clearly seen when the patient stretches out his arms with the wrists dorsiflexed The twitching resembles the " liver flap " of hepatic failure

The hypercapnia may be associated with an exacerbation of congestive cardiac failure, shown by distended neck veins and gross œdema The extremities are warm, the pulse is full, and the blood-pressure slightly raised (Westlake, Simpson, and Kaye 1955) The differential diagnosis of such a state of respiratory failure is greatly helped by the background of the patient Except during epidemics of virulent influenza, the syndrome rarely develops suddenly in a person who has not been obviously

The patients are usually known bronchitics and their [illegible] attack is precipitated by an infection of the upper [illegible] tract, the whole syndrome arising commonly in [illegible] about a week after the commencement of an attack the prevailing epidemic The circumstances of the event should prevent any confusion with attacks of pulmonary œdema due to hypertensive cardiac failure, myocardial ischæmia, or mitral stenosis The respiratory failure can be conclusively demonstrated by finding oxygen unsaturation and raised carbon dioxide in a sample of arterial blood Even more simply the determination of the alveolar carbon dioxide by the Campbell-Howell method will confirm the diagnosis

At hospitals making systematic tests of arterial blood gases or alveolar carbon dioxide respiratory failure is found, often unexpectedly, in a substantial proportion of middle-aged or elderly people with congestive cardiac failure who have been regarded as victims of coronary vascular disease and whose underlying respiratory condition has been inadequately assessed The effect of giving such patients pure oxygen may confirm the diagnosis (Donald 1949) The elevation of the oxygen tension of the inspired air rapidly offsets the alveolar hypoventilation in respect of oxygen, cyanosis is abolished and the patient is soon pink and placid—far too placid in fact, for he may sink into coma with aggravation of the muscle twitching The rate of respiration decreases and its amplitude is less Owing to the insensitivity of the respiratory centre to carbon dioxide, the respiratory drive of such patients depends unduly on the hypoxic stimulus Once this is corrected, ventilation becomes less and carbon-dioxide retention increases—perhaps dangerously

In patients in whom the respiratory element has not been recognised and who have been treated along conventional lines for cardiac failure, the response to digitalis and diuretics is often very slow, but when the ventilatory insufficiency is corrected the pulmonary pressure falls, venous congestion subsides, and œdema disappears

Treatment of Respiratory Failure of Ventilatory Origin

When a patient presents the sort of picture I have described, the aim of treatment is to improve alveolar ventilation Antibiotics are necessary for the infection, which is usually important In a severe case full doses of penicillin and tetracycline are useful The removal of secretions can be assisted by a steam tent, which, old-fashioned though it may be, is an excellent means of keeping mucus fluid Aerosols may help, and if there is any bronchospasmic element isopropyl-noradrenaline should be included in the aerosol Oxygen should be given, preferably in a tent because such patients do not readily retain a mask or nasal catheter A close watch should be kept for any increasing stupor or convulsions To prevent these, the period of oxygen breathing may be only forty minutes in the hour, followed by twenty minutes breathing room air, but marked hypercarbia is an indication for more ventilation *not* for less oxygen In ventilatory failure the use of 5% carbon dioxide in oxygen is, of course, completely wrong

Ventilation can be stimulated chemically by the use of aminophylline (2 5% solution) and nikethamide (25% solution) given in an intravenous drip under the close personal supervision of the physician Large doses are usually necessary, and the amount required is that which produces the required increase in ventilation without (in the case of aminophylline) nausea and vomiting or (in the case of nikethamide) troublesome convulsions Hence the need for a physician to keep his hand continually on the drip-cock (Hugh-Jones 1958)

Sometimes all these measures fail, because of the amount and stickiness of the secretions or because one cannot correct cyanosis without depressing ventilation dangerously The treatment then is tracheotomy so that bronchial secretions can be sucked out and a positive-negative pressure respirator (e g , of Smith-Clark type) can be connected to the tracheal opening This may save a moribund patient (Davidson 1959) Once the whole ventilatory mechanism is under artificial control, the risk of hypercarbia has gone the blood carbon-dioxide tension is likely to revert to normal within an hour or two and the general electrolyte balance should be normal within two or three days The risks of respiratory depressant drugs—particularly morphine preparations—are obvious, although once tracheotomy with artificial respiration is established their depression of the respiratory centre is no longer of consequence

When the role of respiratory failure was first recognised and these active therapeutic measures were introduced it was thought that the improvement might only be transient and would rarely enable the patient to regain anything approaching a useful life But the extent of recovery may be very great, indeed, many patients rescued from an acute attack of respiratory failure have remained in good health indefinitely

Application of the principles I have outlined would considerably improve the outlook in cases of chronic ventilatory defect With differences appropriate to the causal disease, this picture of ventilatory failure is reproduced in many disorders—all of them having the capacity to cause alveolar underventilation

Some less familiar causes of respiratory insufficiency and failure have been recognised recently

The grossly obese, with weights above 20 st , often have quite severe respiratory inadequacy (Hackney et al 1959) Not only are they dyspnœic on slight exertion but they are often mentally sluggish and drowsy This has been shown to be due to carbon-dioxide retention The defect here is the great weight of the thoracic integument and the high intra-abdominal pressure caused by the massive deposits of fat The expiratory reserve volume is much reduced and the ratio of dead-space air is increased All this leads to defective alveolar ventilation, habituation of the respiratory centre to high pCO$_2$, and chronic anoxia Polycythæmia, pulmonary hypertension, and ultimately congestive cardiac failure supervene

Gross thoracic deformity of the kyphoscoliotic type has long been known to terminate sometimes in congestive cardiac failure Recent studies have shown that this is cardiorespiratory failure, the result of alveolar hypoventilation and cor pulmonale It is due to an unusual pattern of breathing which, while it minimises the work and energy required to move the deformed chest, is nevertheless insufficient to secure adequate alveolar ventilation An additional factor in these people is that the pulmonary vascular bed is smaller than normal (Bergofsky et al 1959)

Alveolar-capillary Block Syndromes

As already explained, any process which increases the diffusion pathway so much that it seriously impairs oxygen saturation of hæmoglobin will produce the alveolar-capillary block syndrome Many of the usual causes have been enumerated (Arnott 1959, 1960) The clinical picture varies to some extent according to the causal process, but, provided this is comparatively gradual in its onset (as in sarcoidosis), the first disturbance is dyspnœa This is not the laboured obstructed breathing found in chronic bronchitis or asthma, for the greater ventilatory volume is secured mainly by an increase in the rate rather than the depth of respiration At first this increase is noticeable only on exercise, but, once the disorder is established, the resting respiratory rate is at least 20 per minute, and in the later stages it may be continually as high as 35–40 with little slowing during sleep While still approaching the bedside I have been able to make the diagnosis from the chart, which showed the respiratory rate to have been around 30, with little or no fever, for many days Orthopnœa is absent except when pulmonary hypertension has led to right heart-failure

The cause of this accelerated respiration is probably the generalised stiffening of the lungs, which means that depth of respiration is attainable only by an inordinate expenditure of work From the ventilatory angle the rapid, rather shallow, breathing is inefficient in that it exaggerates the dead-space effect, which reduces alveolar ventilation For a time at least, an increased diffusion pathway can be compensated by an elevation of alveolar oxygen tension, through better ventilation Normally the oxygen tension of room air is about 150 mm whereas that of alveolar air is about 104

The diffuse stiffening of the lungs has led to the clinical phenomenon which has come to be known as the " door stop " sign This is observed when the patient is asked to take a deep inspiration and the effort is arrested abruptly

I well remember a patient with a diffuse alveolar-capillary disorder in whom bronchoscopy was carried out under general anæsthesia Having inserted a tracheal tube and given a muscle-relaxant drug, the anæsthetist settled down to ventilate the patient by rhythmic contraction of the bag He soon discovered that his compression of the bag was opposed firmly by the indistensibility of the patient's lungs The extensive thickening of alveolar walls which was demonstrated at necropsy some weeks later amply explained this defect

Tachycardia is quite often present From an early stage there is usually some arterial unsaturation, but only when the disease is well established is this sufficient to cause cyanosis, and only in the late stages is the cyanosis evident during rest it can be abolished by raising the oxygen tension of the inspired air Clubbing of the digits is variable in occurrence and is associated with an abnormally large blood-flow in the terminal phalanges, the precise cause of which is unknown Most patients with alveolar-capillary block have a cough, but sputum is usually scanty and non-purulent They usually experience extreme fatigability from an early stage, and by the time arterial unsaturation is substantially at rest they lose weight The general upset depends on pure anoxia without the carbon-dioxide poisoning seen in ventilatory obstruction In this respect the picture approximates to mountain sickness Although oxygen-lack by itself causes headache, anorexia, and some mild confusion with hallucinations, the mental state is usually comparatively clear until near the end—in contrast to cases with ventilatory defects, in which carbon-dioxide retention causes stupor and twitching

Polycythæmia is seldom present—probably because the whole course of alveolar-capillary block is rarely long enough to allow of this adaptation

Clinical examination of the chest usually shows little abnormality other than some moist accompaniments Prolonged expiration and dry sounds of bronchial obstruction are absent As many of the causes of alveolar-capillary block involve the pulmonary vascular bed, pulmo hypertension with its liability to congestive cardiac fa is often present

The extent and character of radiological changes dep very much on the cause of the syndrome It is impor to realise that a patient with a severe degree of block show virtually no radiological changes, or a diffuse mottling Obliteration of costophrenic angles and pro ence of fissure lines may be visible

The principal physiological changes are the incre alveolar-capillary gradient with arterial unsaturation a normal or reduced arterial carbon-dioxide content alveolar carbon dioxide is also normal or reduced T arterial unsaturation can be fully corrected by inha oxygen

A spirogram shows no evidence of obstruction total capacity and total lung capacity are reduced, aln entirely through curtailment of the inspiratory capa

Pressure/volume curves of the respiratory cycle sho reduced compliance, as the result of the stiffening of lungs, with a normal non-elastic component indica free airways

As the airways are not involved, pulmonary mix is normal and tests of maximum breathing capa (such as the peak expiratory flow-rate) give values eit low normal or very slightly impaired These values much better than they would be if the syndrome were to ventilatory defect

Although the diagnosis of alveolar-capillary block, to precise, requires considerable cardiorespiratory laborat resources, a reasonable diagnosis can be made on the b of dyspnœa, hyperventilation, and tachypnœa, in presence of diffuse finely dispersed radiological pulmon lesions and the absence of bronchial obstruction emphysema The diagnosis will be strengthened if th is post-exercise cyanosis which can be completely abolis by breathing oxygen

There is, of course, a wide range of possibilities as to disease which may be causing the defect One whic have already mentioned is the curious disorder which come to be known as the Hamman-Rich syndrome (Ru and Lubliner 1957) This begins usually as a respirato tract infection of the inflammatory type but goes on develop the clinical picture of alveolar-capillary bl leading to death within a few months The alveolar se are found to be diffusely thickened with young connect tissue, and the alveolar endothelium instead of be extremely thin becomes cuboidal or even columnar

Treatment of the alveolar-capillary block syndro must be directed at the causal process For instance, t treatment of sarcoidosis with corticoids is often successf and radiation reaction, provided no further radiotherapy given, sometimes subsides satisfactorily Unfortunate many of the causes are irreversible end-stages of disea Anoxia is treated by oxygen inhalation, but where t disease is progressive the patient will become increasin dependent on his oxygen lifeline There is no physiolo cal objection to oxygen therapy, for, in contrast to cas of ventilatory insufficiency, carbon-dioxide retention absent Any concurrent factor which causes bronch obstruction, such as inflammation or hypersensitivit should be treated appropriately

Conclusion

I hope I have made it clear that order and disorder pulmonary function (Arnott 1955) can be interpreted the basis of physical chemistry and that much that w previously obscure thus becomes logical and leads naturally to rational treatment.

We have to recognise the importance of respiratory insufficiency in such common conditions as bronchitis, bronchopneumonia, chest-wall injuries, and barbiturate poisoning Informed and intelligent treatment of such disorders will save lives

It is a great pleasure to acknowledge the debt I owe to my colleagues who have tried so hard to guide me in this field, in particular Prof Kenneth Donald, Prof Owen Wade, Prof A L d Abreu, Dr George Whitfield, Dr John Bishop, Dr Peter Harris, and Dr John Butler

CERTAIN drugs, such as acetylphenylhydrazine, when given to normal subjects in sufficiently high dosage, cause hæmolysis A different kind of drug-induced hæmolysis depends on hypersensitivity to a particular drug or drugs Two mechanisms for this have been described

1 The drug may be adsorbed to the red blood-cells, and, with the drug-erythrocyte complex as antigen, "autoantibodies" are formed which subsequently destroy the patient's erythrocytes in the presence of the drug

2 The erythrocytes, because of an inherent enzyme defect, are sensitive to the hæmolytic action of drugs in doses which are not normally harmful (Beutler et al 1954, 1955, Carson et al 1956)

Harris (1956) was the first to give a complete report of an example of the first mechanism he described a case of sensitivity to the antimony-containing drug, stibophen A similar mechanism has been described in hæmolysis due to such drugs as quinidine (Freedman et al 1956), methoin (Snapper et al 1953), and quinine and phenacetin (Muirhead et al 1958)

The second mechanism is now known to be responsible for the hæmolytic episodes which sometimes follow treatment with primaquine (Dern et al 1954), nitrofurantoin (Kimbro et al 1957), sulphonamides and *p*-aminosalicylic acid (P A S) (Szeinberg et al 1957), and vitamin-K substitutes (Zinkham and Childs 1957) and in favism (Szeinberg et al 1957)

We report here the production of hæmolysis and acute renal failure in two patients, of whom one was sensitive to phenacetin and the other to P A S In each case the presence of an "autoantibody" was demonstrated

Phenacetin Sensitivity

Phenacetin was introduced in 1887 as an antipyretic and analgesic agent Despite its widespread clinical use, there are few records of side-effects

Smith (1958) noted that skin eruptions, cyanosis due to the production of sulphhæmoglobin and methæmoglobin, and anæmia were the commonest toxic manifestations In addition he referred to renal damage, indicated by hæmaturia, casts, and occasionally oliguria with azotæmia, but detailed case-reports were not given Wuhrmann and Jasinski (1955) described 35 cases of toxic hæmolytic anæmia after phenacetin ingestion. Females were predominantly affected and an association with pre-existing iron-deficiency anæmia was stressed The possibility of a sex-linked abnormality of the red-cell-enzyme system was suggested. Marti (1958) recorded anæmia, probably due to hæmolysis, in half of 70 cases of chronic phenacetin overdosage Meischer and Pletscher (1958) found that the mean red-cell life in patients taking 1–2 g of phenacetin daily was diminished (but only to levels which a normal bone-marrow could have rectified)

An exact mechanism of hæmolysis due to phenacetin was not described until Muirhead et al (1958) demonstrated, in a single anæmic patient, a phenacetin-dependent antiglobulin reaction Phenacetin-induced hæmolysis associated with red-cell enzyme (glucose 6-phosphate dehydrogenase) deficiency has not been reported Dern et al (1955) showed, however, that red cells from primaquine-sensitive individuals, when transfused into normal subjects are hæmolysed by other drugs, including phenacetin.

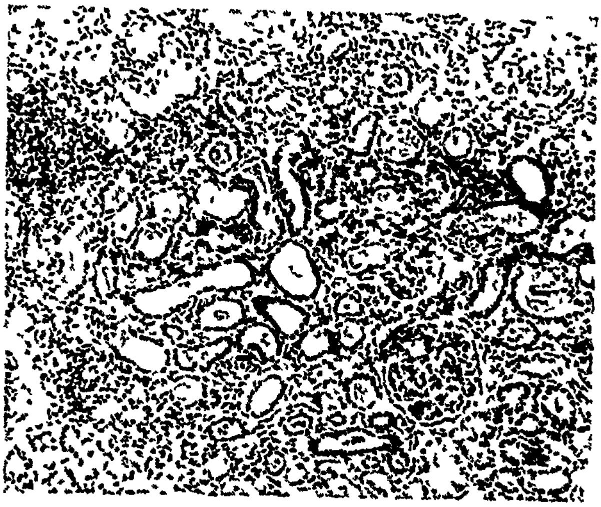
Although the hæmolytic effect of phenacetin has been recognised, acute oliguric renal failure has not been described The kidneys have, however, been reported to suffer damage after prolonged administration Spuhler and Zollinfoe (1953) recorded "primary chronic interstitial nephritis" at necropsy in phenacetin poisoning, and raised the question of renal damage in chronic takers of the drug Lindeneg (1959), too, has correlated chronic renal impairment with long-term phenacetin habituation and suggests that renal papillary necrosis might possibly be caused in this way

CASE ONE

A 38-year-old white woman was admitted to Dartford Hospital in April, 1958, with jaundice and oliguria of 48 hours' duration. 5 months earlier she had had a similar episode, lasting several weeks, with vomiting, malaise, and jaundice but without obvious disturbance of kidney function. Apart from a history of scarlet fever with nephritis at the age of 7 years, there was no evidence of pre-existing renal disease, in particular she had had no nocturia, dysuria, or œdema

Examination and Investigations

The patient was anæmic, with icterus of the conjunctivæ No skin rash was noted, and there was no œdema. The spleen was moderately enlarged and both kidneys were palpable The liver was not enlarged



Case 1: renal biopsy specimen taken during diuretic phase of first illness, showing pronounced interstitial cellular infiltration (× 96.)

Investigation showed a hæmoglobin level of 7·6 g. per 100 ml. and a blood-urea of 233 mg. per 100 ml. In view of this finding and of persistent anuria, the patient was transferred to Hammersmith Hospital for possible treatment by hæmodialysis with an artificial kidney.

Further investigations on admission showed that the hæmoglobin level was unchanged at 7·8 g. per 100 ml.; the packed-cell volume (P.C.V.) was 24·5% and the mean corpuscular hæmoglobin concentration (M.C.H.C.) 32%. The leucocyte-count was 4500 per c.mm. and the platelet-count 160,000 per c.mm. The peripheral-blood film showed anisocytosis, with microcytosis, slight polychromasia, and occasional schistocytes. The patient's blood-group was A, rhesus-positive. The total serum-proteins were 7·1 g. per 100 ml., with albumin 3·7 g. per 100 ml. The blood-urea had risen further to 300 mg. per 100 ml.; the serum-potassium was 6·6 mEq. per litre, with a bicarbonate level of 13 mEq. per litre.

Course

Severe oliguria persisted and the patient was treated by a conservative regime for acute liguric renal failure. The blood-urea reached a peak of 450 mg. per 100 ml. on the 10th day of the illness, at which time a satisfactory diuresis took place. Hæmodialysis was not required, and the subsequent course to recovery was uneventful. The hæmoglobin level did not fall further and was restored to normal by transfusion. Examination of the patient's urine in the diuretic phase, and thereafter, showed no abnormality, and percutaneous renal biopsy revealed the appearances of a recovering tubular necrosis with considerable interstitial cellular infiltration (see figure). There was no evidence of glomerular damage.

Anæmia with tubular necrosis of obscure origin was diagnosed, and the patient returned home after 6 weeks to continue convalescence. For the ensuing 5 months she remained well, the hæmoglobin level was maintained, the blood-urea was normal, and there was no proteinuria. On Oct. 27, 1958, however, she suddenly became ill a few hours after the ingestion of 4 analgesic tablets taken for incipient coryza. The patient stated that her lips and hands became blue and she had a cold sensation in her hands and feet. On the following day she vomited profusely, and voided only a small volume of dark urine. She was observed to be jaundiced, oliguria persisted, and she was readmitted to Hammersmith Hospital.

Readmission

On examination the patient was again anæmic and jaundiced. The kidneys and spleen were enlarged to palpation. Investigations showed a hæmoglobin level of 10·4 g. per 100 ml. and 1·4% reticulocytes. The peripheral-blood film showed slight anisocytosis. No sulphæmoglobin or methæmoglobin was detected, but the serum contained methæmalbumin, and electrophoresis showed absence of haptoglobins. (3 days later only a trace of methæmalbumin was present, and the haptoglobins were normal.) Osmotic fragility was normal. The plasma-bilirubin (indirect-reacting type) was 1·2 mg. per 100 ml.; serum-alkaline-phosphatase was normal, and flocculation tests of liver function showed no abnormality.

Severe oliguria persisted for 10 days, the blood-urea rising to 280 mg. per 100 ml. The protein-anabolic steroid norethandrolone ('Nilevar') was added to the conservative-treatment regime employed during the previous illness, and again hæmodialysis was not required. Following diuresis the patient once more recovered uneventfully, with no evidence of residual renal dysfunction.

Relation of Attacks to Phenacetin

The tablets taken by the patient at the start of the second illness were found to be "A.P.C." and to contain a total dose of 648 mg. of phenacetin. Inquiry established that immediately before her illness in April, 1958, she had taken two 'Veganin' tablets (each containing 250 mg. of phenacetin), and in October, 1957, when she had suffered obscure malaise with jaundice, she recalled having been given two 'Cojene' tablets (each containing 300 mg. of phenacetin). Apart from these three occasions, she denied previously taking any form of analgesic.

It therefore appeared possible that phenacetin was responsible for the episodes of anæmia and acute renal failure. An inherent defect in the patient's red-cell enzymes was first sought as a cause for the sensitivity, but the glutathione-stability test (Beutler 1957) was normal. The direct antiglobulin test, on the other hand, was weakly positive. This suggested that the hæmolysis might be due to an autoantibody mechanism.

The patient's serum was then found to contain a factor which, in the presence of phenacetin but not in its absence, was capable of sensitising normal red cells of the patient's blood-group to agglutination by antiglobulin serum. Further hæmatological studies were then undertaken to define the properties of the serum factor more exactly.

The direct antiglobulin reaction was apparently of the non-γ-globulin type—that is to say, the red cells were agglutinated by an antiglobulin serum to which human γ-globulin had been added. However, when the indirect test was carried out using patient's serum, phenacetin, and normal red cells, the non-γ-globulin reaction was shown to be due to the adsorption of complement. When the test was repeated using heat-inactivated patient's serum and phenacetin it was still positive using the normal antiglobulin reagent (no γ-globulin added) but negative with antiglobulin serum to which γ-globulin had previously been added.

The antibody thus appeared to be potentially hæmolytic in vitro, and this was confirmed by the demonstration that the patient's serum, with added phenacetin, brought about the hæmolysis of trypsinised normal red cells and P.N.H. (paroxysmal nocturnal hæmoglobinuria) red cells in the presence of human serum complement. Hæmolysis of normal (untrypsinised) red cells could not be demonstrated. Normal red cells were, however, agglutinated to approximately the same serum dilutions that produced positive antiglobulin tests (table I).

TABLE I—AGGLUTINATION, HÆMOLYSIS, AND SENSITISATION TO ANTIGLOBULIN SERUM BY ANTIBODY PRESENT IN SERUM OF CASE 1

Cells tested	Dilution of patient's serum			Agglutination and lysis
	1 in 1	1 in 4	1 in 16	
Normal	++	±	0	Agglutination (diluent saline)
Normal trypsinised	±	+	0	Lysis (diluent fresh normal serum)
P.N.H.	++	+	0	Lysis (diluent fresh normal serum)
Normal (indirect Coombs test)	+++	+	0	Agglutination (diluent fresh normal serum)

In each test phenacetin was present at a final concentration of 3·3 mg. per 100 ml.

Readings of agglutination and lysis were made after 2 hours at 37°C.

+++, ++, +, ± indicate grades of agglutination and lysis.

TABLE II—SENSITISATION OF NORMAL RED CELLS TO ANTIGLOBULIN SERUM, IN PRESENCE OF VARYING AMOUNTS OF PHENACETIN, BY ANTIBODY PRESENT IN SERUM OF CASE 1

Dilution of patient's serum in fresh normal serum			Final concentration of phenacetin (mg. per 100 ml.)
1 in 1	1 in 4	1 in 16	
+++	++	0	10·0
+++	++	0	5·0
+++	+	0	2·5
+++	+	0	0·5
+++	±	0	0·05
++	±	0	0·025
±	trace	0	0·005
±	trace	0	0·0025
trace	0	0	0·0005
0	0	0	0·0001

The tests were read after 2 hours at 37°C.
+++, ++, +, ± indicate grades of agglutination.

In all the above experiments control tests using normal serum and phenacetin, patient's serum without phenacetin, and phenacetin alone were set up. No agglutination, hæmolysis, or sensitisation to antiglobulin serum was demonstrated in any of these control tests.

Concentration of Phenacetin and Serum Titre (Table II)

Phenacetin was added to the patient's serum in final concentrations ranging from 10 mg. per 100 ml. to 0·1 µg. per 100 ml. Positive reactions were obtained within the range 10 mg. to 2 µg. per 100 ml. Employing the antiglobulin reaction as a means of detecting sensitisation the maximum titre of antibody demonstrated was 16.

The antibody at first gained in strength with time. Within a few days of the second hæmolytic episode the maximum titre demonstrated, using the agglutination of normal cells, was 2; 3–4 weeks later it was 8; 7 weeks after the onset of hæmolysis it was 16. The titre had fallen to 2 when serum was tested 9 and 24 weeks later.

Reaction with Other Drugs

Drugs chemically unrelated to phenacetin, but known to be capable of causing hæmolysis by a similar mechanism (e.g., quinidine and methoin), did not, in the presence of this patient's serum, sensitise normal red cells to agglutination by antiglobulin serum. Neither did P.A.S., *p*-aminobenzoic acid, sulphadiazine, procaine hydrochloride, and probenecid. On the other hand, the in-vivo metabolic products of phenacetin—paracetamol ('Panadol') and para-phenetidine—both produced positive reactions. Whereas phenacetin was effective in a final concentration as small as 2 µg. per 100 ml., the necessary minimum concentrations of paracetamol and para-phenetidine were 1·7 mg. and 1 mg. per 100 ml. respectively.

P.A.S. Sensitivity

Since its introduction in 1944, P.A.S. has been widely used in the treatment of tuberculosis, and numerous toxic effects have been reported.

The most serious of these have been liver and kidney lesions (Cuthbert 1950, Livingstone and Street 1950, Mann 1953, Cannemeyer et al. 1955, Hensler et al. 1957) and hæmolysis. Renal damage in the absence of other lesions seems rare, but has been recorded (Owen 1958). Dérot et al. (1956) reported a case of fatal anuria following the intravenous administration of P.A.S. solution. But, although these workers state that there was no clinical evidence of hæmolysis, no hæmatological investigations are recorded. However, on one occasion before her acute reaction to the final P.A.S. infusion, the patient had had lumbar pain, and the terminal oliguria was preceded by the passage of a few millilitres of red urine. Hæmolysis is a well-known but rare complication of P.A.S. therapy. It has been reported most commonly within 24 hours of taking a small oral dose of the sodium salt of P.A.S. in solution, without previous exposure to the drug (Janet et al. 1951, Tondi 1951, Christiaens and Goudemand 1952, Castanier et al. 1954, Claps 1957, Rowland 1958). Phenolic substances have been isolated from the urine in some of these cases (Christiaens and Goudemand 1952, Castanier et al. 1954, Claps 1957). A direct toxic action on the red cells by some degradation product of P.A.S. has been suggested as the most likely explanation of the hæmolysis. Some experimental evidence in support of this was obtained by Castanier et al. (1956). All but one of a group of rabbits given daily doses of discoloured preparations of the sodium salt of P.A.S. died, while all the controls given unaltered P.A.S. survived.

In some cases acute hæmolysis did not begin until after 15 or more days of treatment with the sodium salt of P.A.S. in solution (Semelaigne et al. 1950) or as tablets (Burkens 1951). In one instance a skin rash was noted at the time of onset of the hæmolysis (case of M. Semelaigne 1950, more fully reported by Christiaens and Goudemand 1952). The delayed type of hæmolysis may have a different pathogenesis, but may only be related to differences in the preparations of P.A.S. employed. Erythrocyte-enzyme defects have been sought in two cases of hæmolysis due to P.A.S. (Szeinberg et al. 1957, Sansone and Segni 1958) and in one (Szeinberg et al. 1957) a low level of reduced glutathione was found. However, no details are given, either about the type of P.A.S. administered or about blood and urine findings at the time of hæmolysis. No immunological mechanism seems to have been described so far for hæmolysis due to P.A.S.

CASE TWO

A 73-year-old man was found to have pulmonary tuberculosis in 1956 and received treatment with 'Pycamisan' (containing P.A.S. and isoniazid) irregularly for an uncertain period. In April, 1959, reassessment revealed persistent active infection, and *Mycobacterium tuberculosis* was cultured from the sputum. The hæmoglobin was 12·5 g. per 100 ml. and the blood-urea was 44 mg. per 100 ml.

On April 23, 1959, a second course of chemotherapy was started using streptomycin 1 g. daily, P.A.S. 12 g. daily, and isoniazid 300 mg. daily. The patient's general condition improved over the next few days. Examination of the urine on April 29, 1959, showed minimal proteinuria and a scanty growth of *Staphylococcus aureus* on culture. There was no pyuria, and the blood-urea remained at 45 mg. per 100 ml. No records of urinalysis before the start of chemotherapy are available.

Onset and Course of Hæmolytic Anæmia

On May 7, 1959, after 2 weeks' treatment, the patient became drowsy and anorexic, and the blood-pressure fell to 110/50 mm. Hg. The blood-urea had risen to 124 mg. per 100 ml. although the serum-electrolytes were normal. In consequence the streptomycin was withdrawn. On the following day, the urine was dark brown, it contained more protein than before but no red cells. The hæmoglobin had fallen to 3·9 g. per 100 ml.

Hæmolytic anæmia was diagnosed, and the remaining drugs—P.A.S. and isoniazid—were withdrawn. Prednisolone, 10 mg. t.d.s., was given in an attempt to control the hæmolysis. During the next 48 hours the patient's condition deteriorated rapidly, the blood-pressure fell profoundly and he was treated with noradrenaline and blood-transfusion. Complete anuria, preceded by oliguria of uncertain duration, was now present, and he was transferred to Hammersmith Hospital for possible treatment by hæmodialysis with an artificial kidney.

On arrival, he was semicomatose with deep respirations. There was a generalised fine macular rash suggesting a drug-sensitivity reaction. The blood-urea had risen to 375 mg. per 100 ml., and the serum-bicarbonate level had fallen to 17 mEq per litre. The serum-potassium was 4·5 mEq per litre and serum-bilirubin 6·1 mg. per 100 ml. The hæmoglobin was 5·8 g. per 100 ml., and methæmalbumin and free hæmoglobin were present in the serum, haptoglobins were absent. The peripheral-blood film showed evidence of autohæmagglutination, and numerous normoblasts were present. There was marked spherocytosis, anisocytosis, and polychromasia. The

TABLE III—AGGLUTINATION, HÆMOLYSIS, AND SENSITISATION TO ANTI-GLOBULIN SERUM BY ANTIBODY PRESENT IN SERUM OF CASE 2

Cells tested	Dilution of patient's serum				Agglutination and lysis
	1 in 1	1 in 4	1 in 16	1 in 64	
Normal	+ + +	+ + +	+	0	Agglutination (diluent saline)
Normal trypsinised	+ +	+ +	trace	0	Lysis (diluent fresh normal serum)
P N H	+ + +	+ + +	+ ±	trace	Lysis (diluent fresh normal serum)
Normal (indirect Coombs test)	+	+ +	±	0	Agglutination (diluent fresh normal serum)

In each test P A S *was present at a final concentration of 40 mg per 100 ml*

Readings of agglutination and lysis were made after 2 hours at 37°C

+ + +, + +, +, ± indicate grades of agglutination and lysis

reticulocyte-count was 4% Osmotic fragility was increased Bone-marrow aspiration showed erythroid hyperplasia The patient's blood-group was A, rhesus-positive

The renal failure was treated conservatively, but attempts to improve the circulatory state prior to hæmodialysis were unsuccessful and the patient died 30 hours after admission Permission for postmortem examination was not granted

A diagnosis was made of hæmolytic anæmia and acute oliguric renal failure due to one of the three chemotherapeutic agents employed

Further Laboratory Investigations

The glutathione-stability test was normal on admission, but, because this could not be repeated, an inherent enzyme defect could not definitely be excluded as contributing to the drug-dependent hæmolysis, since the population of sensitive cells might have been destroyed in the acute hæmolytic episode As in case 1, however, definite evidence for an autoantibody mechanism was obtained

Serology

The serological findings were similar to those in case 1 The direct antiglobulin reaction was positive, and it was of the non-γ-globulin type Two samples of the patient's serum gave the same results Each sample in the presence of P A S agglutinated normal red cells of the patient's blood-group (titre 16), as well as sensitising them to antiglobulin serum, and also agglutinated and hæmolysed (in the presence of complement) trypsinised normal red cells and hæmolysed P N H red cells (table III) The indirect antiglobulin reaction was almost abolished if the patient's serum was heat-inactivated before sensitisation

The activity of the antibody was dependent on the presence of P A S and could be demonstrated using final concentrations of P A S ranging from 10 mg per 100 ml to 500 mg per 100 ml (the highest concentration tested) No abnormal serum activity could be demonstrated in the presence of isoniazid or streptomycin Drugs chemically related to P A S were next tested Positive reactions were obtained with sodium salicylate and sodium *p*-aminobenzoate, but the results were negative with sodium benzoate, sodium *p*-aminohippurate, salicylamide, procaine hydrochloride, phenacetin, paracetamol, paraphenetidine, probenecid, and sulphadiazine

Discussion

These two cases are thought to represent the second recorded instance of an autoimmune type of phenacetin-induced hæmolytic anæmia, and the first report of such a phenomenon due to P A S The association of renal failure with hæmolysis in both cases suggests that the renal damage was secondary to intravascular hæmolysis This is probable in case 2, but less likely in case 1 because the hæmolysis was mild As renal damage has been described as a toxic effect of both phenacetin and P A S, the drug hypersensitivity in these two patients conceivably led to damage to renal cells as well as to red cells The clinical course in each was that of acute oliguric renal failure, characteristic of acute tubular necrosis from any cause In case 1 renal biopsy in the early recovery phase showed only the changes of healing tubular damage—i e, pigmented casts in the tubules with considerable interstitial cellular reaction (see figure) There was no evidence of a longstanding or recent glomerular lesion In view of the serious side-effects of phenacetin in certain individuals, it would seem justifiable to omit this drug from the numerous analgesic mixtures available to the general public

Summary

Of two cases of hæmolysis and acute oliguric renal failure, one followed ingestion of small amounts of phenacetin, and the other treatment with *p*-aminosalicylic acid

In each case the hæmolysis was shown to be due to the production of an autoantibody, acting on the patient's red cells in the presence of the drug

The acute tubular necrosis may have been secondary to the hæmolysis Alternatively, the renal cells may also have been damaged directly as the result of a hypersensitivity reaction

We wish to thank Prof J V Dacie and Dr M D Milne for their advice and interest in the study of these patients

SURGEON LIEUTENANT R.N.

From the Medical Research Council Department of Experimental Medicine, University of Cambridge

Lewis and Love (1926) reported that human skin did not freeze until it was cooled to −2·2°C, and could often be supercooled to much lower temperatures. They made these estimates by pressing metal bars cooled to a known temperature on to the skin. Ungley (1949) and McCance et al. (1956) stated, probably on this evidence, that frostbite could not have contributed to the immersion injuries they reported in men immersed in seawater, which freezes at −1·9°C. R. B. Lewis (1951) reported that when the legs of rabbits were plunged into a freezing mixture the deep temperature of their legs stabilised for a time at about −2·2°C, suggesting that this latter was the true freezing-point of the tissues. However, Smith (1954), Lovelock and Smith (1956), and Appelboom et al. (1958) reported that the true freezing-point of mammalian tissues was close to that of blood, which freezes at about −0·55°C (Margaria 1930).

It therefore seemed important to re-examine by a different technique to that of Lewis and Love (1926) the question of whether human skin can freeze at a higher temperature than −1·9°C, the freezing-point of sea water, and to attempt to measure accurately its true freezing-point.

Methods

The little fingers of healthy men and women aged 18–38 were used in all "in-vivo" experiments. In most cases a rubber tourniquet was applied to the base of the finger to stop the circulation, since without a tourniquet changes in blood-flow caused fluctuations in temperature which interfered with the determination of true freezing-point. A thermojunction made from welded 34-gauge copper-and-constantan wire was either applied to the surface of the finger by zinc-oxide plaster or inserted for a length of 1 cm. into an intracutaneous track made previously in the deeper layers of the epidermis on the pad of the finger by a needle (Keatinge 1957). Another method attempted twice was to strap the two little fingers together with a thermojunction between them. However, the temperature between the two fingers fell so slowly that the risk of injury due to prolonged freezing of the more exposed parts of the finger made it necessary to abandon these experiments before the freezing-point could be determined. On another occasion a subcutaneous needle thermocouple was used. The cold junction of the thermojunction was in a vacuum flask of distilled water and ice, and the electromotive force was led to a direct-reading galvanometer. This apparatus was calibrated and was accurate to ±0·01°C.

Before most experiments the entire finger, with the thermocouple and tourniquet in place, was cooled in a mixture of ice and water until the temperature of the junction had fallen to near 0°C. This required 10 minutes in most cases and rather longer in others. The purpose of pre-cooling was to reduce the thermal gradients in the finger at the time it was put into the brine, and thereby improve the accuracy of estimation of the true freezing-point of the skin. In many cases when several layers of plaster were applied to a finger, it was enclosed in a rubber finger-stall during pre-cooling, to prevent fresh water being absorbed by the plaster and disturbing the freezing-point determination. The finger-stall was removed before the finger was put into the brine. The distal phalanx only was then immersed in a freezing mixture of brine and ice. This was in a circular container and was stirred mechanically so that the mixture flowed steadily past the finger. The temperature of the mixture was measured by a mercury thermometer accurate to 0·01°C, and was kept at −1·9±0·02°C by adding salt when necessary.

Results

Freezing of Fingers in Brine at −1·9°C

Fig. 1 shows the temperature recorded from the surface of the pads of the terminal phalanges of W. R. K.'s and P. C.'s little fingers in brine at −1·9°C. In each case the thermojunction was covered by two strips of zinc-oxide plaster 3 mm. in width, circulation to the finger had been arrested by a tourniquet, and the finger had been pre-cooled in ice and water at 0°C for 10 minutes before it was put into the brine. In brine the temperatures at first fell sharply towards that of the brine, but after 1 minute in the case of P. C. and 1 minute 15 seconds in the case of W. R. K., they rose rapidly to about −1·2°C, remained at this level for about 1 minute and then drifted slowly downwards again. Each finger was removed from the brine after 7 minutes, and at the end of this time they felt and sounded hard when tapped with a piece of wood.

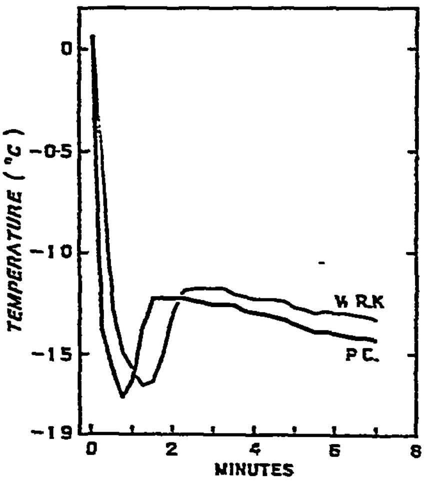

Fig. 1—Surface temperatures of the little fingers of W. R. K. and P. C. in brine at −1·9°C (circulation arrested by tourniquet, thermocouple covered by two layers of plaster).

Table I shows the results of similar experiments on three other men and six women. The procedure in these was identical with that in the experiments on W. R. K. and P. C. except that the fingers were left in the freezing mixture for only 4 minutes in most cases. In all except one case there was a sharp rise in temperature starting 45 seconds to 1 minute 45 seconds after the distal phalanx was immersed in brine, and the fingers were hard to the touch when removed. In one case the temperature fell irregularly, probably due to brine reaching the thermo-

* Surface temperature of this finger fell irregularly, probably owing to plaster allowing brine to reach thermojunction.

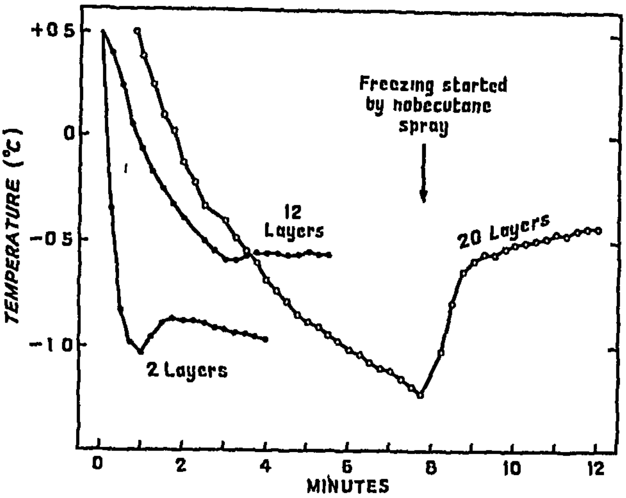

Fig 2—Temperature recorded from intracutaneous tracks in W R K 's little finger in brine at −1 9°C (circulation arrested by tourniquet, thermocouple and track covered by varying thicknesses of plaster)

junction, but this finger like the others appeared hard, white, and frozen when removed after 7 minutes The temperature in the other fingers rose to a plateau level usually at about −1 3°C

True Freezing-point of Skin

Fig 2 shows the results of three experiments on W R K which were representative of a number made on him and P C to try to determine the freezing-point of the skin more accurately The thermojunction was inserted into an intracutaneous track instead of lying on the surface, and was covered by varying thicknesses of plaster The finger was pre-cooled in ice and water to near 0°C in every case, and before the experiment with 20 layers of plaster was protected by a rubber finger-stall during pre-cooling in fresh water With 2 layers of plaster the temperature rose to 0 85°C when the finger started to freeze and then drifted downwards With 12 layers, the temperature rose to - 0 55°C, only slightly higher than the level to which it had fallen, and remained steady With 20 layers of plaster, the finger did not freeze spontaneously Freezing was, however, initiated by spraying it briefly with 'Nobecutane', and its temperature rose rapidly to −0 63°C and thereafter drifted upwards more slowly

Table II shows the results of a number of experiments of this type on W R K and P C using an intracutaneous or (in one experiment) a subcutaneous thermocouple in the tip of a needle In all cases when more than 6 layers of plaster were applied they indicated a freezing-point between −0 53 and −0 65°C, the results for P C being rather lower than those for W R K Soaking of W R K 's finger in fresh water for 30 minutes had little effect on its freezing-point The subcutaneous needle thermojunction used in one experiment on W R K gave a rather lower figure, probably because of stem error

Supercooling

In all the nine experiments recorded in table I the fingers, which were previously soaked in fresh water and ice, started to freeze spontaneously within 2 minutes of immersion However, there was always a rise in temperature when freezing started, showing that there had been some supercooling

P C 's little fingers froze spontaneously in brine at −1 9°C, even when they had been protected from fresh water during pre-cooling W R K 's fingers usually froze spontaneously in brine at −1 9°C when they had been previously soaked in fresh water, but failed to do so on one occasion, and failed to freeze on all five occasions *when they were immersed for 8–15 minutes in brine at* −1 9°C without preliminary soaking in fresh water Rubbing *a supercooled finger with wood or ice always* failed to initiate freezing, but spraying a small part of the skin with nobecutane started freezing on all of the ten occasions on which this was done, presumably by lowering the surface temperature of a small area of skin briefly to a level sufficient to overcome supercooling

There was never any difficulty in telling when freezing took place Apart from the sudden rise in temperature the skin suddenly became white in appearance and hard to the touch, with a clear line of demarcation from the non-frozen tissue There was often also a sudden sharp pain when freezing was started by the spray, though this was usually absent in spontaneous freezing

Freezing with Circulation Present

P C 's little finger was dipped into brine at −1 9°C without any pre-cooling and without a tourniquet The immersed skin froze hard after 4 minutes

Injury

The subjects whose fingers were frozen on a single occasion for up to 4 (or, in one case, 7) minutes experienced severe pain during rewarming, but the fingers looked normal and felt virtually normal the next day, and none subsequently became blistered However, the day after the distal phalanx of W R K 's right little finger was frozen for the fourth time, it became considerably

TABLE II—DETERMINATION OF THE FREEZING-POINT OF SKIN

Subject	Site of thermojunction	Layers of plaster over thermojunction	Whether finger was protected from fresh water during pre cooling	Start of freezing (min)	Temperature at onset of freezing (C)	Temperature after freezing (C)

* Finger soaked for 30 minutes in distilled water, then mopped dry, before thermojunction was inserted in track and plaster applied Procedure and track were otherwise identical with the previous experiment

painful and hyperæmic (fig 3) The hyperæmia and tenderness subsided during the next 4–5 days, but during the next 2 weeks most of the skin on it blistered off Lesser degrees of hyperæmia and blistering were observed after repeated freezing of W R K's left little finger and P C's little fingers The more severe degrees of hyperæmia and tenderness were produced only when a finger was frozen at a time when it was still slightly tender as a result of an earlier freeze, although the fingers were not frozen more often than once a day, or for more than 8 minutes at a time

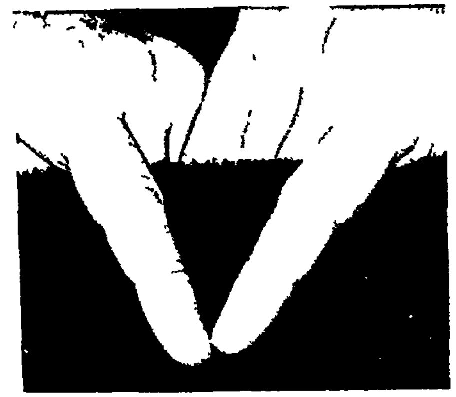

Fig 3—Appearance of W R K.'s right little finger after repeated short periods of freezing in brine at −1 9 C

To determine whether the damage was really a result of freezing, or whether it was a result of low temperature per se, an additional experiment was performed on W R K and subject 7

The terminal phalanx of the left little finger of each of them was supercooled in brine at −1 9°C, with circulation arrested, for 15 minutes, and in each case was still soft at the end of the experiment. On the same day the right little finger of each was also cooled in brine for 15 minutes the procedure being identical except that, after $3^{1}/_{2}$ minutes in the brine, freezing was started by a nobecutane spray The finger froze immediately, and at the end of the experiment, 11 minutes later, felt very hard Neither of subject 7's or W R K's little fingers had been frozen in the 3 weeks before this experiment The fingers were rewarmed by running water at 15°C over them at the end of the experiment, and care was taken not to subject them to trauma until they had been rewarmed.

The next day the fingers which had been supercooled looked and felt normal, while the fingers which had been frozen were tender and red and their skin temperatures were 4–8°C higher than those which had been supercooled The tenderness and difference in skin temperature decreased and had virtually disappeared 5 days later

Discussion

These results show that, contrary to general belief, human tissues can freeze at the temperature of freezing sea-water and that they can sustain injury as a result of being frozen at this temperature

Lewis and Love (1926) were unable to freeze human skin by placing it in contact with metal at temperatures above −2 2 C, and Lewis (1941) stated that " freezing of feet while immersed in sea water can hardly occur for the temperature of the water cannot fall below −1 9°C, its own freezing point " This apparent discrepancy with the present findings is probably due to the difference in method, large temperature gradients must exist in the skin when a metal bar is pressed on the skin of a warm limb, and even the most superficial part of the skin must be at a higher temperature than the bar Lewis and Love (1926) observed that supercooling of skin was common and could be reduced by soaking the skin in fresh water The present experiments confirm this, dry fingers sometimes supercooled and sometimes froze in brine at −1 9°C, but they almost always froze when they had been soaked in fresh water beforehand They failed to do so on only one occasion after such preliminary immersion

In the experiments with surface thermocouples covered by two layers of plaster their temperature rose to −1– −1 76°C when the skin froze Since the thermocouples were between the skin and the brine, the temperature they recorded must have been below that of the skin, and the true freezing point must have been higher The experiments using intracutaneous tracks and 6–12 layers of plaster, on the other hand (table II, fig 2) gave stable temperatures for some minutes in the region −0 6°C when freezing started When more layers of plaster were applied the temperature failed to stabilise after the sudden rise when freezing started, and continued to drift upwards, probably because the junction lay in a region between the freezing tissue and the warm, non-immersed part of the finger The position of the breaks in these curves also, however, indicates a true freezing-point of about −0 6°C

No previous determination of the true freezing-point of human skin appears to have been made, Lewis and Love (1926) were clear that their method determined the temperature at which supercooling was overcome rather than the true freezing-point, which must be higher The freezing-point of mammalian tissues has been reported to be −2 2°C (R B Lewis 1951), but Lovelock and Smith (1956) and Appelboom et al (1958) have found it to be about −0 56°C This is approximately the freezing-point of blood, which may vary from −0 51 to 0 61°C with varying degrees of hydration of the body (Margaria 1930) It is a familiar observation that human skin becomes wrinkled when soaked in fresh water, and must therefore absorb water which will raise its freezing-point somewhat Such absorption of water by the surface layers may reduce the power of skin to supercool (Lewis and Love 1926, table II), but since only a trivial elevation of freezing-point, within the limit of experimental error, could be obtained by soaking for 25 minutes (table II), the freezing-point at least of the deeper layers of the skin cannot have been greatly altered by these means

It might be argued that cold vasodilatation should normally protect the extremities from freezing in brine at −1 9°C However, although cold vasodilatation always appears eventually in the fingers of even chilled men when the fingers are cooled to 0°C, the dilatation always takes several minutes, and often 30 minutes or more, to start (Keatinge 1957) The extremities can clearly freeze solid long before this time, and freezing of P C's little finger was observed 4 minutes after immersion in brine at −1 9°C even without previous cooling and with the circulation intact

Although freezing at −1 9 C for periods of 4–7 minutes did not give rise to any significant after-effects, freezing for $11^{1}/_{2}$ minutes caused pain and hyperæmia for several days Repeated freezing for shorter periods at intervals of a day or two caused pain, hyperæmia, and blistering of the skin Lewis and Love (1926) reported that freezing of human skin caused more injury than supercooling, but Smith (1954) reported that supercooling, as well as freezing, could cause necrosis of the extremities of hamsters. Since supercooling of fingers in these experiments did not cause the after-effects produced by freezing them at the same temperature and for the same time, and since on previous occasions fingers have been kept at 0°C for much longer without injury (Keatinge 1957), the change observed in these fingers must have been due to freezing. The results obtained by Smith (1954) in hamsters suggest that the injury would have been greatly increased if the tissue had been subjected to trauma while frozen; trauma to frozen fingers was carefully avoided in the present experiments.

The greater injury caused by repeated freezing in these experiments contrasts with the report of Fuhrman (1957) that a brief freeze of the legs of rats (1 second at −25°C) decreased the damage caused by subsequent freezing 2 days later. The difference in the duration and temperature of freezing in this worker's experiments, and the fact that rats were used, may account for the apparent contrast with the present results.

The freezing-point of sea-water in the Arctic Ocean is variable, particularly near the mouths of Arctic rivers, but in the region of the Norwegian sea, as in most of the ocean, it is about −1·9°C (Sverdrup et al. 1942). Many immersion injuries were suffered by men in ships sunk in this area in the late war (Ungley 1949, McCance et al. 1956). The present results show that frostbite may contribute to such injuries and is particularly likely if the skin is wet before immersion. It is clearly important to provide sufficient protection to keep the skin temperature 1°C or more above water-temperature when immersion in freezing sea-water is unavoidable.

Summary

Human fingers cooled to −1·9°C, the freezing-point of sea-water, usually froze. They almost invariably did so when they had been soaked in fresh water and ice beforehand.

The true freezing-point of human fingers was found to be between −0·53 and −0·65°C.

Freezing in brine at −1·9°C for 4–7 minutes, without trauma in the frozen state, caused no significant injury. However, freezing for 11½ minutes or repeated freezing for shorter periods caused hyperæmia and tenderness lasting several days and, in the case of repeated freezing, blistering of the skin. No ill-effects were produced by supercooling fingers to the same temperature for the same time.

Earlier statements that human tissues cannot freeze in sea-water appear to have been based on indirect evidence.

A WELL-RECOGNISED danger of ulcerative colitis is considerable depletion of fluid and electrolytes from excessive gastrointestinal loss. This may arise either because of severe diarrhœa in the intact patient undergoing medical treatment, or because of profuse postoperative discharge from the ileostomy. The magnitude of the loss in each of these circumstances has been specially studied by Lubran and McAllen (1951) and Crawford and Brooke (1957). These workers have stressed particularly the risk of potassium deficiency in the medically treated colitis patient who still has a functioning large intestine, and of sodium depletion after an ileostomy has been established. The investigations which we here report were undertaken as an amplification of this previous work, but our findings, though largely confirmatory, differ in certain important respects.

Material and Methods

Fæcal loss of fluid, sodium, potassium, and, in certain circumstances, nitrogen was estimated in nine patients awaiting operation for ulcerative colitis, and in sixteen patients after operation, which in all cases took the form of a one-stage ileostomy with total proctocolectomy. Similar investigations were made in two cases with ileostomies established for 12 months. Three of the preoperative patients and the two patients with established ileostomies were given an ordinary ward diet, but six had extensive balance studies, being given various quantities of sodium and potassium with a fixed intake of 3000 ml. water daily.

In most of the postoperative cases the fluid and electrolytes given accorded with the needs of ordinary postoperative management. Intravenous infusion was continued as a rule for only 24–36 hours. Fluids were given by mouth immediately after operation, and were gradually increased in amount from 30 ml. hourly until, by the 4th or 5th postoperative day, a light diet was taken, and by the 8th–12th days the diet was fairly full. In three patients, however, a fixed intake of 3000 ml. of fluid daily, together with sodium 300 mEq. and potassium 87 mEq., was maintained throughout the period of investigation—i.e., up to the 12th postoperative day.

Of the sixteen patients studied after operation all except one recovered without complication. Six had steroid therapy during and after operation (dosage 100 mg. t.d.s. for 2 days, 100 mg. b.d. for 2 days, and then reduction of the total dose by 50 mg. daily to a maintenance dose of 50 mg. daily, which was continued until the end of the study period). Of these six patients, five recovered uneventfully, but in one peritonitis necessitated further operation to drain the abdomen. After this she progressed satisfactorily, although profuse ileostomy diarrhœa was associated with the intraperitoneal sepsis.

Collection of Specimens and Chemical Analysis

24-hour collections of urine and fæces or ileostomy fluid were made. Each specimen was measured for volume, and analysed for sodium, potassium, and nitrogen content.

Volume of fæces or ileostomy fluid.—The specimen was transferred to a graduated volumetric flask, using a weighed amount of water, and filled to the mark with a weighed amount of water. (Thus volume of specimen = volume of flask − weight of water added.) The contents of the flask were then homogenised. If frothing appeared, a few drops of caprylic alcohol were added.

Sodium and potassium estimations.—To 10 ml. of the homogenised "fluid" in a conical flask concentrated nitric acid 2 ml. (analytical reagent) was added. (The acid had previously been freed from all lower oxides of nitrogen by boiling with $^{1}/_{4}$ of its volume of water until the brown discoloration disappeared.) With a glass bubble in the top of the flask, the mixture was brought to the boil for a minute or two. After cooling, the digest was transferred to a 50 ml. graduated flask. The volume was made up to the mark with distilled water, and the contents were mixed thoroughly. The mixture was filtered, and the filtrate was diluted similarly with water. The sodium and potassium contents were measured in an 'Eel' flame-photometer.

Nitrogen estimation.—The macro-Kjeldahl method was used. 10 ml. of homogenised fæces or ileostomy fluid or 5 ml. of urine was digested with concentrated sulphuric acid 20 ml. and copper sulphate 0·2 g. in a 250 ml. Kjeldahl flask. Heating was continued for 1 hour after the colour had cleared. After cooling, distilled water 80 ml. was added, followed by caustic soda 40% in excess (phenolphthalein indicator). The ammonia was distilled over into 0·2 *N* sulphuric acid 20 ml., containing methyl-red as indicator. When the volume of the liquid in the Kjeldahl flask had been reduced by half, distillation was discontinued. The excess acid in the receiving flask was titrated with 0·1 *N* sodium hydroxide, and the nitrogen content was then estimated.

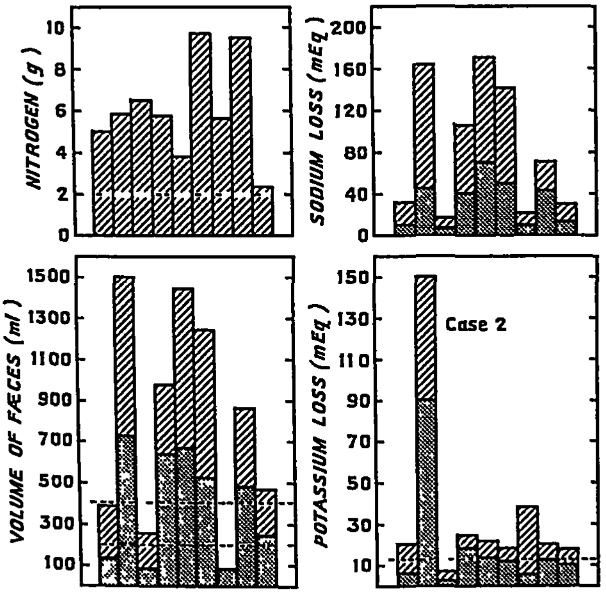

Fig. 1—Daily minimum and maximum fæcal volumes and sodium, potassium, and nitrogen loss in nine colitis patients before operation.

Results

BEFORE OPERATION

Volume of fæces.—Fig. 1 shows the minimum and maximum fæcal volumes in the nine patients investigated before operation. The normal maximal fæcal volume of 400 ml. was exceeded in all except two. In three patients the fluid intake was increased from 1500 ml. to 3000 ml. per day, without increase in fæcal volume. But when the fluid and sodium intakes were increased simultaneously the fæcal volume rose rapidly.

Sodium excretion.—Accepting the normal fæcal loss of sodium as 2–5 mEq. per day, the results in all the patients studied (fig. 1) show that the excretion was greatly in excess of normal. Although the sodium loss varied between 9 and 170 mEq. per day, in no patient was this sufficient to produce the clinical syndrome of sodium depletion. In six patients (cases 4–9), in whom the fluid intake was 3000 ml. daily, the sodium intake was known. The table shows the effect of a higher sodium intake (cases 7–9) on the fæcal and urinary volumes and the fæcal and urinary excretion of sodium. (These data were compiled after an initial period of 6 days for equilibration.)

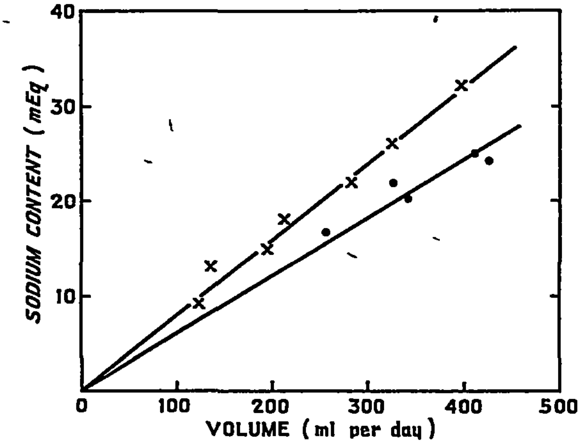

Fig. 2—Sodium loss in two of the seven patients in whom sodium excretion was proportional to fæcal volume.

When increased quantities of sodium were taken by mouth both the sodium content and volume of the fæces increased, this may indicate a defective absorptive capacity of the large bowel for sodium. In seven of the nine patients investigated the sodium excretion was proportional to the fæcal volume (fig. 2). Though the sodium content of the fæces was remarkably constant in any one patient despite considerable fluctuations in volume, the amount of sodium varied from patient to patient.

Potassium excretion.—As fig. 1 shows, the loss of potassium exceeded the normally accepted value of 6–12 mEq. per day in all except one patient. With this exception the potassium loss was relatively little, being only 2–3 times the average daily normal. In this patient (case 2, column 2) the loss of potassium varied between 90 and 167 mEq. per day, but despite this (and without potassium supplements by mouth) the serum-potassium level remained within normal limits. In five patients the

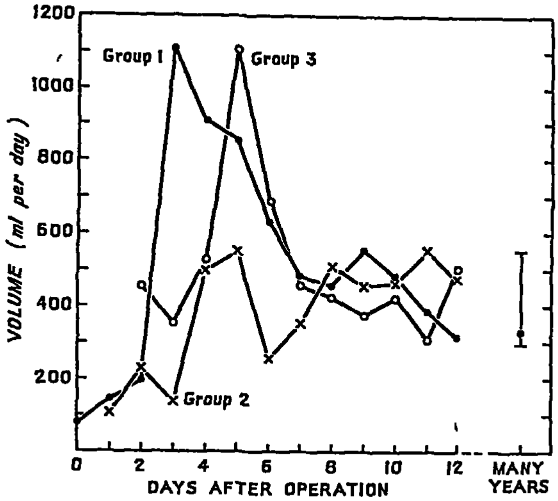

Fig 3—Volume of ileostomy discharge in the 3 groups of patients not treated with steroids

fæcal potassium loss was related directly to volume, but, as with the sodium loss, this was not applicable to the group as a whole, neither did potassium loss and fæcal volume necessarily correlate in those patients in whom sodium loss correlated with the volume of fluid excreted

Nitrogen excretion —In seven patients in whom the fæcal nitrogen loss was studied, the normal value of 2 g per day was exceeded This caused the fæcal nitrogen loss to fluctuate between 20% and 30% of the daily intake of protein, compared with the normal of 10% Four of the six patients subjected to balance studies (daily nitrogen intake 9 4–12 g) were in negative balance—a result in keeping with their progressive weight loss

AFTER OPERATION

Uncomplicated Cases not having Steroids

The eleven patients have been divided into 3 groups depending on the time of onset of ileostomy discharge after operation In group 1 (two patients) the discharge started on the day of operation, in group 2 (four patients) it began on the 1st day after operation, and in group 3 (five patients) it was delayed until the 2nd day

Volume of ileostomy discharge —The average volume of ileostomy discharge in the 3 groups is shown in fig 3 After the ileostomy began to function the volume of discharge increased rapidly until, between the 3rd and 5th days, a maximum was reached The volume then diminished until, by the end of the 1st week, the volumes excreted were within the range of the established ileostomy —i e , between 200 and 500 ml per day After the period of greatest excretion the consistence of the ileostomy discharge rapidly changed until, by the end of the first 10 days, it was porridge-like, resembling the fæces from a long-established ileostomy In only two patients was the volume of discharge more than 2000 ml per day, and this abnormal amount was passed once only in each case

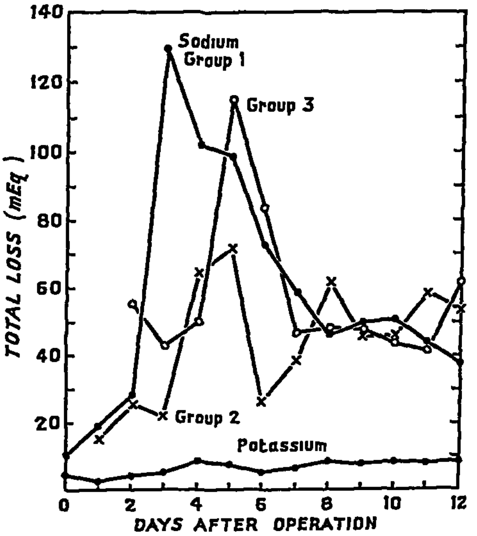

Fig 4—Average total sodium and potassium loss after operation in the patients not treated with steroids

Sodium —The daily average sodium excretion via the ileostomy was calculated for each of the 3 groups The total loss of sodium did not exceed 130 mEq per day in any patient, and the greatest loss of sodium corresponded to the greatest discharge from the ileostomy In all patients within 1 week of operation the daily sodium loss fell to 40–60 mEq , a rate of excretion such as is found with long-established ileostomy Fig 4 shows the average daily loss of sodium for each group Comparison with fig 3 suggests that sodium and fluid loss are closely related, indeed these two factors are directly proportional, as is shown in fig 5, calculation of their correlation coefficient exceeding the 0 1% level of significance Thus the sodium content of the ileostomy fluid seemed to remain constant at 120 mEq per litre when volumes within the normally accepted range were excreted

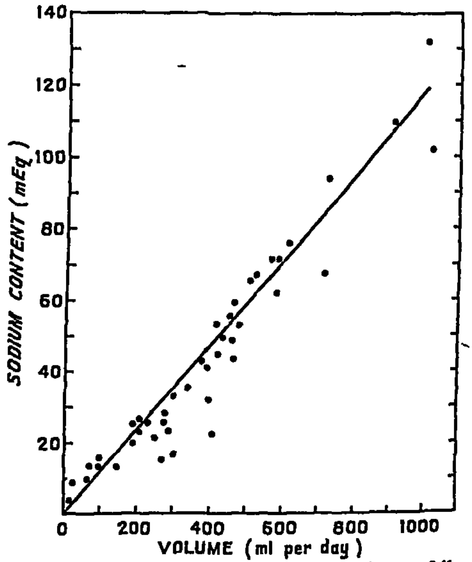

Fig 5—Relation between sodium content and volume of ileostomy fluid in patients not treated with steroids

Potassium —The total potassium loss varied between 1 and 12 mEq daily But whereas the correlation between sodium content and fluid excreted satisfies all statistical inquiry, this was not true of potassium, the loss of which varied from day to day within very narrow limits

Nitrogen —Nitrogen excretion from the ileostomy was negligible in the seven patients in whom it was measured The amount varied between 0 4 and 1 8 g daily, these values representing the minimum and maximum values over a period of 15 days' observation The loss of nitrogen is thus not important in the practical management of ileostomy patients

Cases treated with Cortisone

The following data relate only to the postoperative period Cortisone seemed to exert an influence on both

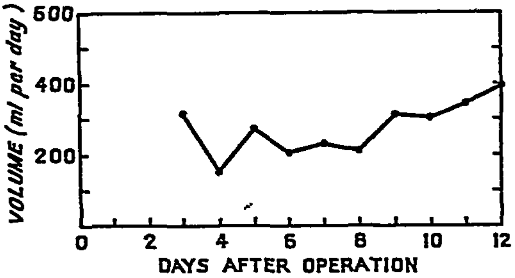

Fig 6—Average volume of ileostomy discharge in five cortisone-treated patients

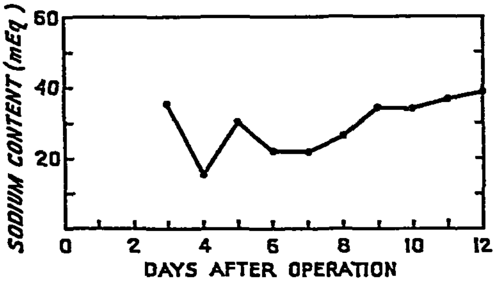

Fig 7—Average total daily sodium loss in five cortisone-treated patients

the quantity of the ileostomy discharge and the concentration of its constituents

Volume—The time-interval between operation and the onset of ileostomy function was uniformly delayed until the 3rd postoperative day in patients treated with cortisone. Fig 6 shows that, whilst the volume of the ileostomy discharge ultimately reached that typical of the patients who did not have steroids, no peak of excretion appeared in the early postoperative period

Sodium excretion—The total daily sodium excretion in the five patients investigated is shown in fig 7 The greatest total loss of sodium in a single case in this group was 87 mEq per day, but in the whole group, in which 100 observations were made, only 10 values exceeded 50 mEq per day As with fluid excretion there was no peak of sodium excretion The sodium content of the discharge was 109 mEq per litre as compared with 120 mEq per litre in the patients not treated with steroids—a statistically significant difference.

Potassium—The total potassium loss via the ileostomy varied between 3 and 9 mEq per day, these values being similar to those observed in the cases not treated with cortisone The total potassium loss increased with the volume of the discharge and then remained relatively constant.

Nitrogen—Loss of nitrogen from the ileostomy was specifically investigated in one patient only, but, since values between 0 5 and 1 7 g per day were found, the loss of nitrogen is probably similar to that previously observed in the patients not treated with steroids

Ileal Dysfunction Associated with Peritonitis in a Patient having Steroids

In one patient ileal dysfunction was apparently due to intra-abdominal sepsis When the abdomen was re-explored on the 4th postoperative day general peritonitis was found and the abdomen was drained, after a difficult convalescence the patient recovered The total fluid, sodium, and potassium loss in this case are recorded in fig 8 This shows the greatly increased volume of fluid excreted throughout the period of observation, and the high loss of sodium and potassium amounting to as much as 300 mEq of sodium and 60 mEq of potassium daily Whilst the sodium content fell below the normal of 120 mEq per litre, the potassium content was abnormally high In such circumstances there is danger of both sodium and potassium depletion, and intravenous supplements of these cations were required throughout the period of investigation

The changes in the ileostomy discharge in this case seem to us characteristic. Indeed another patient in whom peritonitis developed on the 18th postoperative day had similar changes in the ileostomy discharge, although the chemical data were insufficient for us to report this case in detail

Discharge from the Long-established Ileostomy

In two patients whose ileostomy discharge was investigated some time after the fistula was established the results agree with those already described during the 2nd week of function in patients not having steroids

In both our patients the total daily volume of discharge fluctuated between 300 and 500 ml The sodium content agreed closely with the previous findings, being 120 mEq per litre The potassium loss ranged from 3 to 4 8 mEq per day, and even in the same patient the content varied

The nitrogen loss differed little between the patients with recently established and long-established ileostomies, values between 0 5 and 2 g daily being observed in the latter

Discussion

The Preoperative Patient

Contrary to the reports of Gardner et al (1949) and Lubran and McAllen (1951) potassium deficiency was not a problem in the preoperative management of the seven patients we studied in detail (neither was lack of potassium a notable feature in ninety-eight additional cases which came under our care for surgical treatment during the past 4½ years, being evident in only two of these patients) This is perhaps surprising in view of the earlier findings of potassium depletion in four out of thirty consecutive cases of colitis observed by Lubran and McAllen (1951) But in our cases the fæcal volumes were relatively small, never being greater than 1500 ml per day, whereas

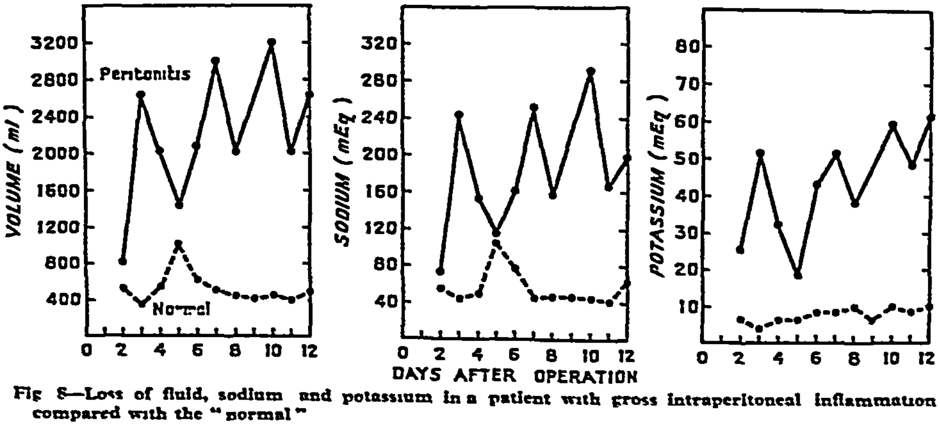

Fig 8—Loss of fluid, sodium and potassium in a patient with gross intraperitoneal inflammation compared with the "normal"

in Lubran and McAllen's patients the daily loss of fluid per rectum was as much as 2500 ml Welch et al (1937) and Lubran and McAllen (1951) found that electrolyte loss was determined by the fæcal volume Welch et al found that the sodium and potassium loss in colitis patients was (jointly) equivalent to a 70% isotonic solution, Lubran and McAllen thought the fæcal fluid was isotonic with plasma

Our findings suggest that the cation equivalent of the fæces varies, ranging from hypotonic to isotonic in different patients and from day to day, depending on fæcal bulk Lubran and McAllen (1951) found that the loss of sodium and potassium was directly proportional to the volume of fluid excreted But in our experience, though the loss of cations may be proportional to the volume, the observations in one patient are not applicable to the next, neither is a proportional potassium loss necessarily found in patients with a fixed relation for sodium

Our findings suggest also that in colitis the inflamed colon is unable to absorb sodium, for when increased amounts of sodium were given by mouth increased quantities were lost in the stools, which were of greater volume

In general the loss of nitrogen in the colitis patient is higher than normal, as shown by the increased fæcal loss The greatest fæcal loss of nitrogen in any of the seven preoperative patients we studied was 10 g per day (roughly equivalent to 60 g of protein), exceeding greatly the normal of 2 g per day Miller et al (1949) alleged that a fæcal loss of up to 100 g of protein daily might arise in severe cases of colitis, and therefore favoured primary colectomy instead of simple ileostomy, leaving the colon intact Whilst we cannot confirm their estimations, we think that a sustained daily loss of 60 g of protein could be seriously detrimental, particularly postoperatively, when intake might be much reduced

The Ileostomy Patient

Our findings regarding sodium excretion from the recently formed ileostomy are notably at variance with those of Crawford and Brooke (1957) These workers claimed that immediately after the establishment of an ileostomy the fæcal sodium content was at first very high, amounting to 200–400 mEq per litre, and that as the fæces gradually thickened the sodium content fell to the same level as is found in patients with long-established ileostomies—namely, about 150 mEq per litre But if this initial value were added to the potassium loss of 10 mEq per litre which they found, a hypertonic fluid would be excreted via the recently established ileostomy This would be somewhat remarkable Apart from conflicting with our findings, it conflicts also with the findings of Lans et al (1952), who estimated, by aspirating the ileal contents through nasal or oral tubes, that the sodium content was about 121 mEq per litre (range 88–146 mEq) and the potassium content 9 6 mEq per litre (range 4 8–13 6 mEq), which implies that the ileostomy discharge should be isotonic or slightly hypotonic relative to plasma

Crawford and Brooke (1958) admitted later that the high sodium content they had found in the ileostomy fluid immediately after operation was difficult to understand After a careful check on their methods they suggested a possible explanation All their patients were given sodium-chloride tablets by mouth after operation, and some of these might not have dissolved completely in the alimentary tract, thus being passed semidigested and dissolving later in the storage cans, thereby raising the sodium content

We found that in most patients ileostomy function began on the 2nd day after operation, that the greatest fæcal volume was excreted during the 1st week, and that the volume of discharge was then in most cases equivalent to the accepted normal for the established stoma The maximum volume was seldom greater than 1000 ml per day in the absence of complications, and we believe that if greater volumes than this are excreted the ileostomy is malfunctioning, either because of mechanical difficulties, such as obstruction, or because of inflammatory changes close to the bowel, as in peritonitis

In all our patients the sodium loss seemed to be directly proportional to the volume excreted, and in the average ileostomy patient *the sodium content was 120 mEq per litre regardless of the fæcal volume* Thus for practical purposes there is no difference in the concentration of sodium between the recent and long-established ileostomy Whilst sodium loss was directly related to the volume of ileostomy fluid, the loss of potassium varied between different patients and in the same patient from day to day, but under normal circumstances it never exceeded 11 mEq per day, which is considerably less than the normal daily intake of 50–200 mEq potassium (Thompson and King 1957) Thus in the ordinary patient after ileostomy the sodium and potassium loss is not a serious hazard, the volumes excreted are normally small, and the cation contents are together equivalent to a fluid isotonic as compared with plasma

In the practical management of uncomplicated cases the potassium loss may be ignored completely, and the sodium and fluid loss can be replaced accurately by normal saline (156 mEq of sodium per litre) intravenously in amounts equal to the volume of ileostomy fluid excreted But when some condition causes massive increase in the ileostomy discharge, the loss of water, sodium, and potassium may become critical In our case in which ileal dysfunction was due to peritonitis, the volume of fluid was sometimes as high as 3 litres per day, and never less than 2 litres per day for 14 days during the recovery period Associated with the high fluid output the total loss of sodium and potassium was considerable—between 260 and 300 mEq per day for sodium and between 20 and 60 mEq per day for potassium This single case suggests that the small intestine makes some attempt to conserve sodium, for when there was profuse ileostomy diarrhœa the fæcal sodium content was reduced to 110 mEq per litre compared with the normal of 120 mEq per litre in uncomplicated cases

The Effect of Cortisone

Many patients with ulcerative colitis have had steroid therapy before surgery, and they therefore need it during and after operation to guard against adrenal failure Such hormone administration affects the ileostomy discharge

In 1958 Brooke reported the effect of cortisone on the ileostomy in three patients who had had this drug before and immediately after the stoma was established He found that cortisone reduced the volume of fluid excreted via both the kidney and the stoma, that the sodium content was lowered, and that the potassium content was raised In general these findings are confirmed by our present study, the sodium/potassium ratio of the ileostomy fluid (normally 11–18 in patients with a recent ileostomy) being 6 in the cortisone-treated patients This reduction is due to diminution of the sodium content and increase of the potassium content of the fæces That this is not due to chance is shown by the effect of cortisone given temporarily to a patient with an adrenal crisis (fig 9), in this case the sodium/potassium ratio fell from 16 to 2 after cortisone was given, and rose rapidly again when cortisone was discontinued

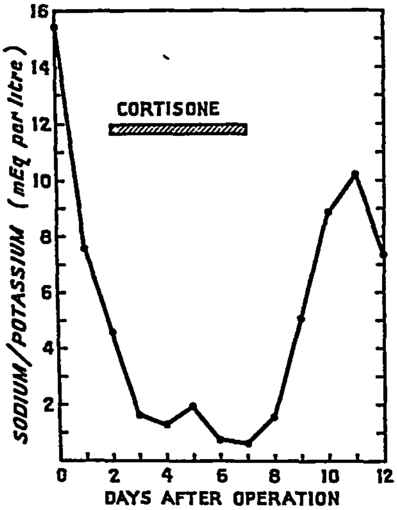

Fig 9—Effect of cortisone on the sodium/potassium ratio of the ileostomy discharge in a patient with adrenal failure

Like Brooke (1958) we found that, in general, the volume of ileostomy fluid is lowered in the cortisone-treated patient Brooke suggested that cortisone might be tried in those patients who normally have a watery ileostomy discharge in the absence of mechanical disturbances of the stoma But in the one patient we studied with this state of affairs, the volume of the ileostomy fluid did not decrease significantly over a period of 14 days' cortisone therapy Thus steroids are not always effective in checking such excessive ileostomy action

Summary

The fluid, electrolyte, and nitrogen loss was studied in nine patients with ulcerative colitis before operation and in sixteen patients after operation

Before operation the fæcal loss in all patients exceeded the normal, although the loss of potassium was not as high as was expected from the results of previous investigations

After operation the greatest excretory activity when the volume of discharge rose to as much as 1500 ml was during the 1st week The sodium content of the discharge was 120 mEq per litre, but the potassium content varied Nitrogen loss varied between 0 4 and 1 8 g daily

In patients treated with cortisone postoperatively the volume of the discharge gradually increased to normal values, without a peak The sodium content was 109 mEq per litre, and relatively large amounts of potassium were excreted

In a patient with peritonitis the loss both of fluid and cations was increased considerably, necessitating continuous intravenous supplements throughout the period studied

We wish to acknowledge with thanks a helpful exchange of ideas with Dr N F Coghill, Dr M. Lubran, and Mr B N Brooke before we started this study We are also much indebted to Miss F E Briggs, B.SC, dietitian, and to Sister Margaret Thwaites, Sister E L Moxon, and Sister Joan Womersley and their nurses for much assistance with this investigation

ARTERIAL PERFUSION IN THE LOWER LIMB AS AN AID TO VASCULAR SURGERY

F Ashton

PROFESSOR OF SURGERY IN THE UNIVERSITY OF LONDON
AT CHARING CROSS HOSPITAL MEDICAL SCHOOL, W C 2

From the Department of Surgery, University of Birmingham

The value of restorative procedures in the treatment of obstructive disease of the aortic bifurcation and iliac, femoral, and popliteal arteries is well established These procedures may take the form of restoring the arterial lumen (disobliteration) or a bypass of the obstruction with arterial homografts or synthetic tubes

Selection of Patients for Restorative Surgery

There are two main groups of patients (*a*) those in whom loss of the limb is inevitable in the immediate future, because of gangrene or intolerable rest pain, and (*b*) those in whom the clinical features, claudication, or ulceration are not so clamant, who can carry on even if only with reduced activity This second group includes some who find restriction of activity intolerable or impossible owing to financial or business reasons, and who should, for the purpose of treatment, be classed with group (*a*)

When assessing each patient for the advisability of restorative surgery the morbidity, mortality, and likely success of the operation must be balanced against the degree of local disability and the general state of the patient For patients in group (*a*) there is nothing to be lost by an attempt at some restorative procedure, whereas in group (*b*) the problem is more difficult, for gangrene may be precipitated by an unsuccessful operation When advising patients in this group the position must be put to them squarely without minimising the risks Cardiac, cerebral, or other disease in an acute phase contraindicates any lengthy operation involving a certain amount of hæmorrhage A past history of coronary thrombosis is not necessarily a contraindication, though ironically enough a successful operation in a patient with valvular heart-disease may precipitate cardiac failure by reason of the increased cardiac output required

Arteriography as an aid to diagnosis and selection is indispensable without it the surgical alternatives are sympathectomy (so capricious in its effects) and amputation Arteriography reveals the precise site and extent of any arterial obstruction, whether the lesion is multiple, the degree of the collateral circulation, and the patency of the smaller vessels in the lower leg and foot Restorative operations are only suited to those cases where the principal cause for the ischæmia is in the main vessels and where the distal part of the popliteal artery is sufficiently patent to enable a satisfactory anastomosis of a bypass graft to be effected In most cases similar disease is present in the smaller vessels, and in some the poor filling of arteries with the contrast medium ('Hypaque') below the knee may be such as to discourage an attack on the main vessel Table I shows how 44 patients seen in a period of six months were assessed after arteriography

Measures to Avert Failure in Grafting

In the operative and immediate postoperative period an artery graft will fail if the blood within it clots Such clotting is the result of poor linear flow Assuming that the

TABLE I—ANALYSIS OF TREATMENT OF 44 PATIENTS ADMITTED WITH PERIPHERAL VASCULAR DISEASE OF THE LEGS OVER A SIX-MONTH PERIOD

anastomosis (end-to-side) between each end of the graft and patient's artery is technically satisfactory and therefore fully patent, the cause of failure is to be looked for in the blood-flow in the femoral artery above and the popliteal artery below

1 If there is narrowing of the femoral artery or yet another obstruction above, the impelling force or head of pressure of blood entering the graft is insufficient Because of this danger it has become the practice over the past three years to join the upper end of the graft to the common femoral or external iliac artery, and *not* to the femoral artery below the origin of the profunda femoris Thus much longer lengths of graft material (homografts) are being used than before in femoropopliteal obstructions The head of pressure may be further reduced by operative and postoperative hypotension, measures against which include adequate blood replacement By opening up collateral channels, sympathectomy will also rob the graft of its blood-flow

2 Below the distal anastomosis there must be sufficient lumen in the popliteal artery and its branches to admit and pass on towards the foot the full flow of blood from the graft As evidence of this we have come to rely upon a good "bleed back" when the popliteal artery is opened But failure can still occur because, as arteriography often shows, the patency of the posterior and anterior tibial arteries is imperfect Also any lumen is further reduced by clotting during the period of limb ischæmia that is necessary while the graft is being sewn into position Prolonged ischæmia causes muscle damage and œdema, and this in turn will obstruct small or partially blocked vessels Heparin can be administered systemically, but usually it is injected locally as heparin saline down the popliteal artery during grafting Owing to difficult situations caused by hæmorrhage and hæmatoma formation, systemic anticoagulation is not continued after the operation

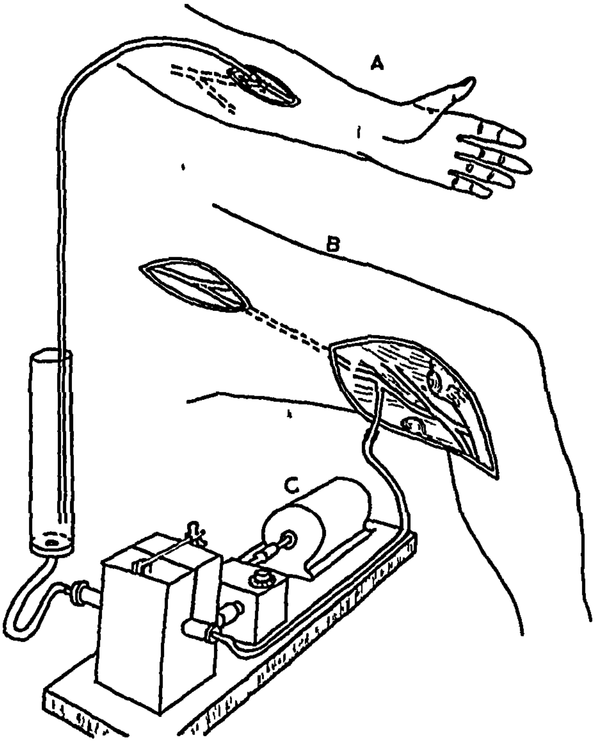

Fig 1—Cannulations made and apparatus

A shows a vein in the antecubital fossa cannulated centripetally Blood is drained into the cylindrical reservoir

B shows the vessels exposed in leg, with the upper graft anastomosed to the common femoral artery (in the upper incision) The interrupted double line represents the graft lying beneath the fascia in the thigh *The lower graft has been anastomosed to the popliteal artery* (lower incision), and the side branch has been cannulated to receive blood from the 'Sigma' pump (C) It only remains to anastomose the two free ends of the grafts

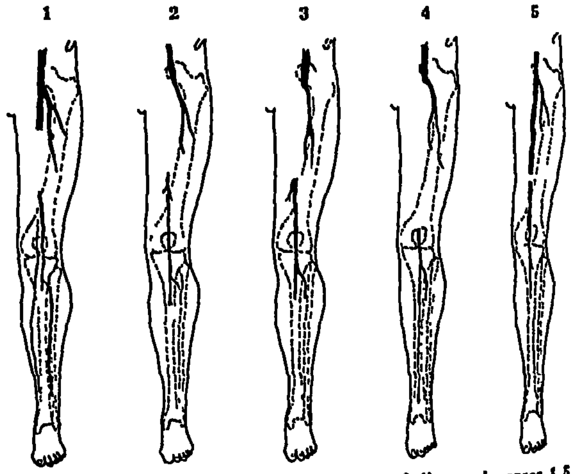

Fig 2—Result of arteriography and extent of disease in cases 1 5 whose legs were perfused

The disease in cases 1 and 5 was on the right side, but for the purpose of comparison it is shown as if it were in the left leg X rays *of the lower leg and ankle were not taken in cases 2 and 3* The distal vessels are most severely affected in case 5 See table II

Trial

It was thought that if the circulation through the smaller distal vessels of the limb could be maintained artificially while the main artery was occluded during the insertion of the graft, the chances of a successful outcome might be greater

With perfusion, restorative operations might be extended to cases shown on arteriography to have such severe peripheral disease, which otherwise would be classed as unsuitable

Methods

Principle

An intravenous dose of heparin is given to prevent clotting A vein in the antecubital fossa is cannulated, and from this venous blood is conducted into a reservoir (fig 1) Blood is pumped from here into the artery below the occlusion The venous blood used for perfusion is about 60% saturated with oxygen, but the saturation may be increased by heating the limb Copious bleeding is ensured by a sphygmomanometer cuff placed around the arm, inflated to 60 mm Hg Venous return from the perfused limb is via the natural channel—the leg veins

Apparatus

The venous cannula is flexible, consisting of a rigid nylon tube which is inserted into the vein, connected to a solid turned nylon adaptor by a flexible, clear polyvinyl-chloride (P V C.) tube (Drew et al 1957) The diameter may be 4–6 mm The adaptor is inserted into a $^{1}/_{4}$ in (6 0 mm) internal-diameter P V C hose which leads to a reservoir The reservoir is a cylinder of rigid P V C and is of 1$^{1}/_{2}$ in (37 0 mm) internal diameter

TABLE II—CLINICAL FEATURES, OPERATION DETAILS, AND RESULTS OF PERFUSION IN 6 CASES OF ARTERY-GRAFTING

F = femoral Pop = popliteal P T = posterior tibial D P = dorsalis pedis
The return of pulses after operation is sometimes delayed for several days Absent distal pulses are quite compatible with relief of symptoms (case 5)

From the bottom of the reservoir a $^1/_4$ in (6 0 mm) P V C. hose leads to a Sigma or deBakey type pump, and a similar hose connects the pump to the arterial cannula which, like the venous one, is flexible

Technique of Bypass Grafting from Common Femoral to Popliteal Artery

The clotting-time of the blood is estimated by the method of Dale and Laidlaw (1911) The anæsthetised patient lies supine on the operating-table with diseased leg abducted and externally rotated at the hip and flexed at the knee The popliteal artery is approached through an incision on the medial aspect of the leg The insertion of gracilis, sartorius, and semitendinosus is divided The medial head of the gastrocnemius, and if necessary that part of the soleus origin which is attached to the soleal line on the tibia, are divided and displaced backwards

The patent vessel below the block is incised, and any atheromatous deposits are removed until a free " bleed-back " from the distal end of the artery is observed

The assistant meanwhile reconstitutes two freeze-dried homografts of such combined length as to span the distance from the common femoral to the popliteal artery Each consists of the common, external iliac, and upper femoral arteries All the side branches are tied off or sutured except the internal iliac branch, which is left about 1 in (2 5 cm) long The surgeon then anastomoses the end of one of the grafts to the opening in the popliteal artery While this anastomosis is being made, the patient is heparinised with heparin 1 mg per kg body-weight The assistant cannulates the basilic or median cubital vein centripetally The apparatus is charged with blood from the patient until the arterial cannula is filled, and the arterial cannula is inserted into the internal iliac branch of the graft and tied in The free end of the graft is temporarily closed by a bulldog clip and the perfusion started The surgeon is now free to continue the operation secure in the knowledge that the patency of the lower graft, the leg vessels, and the anastomosis between them is assured by a stream of heparinised blood

A separate vertical incision in the groin exposes the common femoral artery and its two terminal branches—the profunda and superficial femoral arteries If necessary, the external iliac artery can be exposed through an additional wound The common femoral artery is clamped, and the natural blood-supply to the limb is now cut off except for that entering it by the cruciate anastomosis via the buttock, and until the completion of the operation the nutrition of and the blood-flow in the limb depend almost entirely on perfused blood This period may be as long as an hour according to circumstances Without perfusion the limb would be almost totally ischæmic, during this time

An incision is made in the common femoral artery, and here again extensive atheromatous deposits may need to be removed An end of the second graft is anastomosed to this incision, taking as much time as is necessary to ensure a perfect suture line The lower end of the upper graft is passed down the thigh under the fascia to emerge in the lower wound Redundant graft is excised, and the two free ends of the grafts are joined (fig 1) The perfusion is stopped The arterial cannula is removed from the side branch of the lower graft, which is temporarily clamped The bulldog clip on the upper end of the lower graft is released and reapplied just below the side branch The main vessel is momentarily released, and a jet of blood washes out any clot in the upper graft The side branch is tied off and the bulldog clip removed Finally the upper clamp is taken away, thus re-establishing the circulation The wound is closed by replacing muscle origins and suturing the deep fascia with catgut No drains are used The clotting-time is measured and sufficient protamine sulphate given to restore it to normal

Results

The perfusion technique has been used on six patients The arteriograms of five of them (fig 2) show the extent of the disease Case 6, with a dissecting aneurysm of the common iliac artery, did not undergo arteriography since clinical examination sufficed.

Table II expresses briefly the clinical condition of the patients before and after the operation and gives some of the operation and perfusion details There were no failures

Conclusion

While this study covers only a few cases, the results are encouraging The perfusion technique interferes in no way with the operation and does not seem to have any disadvantages The risk of hæmorrhage is not increased, no difficulty has been experienced in securing a sound anastomosis, and hæmorrhage from the wound during the operation has not been troublesome At the end of the operation the clotting-time is restored to normal with protamine, no further anticoagulants are used, and in no case has postoperative hæmorrhage occurred

In table I one other patient is shown to have had a graft inserted He had a duodenal ulcer and was not perfused because of the supposed risk of hæmorrhage from his ulcer under the influence of heparin (Rains et al 1957) His graft thrombosed and ultimately he lost his limb

In the future a similar perfusion method can be adapted to maintain the vitality of both limbs in cases of aortic aneurysm Further, this method has an application in the treatment of the acutely ischæmic limb before restoring the circulation by washing out the products of tissue ischæmia Thompson and Campbell (1959) have shown experimentally how this may be possible The perfusate of dextran taken from the femoral vein is discarded and any tendency towards the " crush syndrome " (acute renal failure) averted (*Lancet* 1959)

It is also possible that an isolated neoplasm of a limb or organ could be effectively treated by perfusion of alkylating agents (Creech et al 1958)

We would like to thank the members of the heart-lung team—Prof A L d'Abreu, Mr L D Abrams, Mr J Fejfar, and Mr R Lightwood—for their help

THYROID ACROPACHY

T M D Gimlette
B A , M D Cantab , M R C P

SENIOR MEDICAL REGISTRAR, ST THOMAS'S HOSPITAL, LONDON, S E 1

Thyroid acropachy is one of the more odd manifestations of endocrine disorder, and how or why it arises is not at all clear The changes consist in clubbing of the fingers and toes, periosteal new bone formation involving the phalanges and other distal long bones, and swelling of the soft tissues of the extremities, especially those overlying the affected bones (figs 1 and 2) These changes are nearly always associated with past or present hyperthyroidism, exophthalmos, and pretibial myxœdema The disorder seems to be rare, judging by the few reported cases, but this apparent evidence of rarity is probably misleading because the condition is often rather inconspicuous and usually causes no symptoms or disability

I describe here six cases and compare the findings with those in thirteen others previously reported (see table)

Case-reports

Case 1—Man, aged 61 Hyperthyroidism with exophthalmos began in 1949, thyroidectomy was done the following year He was well for a year, but in 1951 pretibial myxœdema began to develop, and this grew steadily worse as did his exophthalmos He also became hypothyroid and has required thyroid gr 2 daily since 1952 Various treatments were tried for the pretibial myxœdema without effect, this and the exophthalmos have not changed since 1952 Early in 1955 he noticed painless swelling in both hands, the swelling increased for a few months and has remained unchanged since

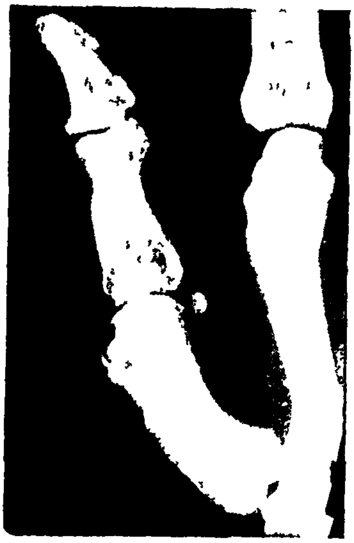

Fig 1—Case 1 X-ray showing characteristic new-bone formation in acropachy, most pronounced on extensor surface of first metacarpal

The changes of acropachy was more pronounced than in the other five cases The fingers and toes were clubbed Periosteal bone changes (fig 1) were present in the metacarpals, metatarsals, phalanges, and distal ends of the radius, ulna, tibia, and fibula There was considerable swelling of the soft tissues overlying the affected bones (fig 2) The joints were unaffected, and there was no muscular wasting, the affected parts were painless and not hot Apart from exophthalmos there was no change in the tissues of the face The serum calcium was 7 9 mg per 100 ml , phosphorus 5 0 mg per 100 ml , alkaline phosphatase 5 5 King-Armstrong (K A) units Erythrocyte-sedimentation rate (E S R) 16 mm in the first hour (Westergren) Skull X-ray normal

Case 2—Woman, aged 49 Hyperthyroidism and exophthalmos began in 1955 and thyroidectomy was done in April, 1956 Three months later hypothyroidism became evident and thyroid was started, gr 1 (later gr 3) daily, this has been continued up to the present time Pretibial myxœdema began to appear within a month of operation and steadily increased, exophthalmos also progressed In January, 1958, prednisone was given on account of increasing exophthalmos, this produced a temporary decrease in both exophthalmos and pretibial myxœdema, but after about three weeks, while high dosage was continued, both relapsed and became worse than ever Orbital decompressions were performed by Mr Harvey Jackson in March and April, 1958, with very good results Changes of thyroid acropachy were first noticed in June, 1958, and have become more pronounced since

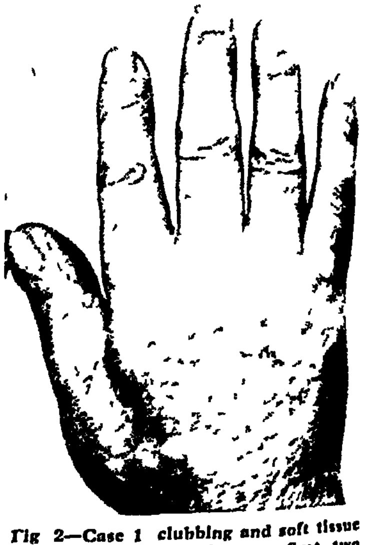

Fig 2—Case 1 clubbing and soft tissue swelling, particularly over first two metacarpals

The fingers and toes were clubbed There was pronounced soft-tissue swelling of the hands, less localised to the parts overlying affected bones than in case 1 Periosteal new-bone formation was present in the metacarpals and phalanges, but the X-ray changes were slight compared with those in case 1

FINDINGS IN 19 CASES OF ACROPACHY

Some stiffness and discomfort in the hands developed after the acropachy appeared, there was no evidence of arthritis or muscular wasting, but there was some loss of power in grip In the face there was no change other than residual effects of "mooning" from prednisone The serum calcium was 10 6 mg per 100 ml, phosphorus 3 6 mg per 100 ml, alkaline-phosphatase 9 K.A. units E.S.R. 10 mm in the first hour ^{131}I uptake by the thyroid was very low and was unaffected by thyroid-stimulating hormone given in two doses each of 10 units after three weeks without thyroid treatment Forearm blood-flow estimated by venous occlusion plethysmography was found to be normal The urinary œstrogen excretion was within normal limits Skull X-ray was normal Precipitin and agglutination tests on the patient's serum with thyroid antigen were negative

Case 3—Woman, aged 51 Thyroidectomy was done in 1946 on account of hyperthyroidism with exophthalmos Soon after operation pretibial myxœdema began to appear and increased steadily despite many attempts at treatment, finally it became very severe and extensive Since 1954 it has changed little Exophthalmos also increased for several years after thyroidectomy and some ophthalmoplegia developed, later both regressed a little The patient has been euthyroid since thyroidectomy

The hands were inspected from time to time for changes of acropachy There was nothing abnormal until July, 1958, when clubbing of the fingers was noted There was also some soft-tissue swelling of the hands, but no periosteal new-bone formation was detected in X-rays of the hands The serum calcium was 9 1 mg per 100 ml, phosphorus 4 9 mg per 100 ml, E.S.R. 20 mm. in the first hour

Case 4—Woman, aged 58 Thyrotoxicosis without eye signs developed in 1950 Thyroidectomy was done in 1951, and soon afterwards exophthalmos and pretibial myxœdema developed. The exophthalmos never became severe, the pretibial myxœdema advanced slowly with fluctuations but has never become extensive In 1957 thyrotoxicosis recurred and was treated with radio-iodine, there was no change in exophthalmos and slight increase in pretibial myxœdema. Changes of thyroid acropachy were first noticed in 1958

There was no clubbing of the fingers, but there was periosteal new-bone formation and overlying soft-tissue swelling which involved the first metacarpal obviously and was possibly present elsewhere in the hands The condition was symptomless The localisation of the changes of acropachy in this patient are notable, the absence of clubbing is unusual but has been described before (Diamond 1959) Otherwise the changes were quite typical Serum calcium 10 4 mg per 100 ml, phosphorus 3 9 mg per 100 ml, alkaline-phosphatase 6 K.A. units, E.S.R. 7 mm. in the first hour

Case 5—Woman, aged 62 Hyperthyroidism developed in 1944 and was treated by thyroidectomy, subsequently the patient became hypothyroid and has taken gr 2 of thyroid daily since. Moderate exophthalmos developed soon after operation and has been unchanged since Pretibial myxœdema began to appear on the left leg eight months after operation, became bilateral, and has gradually progressed and become severe The patient noticed swelling over the second left metacarpal after minor trauma in 1957 When acropachy was first present is uncertain, it causes no symptoms The fingers are clubbed, and periosteal new-bone formation and soft-tissue swelling, notably patchy in distribution, involve the metacarpals and phalanges Precipitin and agglutination tests on the patient's serum with thyroid antigen were negative

Case 6—Woman, aged 36 Hyperthyroidism developed in 1955 and was treated by thyroidectomy Moderate exophthalmos was present before thyroidectomy and has not greatly changed since Pretibial myxœdema appeared a few months after thyroidectomy and became moderately severe Hyperthyroidism recurred in 1959 and was treated with radioactive iodine It was noted then that the fingers were clubbed and the soft tissues of the hands thickened There was very slight periosteal new-bone formation.

Discussion

Acropachy is the last and rarest part of a syndrome, the other parts being hyperthyroidism, exophthalmos, and pretibial myxœdema, usually arising in that order The changes have been thought to be due to a disorder of hormone secretion by the anterior pituitary, and in two patients with acropachy eosinophil hyperplasia or adenoma has been described (Freeman 1958) In the present series skull X-rays showed normal pituitary fossæ Possibly autoimmunisation plays a part, but so far there has been no positive evidence The great majority of described cases of acropachy have been in males

Why the syndrome of Graves' disease with pretibial myxœdema and acropachy should develop piecemeal over a variable and often long period is obscure In the cases described here and in other reports, the changes of acropachy have invariably been found in association with other features of the syndrome, usually all of them, and acropachy has not been described as occurring alone or in any other condition Acropachy usually appears some time after the other components of the syndrome, when hyperthyroidism has been treated, and it is therefore rarely present with active hyperthyroidism as in case 6 and in a case reported by Freeman (1958) The interval between the onset of hyperthyroidism and the recognition of acropachy varied from a few weeks to twenty-eight years (see table) Hyperthyroidism has been recognised at some stage in all patients with acropachy except one (Greene 1951), exophthalmos has been present in all, and pretibial myxœdema in the majority

The changes in thyroid acropachy seem to be unique, and the question of differential diagnosis hardly arises In some of the earlier described cases there was confusion with hypertrophic pulmonary osteoarthropathy In acropachy the periosteal bone changes are quite different in appearance they simulate bubbles on the bone surface, and they are differently situated, being on more peripheral parts of the skeleton Also the characteristic heat, pain, and evidence of increased bone blood-flow (Ginsberg 1958) in pulmonary osteoarthropathy is absent in acropachy The soft-tissue thickening of acropachy is an important diagnostic feature, particularly when localised over the affected bones In acromegaly, occasionally associated with hyperthyroidism, the changes in the hands and elsewhere should not be confused with those of acropachy, although some new bone formation occurs There is a rare familial condition—idiopathic osteodystrophy or pachydermoperiostosis (Angel 1957) in which clubbing and thickening of the tissues of the hands, feet, and face develop early in adult life This condition has some resemblance to acropachy, but it is not associated with other features of the acropachy syndrome

Symptoms from thyroid acropachy are unusual, and treatment is therefore not an important problem There may be complaint of stiffness due to generalised soft-tissue swelling of the hands, but the joints do not seem to be involved, and there is no evidence of muscular weakness or wasting The natural course of thyroid acropachy is uncertain, in some patients there has been no change for several years, possibly, as with other features of Graves' disease, partial or complete remission may occur naturally after a time

The frequency of thyroid acropachy is very difficult to determine since it may appear so many years after the onset of thyrotoxicosis that an ordinary follow-up would be inadequate The present series of six cases were met with over a period of four years during which there were about five hundred new cases of hyperthyroidism Possibly acropachy eventually develops in about 1% of patients with hyperthyroidism

Thyroid acropachy must be added to the long list of miscellaneous conditions associated with clubbing, and the changes in acropachy are not readily explained by any of the mechanisms or causes of clubbing which have been suggested in certain other disorders

Summary

Six cases of thyroid acropachy are described Acropachy consists of clubbing of fingers and toes, distal periosteal bone change, and swelling of the overlying soft tissues

The condition arises occasionally as a final phase of development of the acropachy syndrome of hyperthyroidism, exophthalmos, and pretibial myxœdema

The cause of acropachy is obscure, but apparently in some circumstances certain of the peripheral tissues undergo peculiar changes, possibly under the influence of a pituitary hormone

I am grateful to Dr H K Goadby, Prof E P Sharpey-Schafer, Dr J S Richardson, Dr H J Anderson, and Dr H J Wallace for permission to describe cases under their care

PREGNANCY AFTER TUBERCULOSIS OF THE FALLOPIAN TUBES

J A L Johnston
M D Belf
SENIOR PHYSICIAN (FORMERLY PATHOLOGIST)

S W Liggett
M B Belf, F R C S E, M R C O G
GYNÆCOLOGIST

ALTNAGELVIN HOSPITAL, LONDONDERRY, NORTHERN IRELAND

Rabau first reported a pregnancy after the successful treatment of proved endometrial tuberculosis in 1952, and several other cases have been described since We have been unable to find any reference to proved tubal tuberculosis followed by pregnancy, although in one of Earn's (1958) cases of endometrial tuberculosis the left fallopian tube was palpable at the first examination We therefore present the following case-report, which shows that pregnancy is possible after tuberculosis of the fallopian tubes has been treated medically

Case-report

The patient, aged 25, who had been married 9 months, was referred, on June 29, 1955, to S W L with suspected extra-uterine pregnancy Her last normal menstrual period was at the end of April—i e, 8–9 weeks previously From the last week in May until the time of examination she had had irregular vaginal bleeding, and had passed occasional small clots She also had cramp-like lower abdominal pain She denied any previous serious illness or familial tuberculosis, although 2 weeks later her mother underwent nephrectomy for renal tuberculosis

Examination

She seemed to be healthy and was of medium build Her heart and lungs were normal, and the temperature and pulse-rate were not increased The abdomen moved easily on respiration, no tumour was felt but there was slight tenderness on both sides of the lower abdomen Bimanual examination revealed a slightly enlarged uterus and an irregular, slightly tender mass, which appeared to be fixed to the uterus, in the pouch of Douglas

The patient was admitted to a nursing home for observation because the diagnosis was in doubt On June 30 her condition was unchanged, but next evening she had fairly severe abdominal pain She was not in a state of shock and she had no signs of intra-abdominal bleeding Because the mass in the pouch of Douglas was more tender, an examination under anæsthesia and possibly laparotomy was planned for next morning

Operation and Course

Under general anæsthesia (July 2) the previous findings in the pelvis were confirmed As an ectopic pregnancy could not be excluded, laparotomy was performed through a midline sub-umbilical incision The omentum was adhering to the uterine fundus and covering the pelvis When this was freed the uterus was found to be enlarged to the size of a 6–8 weeks pregnancy by multiple small fibroids The mass in the pouch of Douglas comprised the swollen and inflamed fallopian tubes The left tube was distended to at least 1 in diameter, and the right to about $^1/_2$ in., thin yellow pus was escaping from their fimbrial

ends, from which a swab was taken for examination The abdomen was closed without drainage, and the patient returned to the ward in good condition

Direct microscopical examination (J A L J) showed pus-cell debris and necrotic material with some intact leucocytes and lymphocytes, and a few giant cells No gram-positive organisms or acid-fast bacilli were seen, but a tuberculous infection was suspected Culture of the pus for these organisms was arranged

By the 3rd postoperative day the patient had a temperature of 102 F, with a corresponding tachycardia That evening she had a hæmoptysis, and was examined by J A L J The heart sounds and rhythm were normal, and the blood-pressure was 120/80 mm Hg The patient said she had had a pain in the left axilla at the level of the 6th or 7th rib, some 36–48 hours before the hæmoptysis A slight friction rub and a few crepitations were heard in the left submammary area The respiratory rate was increased, but deep breathing did not cause pain Sputum (3 specimens) was negative for tubercule bacilli

A small pulmonary embolus was diagnosed provisionally, but in view of the abdominal findings the possibility of pulmonary tuberculosis was considered, and treatment with streptomycin and isoniazid was instituted The pyrexia and tachycardia disappeared in 3 weeks, and chest radiographs on July 18 showed a very small effusion within the left pleural cavity, but the rest of the lung fields were clear A further radiograph on Aug 3 showed that the left costophrenic sinus was clear, although increased density in this area persisted Convalescence was uneventful, and the patient was allowed home in mid-August, her medical treatment being continued

When reviewed on Sept. 10, the patient's general condition had improved, although pyrexia (99 6–100 4°F) had returned, with some sweating Her weight had increased by $4^1/_2$ lb Radiographs showed no active lesion in the lungs, but a large calcified abdominal gland was noticed The hypogastrium was tender

The results of the bacterial cultures became available Blood-agar plates were sterile after 4 days' incubation, but after 7 weeks on Lowenstein and Jensen medium typical colonies of tubercle bacilli were present Acid-fast and alcohol-fast tubercle bacilli were seen microscopically Examination of the blood showed hæmoglobin (Hb) 90%, red blood-cells 4,000,000 per c mm , white blood-cells 11,000 per c mm , hæmatocrit 35%, erythrocyte-sedimentation rate (E S R) 10 mm in the 1st hour (Westergren) Streptomycin therapy was replaced by *p*-aminosalicylic acid, and isoniazid was continued

On Oct 12 the patient's temperature was lower and her weight had increased. By Nov 1 her temperature was normal apart from an occasional spike, and the E S.R had fallen to 7 mm in the 1st hour Her condition remained unchanged for several weeks, but by Dec 28 a definite pattern of pyrexia was apparent during the progestational phase of the menstrual cycle Her weight had increased further but the E S R had risen slightly to 11 mm in the 1st hour, and the hæmatocrit had fallen to 36%

Menstruation had returned in September, without pain or intermenstrual bleeding On Jan. 30, 1956, no abnormality was detected in the abdomen, and on vaginal examination the uterus seemed normal The right fallopian tube could not be felt, but the left was still much enlarged and thickened

On Feb 3 the E S R was 18 mm in the 1st hour, Hb 84%, and hæmatocrit 36% No lung lesion was found clinically or radiographically The patient was readmitted to the nursing home for complete rest, and further streptomycin was given By March 9 her condition had improved considerably, and she was allowed to go home She still had pyrexia in the progestational phase of the menstrual cycle, but it now never rose above 99°F The E S R was 11 mm in the 1st hour, Hb 88%, and hæmatocrit 36%, her weight had increased to 11 st 10 lb

First Pregnancy

The improvement continued, but on May 23 she complained of some dizziness, and although no 8th nerve lesion was detected streptomycin was discontinued as a precautionary measure On June 6 menstruation was 14 days overdue, and pregnancy was confirmed by a positive Hogben test in mid-July By the end of July, because she was much troubled by vomiting, the *p*-aminosalicylic acid was replaced by streptomycin On Aug 3 she aborted incompletely a ten-week fœtus Next day, at curettage under general anæsthesia, several fibroids were palpated Convalescence was complicated by a thrombophlebitis of the right internal saphenous vein Menstruation returned on Sept 9 On Sept 29 the E S R was 10 mm in the 1st hour

At postoperative review on Oct 4 the right leg showed no sign of the previous thrombosis The cervix was healthy, and the uterus and fibroids were well involuted She had slight dysuria, but no cause was found

At the end of October dizziness and tinnitus had returned, but the E S R was 8 mm in the 1st hour, and her general condition was good Streptomycin was stopped, and all other treatment was scaled down She was not seen again until March 8, 1957, when she had had no treatment for about 2 months She was well, her weight had increased, and the E.S R. was 3 mm in the 1st hour

Second Pregnancy

At the end of May she again reported that menstruation was overdue (last menstrual period April 16) and a Hogben test confirmed pregnancy In view of the previous miscarriage 6 (25 mg) pellets of progesterone were implanted deep to the fascia lata She was again given *p*-aminosalicylic acid

Pregnancy proceeded normally (blood-pressure 120/80 mm Hg, no albuminuria) until Sept 9, when decalcification of her teeth was noted She was given calcium and vitamin D, and for the next 2 months she seemed to be normal

Just before Christmas her right leg had been swollen for 5 days but had improved since On Jan 3, 1958, slight œdema was found, but no evidence of any clot formation The blood-pressure was 130/80, a trace of albuminuria was found, and the fœtal heart was heard The fœtal head had not engaged in the pelvic brim The patient was advised to rest

On Jan 10 the blood-pressure had risen to 150/90 and the urine still contained a slight trace of albumin. The fœtus was presenting by the vertex, and the fœtal heart was heard The patient was advised to continue resting at home She was admitted to the nursing home on Jan 17 as she feared she might be isolated at her home in the country by a snow storm With complete rest in bed the blood-pressure fell to 140/90 and the urine became albumin-free

Labour started spontaneously on Jan 28—i e , 285 days after the first day of her last menstrual period Progress was very slow, with weak irregular pains, after 36 hours the cervix was only three-fingers dilated, and the head was still free In view of the length of labour, the uterine inertia, and the non-engagement of the head, a lower-uterine-segment cæsarean section was performed on Jan 29, and a live female infant weighing 10 lb was delivered At operation cephalopelvic disproportion was noted, and the fibroids were still present, but both fallopian tubes looked normal, without evidence of previous disease There was a large placental infarct, and the liquor was heavily stained with meconium

Convalescence was uneventful at first Careful and regular examinations showed no evidence of venous thrombosis The patient got up daily from the 3rd day, and moved about her room On the 10th postoperative day, while she was cleaning her teeth in the bathroom, she collapsed from a pulmonary embolus, and despite morphine and intravenous heparin she died 20 minutes later The infant has progressed satisfactorily

Discussion

Despite this patient's unfortunate death her history shows that in cases of tuberculous salpingitis the radical and surgical treatment previously practised by Stallworthy (1952) and others may no longer always be necessary, and that with present-day medical treatment even considerable damage to the fallopian tubes by tuberculous disease does not always mean sterility

This case was treated along the lines recommended by Hallum and Thomas (1955) and Norburn and Walker (1956) with the addition of isoniazid 100–150 mg daily As in Rabau's case, the first pregnancy after treatment ended in early abortion We do not think the post-operative thrombophlebitis was necessarily associated with the tuberculous infection

Summary

A patient with tuberculosis of the fallopian tubes, treated medically, had afterwards two pregnancies which resulted in an abortion and a healthy infant

At the time of the cæsarean section both fallopian tubes were free from macroscopic signs of inflammation

Three consecutive operations were followed by venous thrombophlebitis The third proved fatal because of pulmonary embolism

We wish to thank Dr D S Wilson and Lieut -Colonel D G C Whyte, D S O, for their assistance with the anæsthesia and radiology, and Miss E Scott, S R N, S C M, and her staff for nursing the patient

STERNAL TRACTION FOR THE FLAIL CHEST

G C Robin
M B Glasg, F R C S, F R F P S
REGISTRAR, ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, LONDON, W 1

SINCE Jones and Richardson (1926) first described a method of controlling paradoxical respiration after chest trauma by skeletal traction on the sternum, using a gynæcological "bullet forceps", several reports have suggested other methods and instruments found valuable

Butler (1938) and Williams (1948) advocated the use of towel-clips to grasp the ribs, Jaslow (1946) used coat-hanger hooks screwed into the sternum All three workers employed weight traction

Proctor and London (1955) used "cup hooks" in the sternum fixed to a special bed frame, while Heroy and Egglestone (1951) made drill holes in the sternum and applied a clamp and 10 lb traction Ritter and Kaye (1944) used perichondral wires with weight traction Other workers have advocated open reduction of sternal fractures and fixation with plates (Hendry 1957) or crossed Kirschner wires (McKim 1943), and finally Coleman and Coleman (1950) suggested open reduction of the multiple rib fractures and fixation with wire sutures Birchfield and Grant (1956) also recommended this method of managing the "stove-in" chest

Recently for sternal fixation in a patient with multiple injuries I used an instrument available in most traumatic centres—i e, a skull calliper—and found it to be both easy to apply and effective

Case-report

A man, aged 27, was involved in an accident at work in a textile factory on Jan. 6, 1959, when his right hand was trapped in a machine His arms, head, and trunk were drawn between the rollers, crushing him and at the same time enveloping him in several layers of fabric The machine had to be reversed to roll him out and he was removed from the wrappings unconscious, deeply cyanosed, and not breathing After artificial respiration by a workmate he regained consciousness On arrival in hospital, about half an hour after the accident, he was conscious but grossly shocked His pulse and blood-pressure were unrecordable, and although there was no cyanosis there was severe respiratory distress His injuries included compound fractures of the left humerus and left radius and ulna, a fracture of the ascending ramus of the mandible on the right, a fracture of the neck of the right scapula, fractures of the right radius and ulna, a subtrochanteric fracture of the right femur, and finally bilateral fractures of the second to ninth ribs inclusive in the anterior axillary lines (fig 1) The entire anterior chest wall, an area measuring about 135 sq in, was involved in paradoxical movement, and he showed the orbital hæmorrhages of traumatic asphyxia

After immediate splinting of the limb fractures, strapping the chest, and rapid infusion first of dextran and then of blood, his condition improved enough to allow operation, which was performed under general anæsthesia First the chest wall was

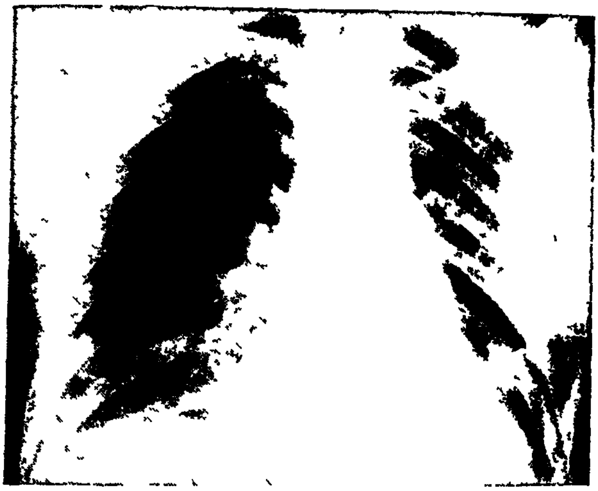

Fig 1—Chest radiograph on the day after injury, showing multiple bilateral rib fractures

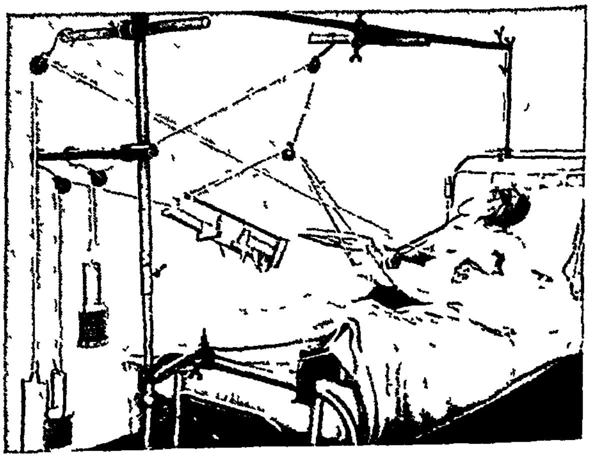

Fig 2—Patient in bed with skeletal traction in situ

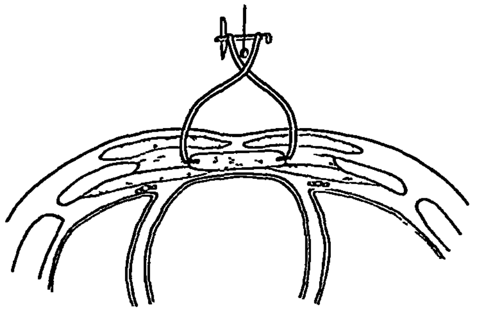

Fig 3—Diagrammatic cross-section of anterior chest wall at the level of the 5th intercostal space

enclosed in circumferential strapping, and then routine toilet and manipulation of the fractures was performed The limb fractures were immobilised in plaster After a total transfusion of 9 pints of blood his general condition was good, although, despite the strapping, there was still considerable paradoxical movement of the anterior chest wall

For three days the improvement was maintained, and then a "wet-lung syndrome" supervened and the patient rapidly deteriorated The respiratory rate rose to 60 per min and the pulse-rate to 160 per min The hæmoglobin fell from 92% on the morning after injury to 80%, and the white-blood-cell count rose to 25,600 per c.mm Fixation of the flail chest segment was regarded as essential, and this was carried out as follows

Under local anæsthesia, a transverse incision about 5 in long was made across the sternum at the level of the sixth costal cartilage The upper part of the rectus abdominis was divided, and the fifth intercostal space on each side was exposed by incising the anterior intercostal membrane A Crutchfield skull calliper was used to grasp the sternum, the prongs biting into the lateral edges of the bone between the fifth and sixth cartilages on each side The calliper was then tightened to gain a firm hold and traction of 14 lb was applied over pulleys (figs 2 and 3)

The patient's condition improved immediately and dramatically The respiratory rate fell to 30 per min. and the pulse-rate to 110 The cyanosis cleared, the pain in the chest was relieved, and the patient was able to cough But the paradoxical movement, though much reduced, was still present, and in fact could not be completely overcome even by pulling manually on the calliper with a much greater force With this increased pull there was some discomfort from the calliper, but with 14 lb there were no adverse symptoms The wound was finally closed round the calliper

Within twenty-four hours, the chest was clinically and radiographically dry, and thereafter the improvement was maintained. On Jan. 17, again under general anæsthesia, with the traction still in place, open reduction of the two forearm fractures was performed. Even at this time temporary removal of the traction was followed by rapid return of respiratory distress, but by mid-February there was radiographic early union of the rib fractures, and the traction was discontinued without return of paradoxical respiration Since then progress has been uneventful Apart from slight delay in the left forearm, the limb fractures have united satisfactorily, the patient's general condition is excellent, and there is no significant deformity of the chest wall.

Discussion

With the increasing number of road accidents, "stove-in" chests are being seen more commonly, and are usually the result of crushing by the steering-wheel during collision The injury is frequently anterior and often involves the sternum as well as the ribs Furthermore, frequently there are other injuries, sometimes very severe

Although Hulman (1957) suggests that, in the management of such injuries, tracheotomy and bronchial aspiration are all that is required and gives physiological reasons for this, and Shefts (1956) states that "tracheotomy is almost mandatory", there are disadvantages in this method—particularly the loss of the protective function of the upper air passages against infection Many surgeons, therefore, prefer to avoid tracheotomy if possible Open reduction of rib fractures, recommended in many centres, has the great disadvantage of converting a closed chest injury into an open one Coleman and Coleman (1950) and Birchfield and Grant (1956) both confirm that the parietal pleura is always torn below the rib fractures, and recommend routine intercostal drainage after operation Nevertheless the operation is a major one in a patient who may be in a grave state, as much from other injuries as from the thoracic lesion Furthermore the operation requires expert thoracic surgical skill and nursing, neither of which may be available in the traumatic centre to which the patient is first admitted

Other methods of skeletal traction have disadvantages Towel clips placed round ribs or pericostal or perichondral wires may, as Shefts (1956) says, injure the internal mammary artery in their application, and "not infrequently the pleura or the lung may be involved" Even if available, single screws in the sternum, cup hooks, and coat-hanger hooks are not mechanically sound Clamps fixed to the sternum through drill holes involve the risk of the drill perforating the posterior sternal plate and injuring the mediastinum

Moreover, with involvement of a large area of chest wall in the paradoxical movement, the forces required to stabilise the flail segment are relatively great Although Cooper (1957) found $2^1/_2$ lb traction effective, in this case not even 14 lb was enough to control the flail segment completely In normal quiet respiration the difference in negative pressure in the pleural cavity between inspiration and expiration is said to be 5 mm Hg, or about $^1/_{10}$ lb per sq in (Wright 1952) In flail chests, it is probably this decreasing negative pressure that causes the indrawing of the unstabilised segment of the thoracic cage on inspiration In this patient, therefore, a theoretical traction force of $13^1/_2$ lb should have controlled the anterior chest wall Nevertheless even a much greater force did not completely prevent some indrawing Presumably, therefore, the gross respiratory distress of a patient with a "stove-in" chest must result in an intrapleural pressure swing of much more than 5 mm Hg, and thus the traction force required is consequently increased

Thus very firm skeletal traction is required for adequate management of these cases The skull calliper allows such firm traction to be applied, and furthermore is simple to apply, with little risk The dissection required is not deep enough to involve the left pleural reflection, and the application of the clamp directly to the lateral edge of the sternum avoids the internal mammary artery which runs usually half an inch laterally Its use is therefore advocated in the management of flail chests when the sternal segment of the chest wall is part of the unstable section

Summary

In a man with severe multiple injuries a skull calliper was applied successfully to control paradoxical respiration in the flail chest These allowed firm traction to be applied, and, although indrawing of the affected segment was not entirely prevented, the improvement in the patient's condition was dramatic and immediate

I thank Dr J H Dixon, but for whose skilful anæsthetics this treatment could not have been carried out, Mr D M Dunn, who allowed me to treat this case in the early stages, for his help and encouragement in preparation of this paper, and Miss M Fishwick for fig 3, and the photographic department of the Royal National Orthopædic Hospital for fig 1

THROMBOTIC THROMBOCYTOPENIC PURPURA

REMISSION ON TREATMENT WITH HEPARIN

L. Bernstock
M R C S , D Path
PATHOLOGIST

Cedric Hirson
M R C P
SENIOR MEDICAL REGISTRAR

ST HELIER HOSPITAL, CARSHALTON, SURREY

Since the original description of thrombotic thrombocytopenic purpura by Moschowitz (1924, 1925), about a hundred cases have been reported Although in the clinical presentation considerable variation has been noted, there is a diagnostic syndrome of acute febrile hæmolytic anæmia, thrombocytopenia, and transient neurological signs present at some stage of the disease The course is generally relentless and fatal We report here a case in which heparin apparently induced two remissions

Case-report

Mrs A., aged 27, was admitted on Nov 28, 1958, for an acute hæmorrhagic illness, with fever, severe anæmia, slight icterus and sore throat, and a raised erythrocyte-sedimentation rate 9 days previously she had had an acute upper respiratory infection, followed 2 days later by a sore throat, generalised purpura of skin and mucous membranes, and vaginal bleeding Sulphonamide and penicillin therapy had been given by her family doctor 5 weeks before this a urinary-tract infection had been treated with sulphonamides

Flexion in one knee was limited probably because of rheumatoid arthritis 4 years previously (This had been associated with hyperglobulinæmia [total protein 8 g per 100 ml globulin 4 g] and had been treated successfully with corticotrophin) The liver, spleen, and superficial lymph-nodes were not palpable, the retinæ, nervous system, and mental state were normal, and there was no abnormality of the cardiorespiratory systems Blood examination showed a hæmolytic anæmia with thrombocytopenia

Hæmoglobin 37% (5 4 g per 100 ml) Packed-cell volume 17% Mean corpuscular hæmoglobin concentration 32% Anisocytosis and poikilocytosis, many spherocytes and fragmented red cells Normoblasts 21 per 100 white cells, reticulocytes 21%, platelets 60,000 per c mm , white cells 16,900 per c mm (polymorphonuclears 69%, eosinophils 2%, lymphocytes 25%, metamyelocytes 4%) Many of the lymphocytes were early forms Coombs' antiglobulin and platelet antibody tests negative Several preparations for L E (lupus erythematosus) cells were negative and the serum proteins were normal (Total protein 7 g per 100 ml , albumin 4 5 g per 100 ml , globulin 2 5 g per 100 ml)

Marrow from the iliac crest showed hyperplasia of the normoblast series and no abnormality of the white-cell series Megakaryocytes were present in normal numbers but showed none of the cytoplasmic granularity usually associated with platelet production Wassermann reaction was negative A diagnosis of acquired hæmolytic anæmia with thrombocytopenia was made

Progress

On the 2nd day in hospital the patient developed paræsthesiæ and weakness of the right arm and face with slurred speech, and the diagnosis was altered to thrombotic thrombocytopenic purpura The hæmoglobin was now 22% (3 3 g per 100 ml) and the platelets 30,000 per c mm Prednisone, 40 mg daily, was given for 2 days, and then increased to 60 mg with the addition of 40 units of corticotrophin daily 12 pints of blood, partly fresh, taken and administered through siliconed apparatus, was given to raise the low hæmoglobin and platelet levels The hæmoglobin level repeatedly reached 60% but always fell to pretransfusion figures in about 2 days

The general condition remained grave Purpura and vaginal bleeding continued, and once or more daily there were neurological episodes, lasting 2-12 hours, with stupor, paresis, and behaviour and mental changes

A feature of the blood-film at this stage was the daily variation in the number of spherocytes and fragmented red cells and the big variation in the number of primitive white cells

On the 20th day heparin therapy was started, with a small dose of 1000 units intramuscularly every 4 hours This did not increase coagulation-time, which was 7 minutes (Lee and White) After a day's heparin treatment there were no more neurological episodes, and by the 2nd day there was no fresh hæmorrhage, therefore the same dosage was continued The hæmoglobin level and platelet-count rose steadily (see fig) without further blood-transfusions The white-cell count returned to normal levels although some primitive cells persisted, the reticulocytes fell and abnormal red cells disappeared

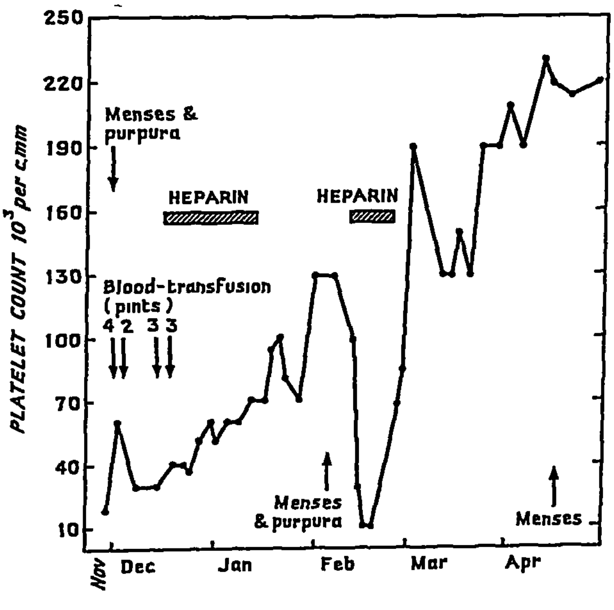
Corticoid therapy was slowly discontinued and heparin therapy was stopped after 4 weeks The patient was discharged ambulant and symptom-free with hæmoglobin 75% (10 9 g per 100 ml), and white cells 6200 per c mm (polymorph neutrophils 70%, eosinophils 4%, lymphocytes 25%, monocytes 1%) No abnormal red cells Platelets 105,000 per c mm Reticulocytes 4%

Second Episode

For 4 weeks she remained well In the 5th week her usual menstrual loss started, but it was heavier than usual and accompanied by a sore throat and purpura of skin and mucous membranes The hæmoglobin was 66% (9 1 g per 100 ml)—a drop of 9% in 3 days—and the platelet-count 130,000 She was readmitted and heparin therapy, without corticoids or blood-transfusion, was begun in the same dosage as before Next day the platelets had fallen to 30,000, but there was neither new purpura nor excessive vaginal bleeding Menstruation ceased 2 days later Treatment was discontinued on the 12th day, and she was again discharged free of symptoms or signs Since then, menstruation and dental extractions have been unaccompanied by excess blood loss or hæmatological changes

Present Condition

The patient remains free from symptoms or abnormal signs The most recent blood-count, 40 weeks after the completion of the second course of treatment, is hæmoglobin 84% (12 1 g per 100 ml), white cells 6700 per c mm (differential count normal), platelets 160,000 per c mm



Discussion

In the first episode therapy was multiple but remission followed administration of heparin In treating the relapse only heparin was used The patient's recovery on this treatment is noteworthy because spontaneous remission in thrombotic thrombocytopenic purpura has not been reported, and death is usual within a month of the onset

Delbeke and Coussement (1956) described the case of a child of 7 years who survived for 5 months Thrombocytopenia but not anæmia remitted on steroid therapy A relapse, uninfluenced by intensive therapy, followed 2 months after discontinuing treatment The case of Engel et al (1947) in which splenectomy was performed, remitted for 3 months but died in acute relapse

We have found no examples of classical thrombotic thrombocytopenic purpura running a chronic course Protracted cases appear to fall into three groups

Rapid termination has been reported after long and varied illness which at first lacked the characteristics of the disease (Laszlo et al 1947, Fitzgerald et al 1947, Biegelman 1951, Comess and Oyamada 1952)

The cases described by Brown and Norman (1946), Gendel et al (1952), Fisher and Creed (1955), and Baez-Villasenor and Ambrosius (1957) appear to have been unclassifiable hæmatological disorders terminating in thrombotic thrombocytopenic purpura

Gardner et al (1951) and Meacham et al (1951) recorded cases of acquired hæmolytic anæmias, responding to splenectomy, which in terminal illness showed the features of the syndrome

We have been able to trace five non-fatal cases

Shapiro et al (1957) reported a 32-month survival after splenectomy and corticoid treatment evidence of hæmolysis persisted Siegel et al (1954) reported a complete remission of similar duration, also following splenectomy and steroid therapy L E cells were demonstrated 7 months after operation Rodriguez et al (1957) have reported complete remission for a year following splenectomy, and Burke and Hartmann (1959) complete remission in two cases following very large dosage of corticoids

Treatment with blood-transfusion and corticoids is customary, and splenectomy has been performed on a number of occasions Only in the cases cited above has therapy been of possible value

In 1947, at a time when no case had been diagnosed during life, Singer et al suggested the use of heparin The suggestion was repeated, without clinical trial, by Singer et al (1950) and Hauser et al (1951) We have been able to find only two cases in which heparin was used Adelson and Stefanini (1952) gave heparin sodium 75 mg intravenously 4-hourly but abandoned the treatment after 2 days, and Adelson et al (1954) apparently used the same dosage unsuccessfully for the same time in the terminal stage of a short illness Hence the case we present is the first in which heparin seems to have induced a remission

The mode of action of heparin, as an anticoagulant, is controversial It prevents the agglutination and disintegration of platelets and may remove thrombin, thus interfering with the formation of fibrin O'Brien (1958) suggested that it acts by combining with Christmas factor, thus lengthening the coagulation-time

Despite the hazards inherent in giving heparin in the presence of hæmorrhage, its use in thrombotic thrombocytopenic purpura has a basis in the pathology of the condition

Gore (1950) suggested that the primary defect is a subendothelial collection of hyaline material in the capillaries, this substance projects into the lumen and is covered by healthy endothelium With excessive hyaline deposition, rupture takes place, platelets are withdrawn from the circulation by deposition on the roughened surface, and clotting follows Using fluorescein-conjugated antibody, Craig and Gitlin (1957) identified the hyaline thrombi as a derivative of fibrinogen or fibrin The view that the condition is primarily associated with damage to capillaries and arterioles is stressed by Meacham et al (1951), Orbison (1952), and March (1954)

Further evidence of the secondary nature of the thrombocytopenia appears to be demonstrated in our case We observed a marked fall in platelet-count only after clinical relapse with purpuric lesions and a fall in hæmoglobin level

Symmers (1956) found the histological changes of thrombotic thrombocytopenic purpura before the symptoms had become manifest

Hinstell and Kligerman (1959) have pointed out the high incidence of a hæmorrhagic diathesis in hyperglobulinæmias of various types They suggest that some globulins may combine with clotting factors with resultant hæmorrhage When such combinations dissociate, large amounts of clotting factors are released with consequent clot formation These workers have demonstrated the combination of globulins with proaccelerin, accelerin, convertin, prothrombin and fibrinogen This mechanism might play a part in the ætiology of thrombotic thrombocytopenic purpura in cases where hyperglobulinæmia is present

Summary

In a case of thrombotic thrombocytopenic purpura clinical and hæmatological remission occurred on two occasions after the use of small doses of heparin

We wish to thank Dr J B Harman for his permission to publish this report and Mrs M Moore and the technicians of the hæmatological laboratory

" The relationship between Science and Art is similar in function to the very legs we stand and move on These must be both independent of each other, and, at the same time, harmonious and simultaneous in synchronisation "—Mr YEHUDI MENUHIN at a meeting of The Royal Institution of Great Britain on Jan 30, 1959

Preliminary Communications

HODGKIN'S DISEASE: A MATERNAL-TO-FŒTAL LYMPHOCYTE CHIMÆRA?

THE hypothesis we describe here is based on acquired tolerance, the probable ability of maternal leucocytes to reach the fœtal circulation, and the immunological theory of carcinogenesis.

Acquired tolerance is the "outcome of an induced central failure of the mechanism of immunological response brought about by the exposure of animals to antigenic stimuli before the maturation of the faculty of immunological response".[1] That this phenomenon exists has been amply demonstrated.[2]

If maternal leucocytes could enter the fœtal circulation by transplacental passage at a time when the fœtus is immunologically tolerant, then these leucocytes could persist and reproduce. The lymphocyte is most likely to do this because it has a long life-span [3,4] and can reproduce.[5-8] That maternal red blood-cells may reach the fœtus has been shown by several studies.[9,10] Since the small lymphocyte is of the same order of size as the red blood-cell it should also be able to pass the placental barrier. The mature fœtus (adult animal) could then be a lymphocyte chimæra. Maternal tumour cells, which are larger than red blood-cells, occasionally pass this barrier.[11]

In artificially produced lymphocyte chimæras, tolerance may be one-sided. In both radiation chimæras and chimæras produced by injecting newborn tolerant mice with homologous lymphocytes, homologous ("runt") disease develops.[12-14] This is manifested by weight loss, diarrhœa, dermatitis, and a peculiar atrophy and granuloma formation in the spleen and lymphoid organs of the chimærical mice. Death finally results. Occasionally lymphomas also develop (see below). This reaction occurs only in those animals given homologous lymphocytes or homologous bone-marrow containing lymphocytes. Homologous liver cells, or other homologous non-lymphatic tissues, do not cause the reaction. Radiation alone or radiation together with injection of isologous lymphocytes does not lead to this reaction. Several workers have suggested that homologous disease results from sensitisation of the homologous transplanted lymphocytes by host antigens, and these lymphocytes then react immunologically against the host.[12-15] Peripheral-blood lymphocytes can cause homologous disease.[16]

An immunological theory of carcinogenesis has been proposed.[17,18]

Briefly this is that carcinogenic chemicals, viruses, or ionising-radiation agents act by combining with or altering so-called "identity" proteins or "self-markers" in cells. As a result the identity proteins become altered antigenically. This antigenically altered material acts as an autoantigen, and a locally manufactured cellular antibody develops, directed against this now "foreign" material. At the same time the agents which caused the antigenic change cause excessive stimulation and growth in the cells which have had their identity proteins immunologically altered.

Thus there exists a selective immune force which will favour the growth of those cells with the fewest identity proteins. These cells will survive and proliferate. The loss of "identity proteins" constitutes the malignant change, for it is these identity proteins which, by an interchange between adjacent cells, normally regulate the normal organised relationship between cells.[19] It is the same or closely related "self-markers" which permit the recognition of "self" and "not-self" in homografts and autografts.[20] Various degrees of tolerance can exist in the mature animal, according to the age of the fœtus at the time of arrival of the maternal lymphocytes. In the imperfect partially tolerant lymphocyte chimæra the stage is set for an immunological warfare in which a set of lymphocytes with few or no identity proteins may be selected. These lymphocytes are then malignant.

We suggest that patients with Hodgkin's disease may be maternal-to-fœtal lymphocytes chimæras of a natural variety—that is, maternal lymphocytes reached them when they were tolerant fœtuses and that the above sequence of events takes place. Murine lymphomas have developed in both radiation lymphocyte chimæras [21] and parental-to-F_1 (offspring) non-irradiated lymphocyte chimæras.[22]

Since all the transplantation antigens of the skin are also present in the lymphocytes, the chimærical patient with Hodgkin's disease should show some degree of tolerance to maternal skin.

METHOD

Five male patients with Hodgkin's disease were homografted with maternal skin. The technique was as described previously,[23] except that the split-thickness donor skin was cut

TABLE I—DATA ON 5 CASES OF HODGKIN'S DISEASE IN WHICH HOMOGRAFTS WERE APPLIED

* Cyclophosphamide

free-hand from the upper lateral thigh of the maternal donor The grafts that showed prolonged gross survival were serially biopsied and stained by the Feulgen technique and hæmatoxylin and eosin. The biopsy specimens in case 3 were fixed in 10% formalin and those in case 4 in alcohol formol acetic acid (Davidson's solution)

RESULTS

The gross survival-times of the maternal skin, and the survival-times of unrelated skin grafts previously applied, are shown in table I The treatment received by these patients is shown in table II, and the proportion of female chromatin marker in biopsy specimens in table III

Two of the five patients showed prolonged survival of the maternal homografts In case 3 the Feulgen preparations were of poor quality and the female marker material was present in only 1–3% of cells, but serial biopsies in case 3, stained with hæmatoxylin and eosin, showed decline of the initial inflammatory reaction followed by intense lymphocytic infiltration at the time of gross rejection (140 days), indicating that the original graft was being rejected at this time In case 4 a high proportion of female chromatin-positive cells in all the biopsy specimens, indicated survival of the maternal graft

DISCUSSION

Homologous disease and Hodgkin's disease have the following characteristics in common weight loss, skin manifestations, hæmolytic anæmia, and in certain cases unexplained death Kaplan and Smithers have also noted these similarities [24]

TABLE III—DURATION OF MATERNAL-SKIN HOMOGRAFTS AND PROPORTION OF FEMALE CHROMATIN MARKER IN BIOPSY SPECIMENS

* Maternal skin obtained at time of homografting the patient.

Unfortunately, the temperature of animals with homologous disease has not been reported The lymphoid atrophy in homologous disease is often preceded by hyperplasia and granuloma formation with increase in weight of the liver and spleen [25,26] The absence of frank homologous disease in the "potential" patient with Hodgkin's disease can be explained by the very large "antigen" excess in relationship to the small amount of postulated homologous lymphoid tissue which is initially present.

The apparently long survival of lymphocytes judged by isotopic marker techniques has been given two interpretations One is that the lymphocyte itself survives intact for long periods The other interpretation is that it is not the entire lymphocyte, but only "chunks" of desoxyribonucleic acid (D N A) that survive for a long time, and that these "chunks" of D N A are reutilised to form new lymphocytes Morphological [27] and theoretical [28] evidence for this last hypothesis has been advanced If this second interpretation is correct, and if maternal lymphocytes do gain entrance into the fœtus, then the lymphocyte D N.A of the fœtus can itself become chimærical, being composed of the D N.A of the mother and also of the fœtus

Some of the murine radiation chimæras developed lymphomas which were composed of the donor-strain lymphocytes [21] If donor (maternal) lymphocytes could become malignant in patients with Hodgkin's disease, this disease could be treated with polycylic tumour-inhibiting (T I) hydrocarbons [17,18] These are effective against tumours only where some histocompatibility difference exists between host and tumour Green has reported preliminary favourable results with T I compounds in patients with Hodgkin's disease.[29]

We are well aware of the several possible explanations, besides acquired tolerance, of long-continued survival of maternal skin in patients with Hodgkin's disease In a previous study, however, in no case of Hodgkin's disease did unrelated skin survive for more than 34 days [23],

many of these patients were critically ill and had received extensive treatment Many more patients with Hodgkin's disease will have to be grafted, some with maternal skin and some with paternal skin Also, data concerning the survival of maternal-skin homografts in healthy people as well as patients with other chronic illnesses will have to be obtained The validity of the present hypothesis can be investigated in other ways as well We hope that this report will act as a stimulus for further studies

We acknowledge the technical assistance of Miss Nancy Whitehead We wish to thank Dr H Stambaugh, Dr M Lewin, and Dr M Flynn for performing the skin grafts on these patients, and Dr J Wolf, Dr P Cooper, and Dr T Spaet for their cooperation and support

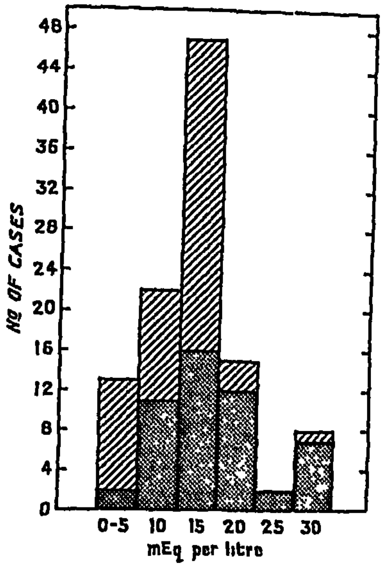
SERUM FATTY ACIDS AFTER FATAL HEART-ATTACKS

MANY fatal heart-attacks, while demonstrably due to ischæmic heart-disease, present no recent morbid-anatomical changes in myocardium or arteries to account for the sudden stoppage of the heart's action In a survey in which clinicopathological enzyme tests were used to elucidate the nature of these attacks, blood-lipids were examined also In 50 fatal cases of ischæmic heart-disease and 57 control subjects the simple colorimetric method of Stern and Shapiro[1] has shown serum-fatty-acid levels which may have a bearing on the mechanism of these heart-attacks

In this series four pathological groups were separated without prejudice to possible interrelationships They are (*a*) simple coronary atherosclerotic narrowing or occlusion, (*b*) fibrosis of the myocardium without recent change or thrombosis of the arteries, (*c*) myocardial necrosis whether or not accompanied by coronary thrombosis, and (*d*) cases in which an arterial thrombus was demonstrated without naked-eye evidence of recent myocardial changes

The mean normal value for serum fatty acids by Stern and Shapiro's method in young healthy adults is about 10 mEq per litre In the four groups described above the mean values were (*a*) 14 2 mEq per litre (27 cases), (*b*) 12 6 mEq (6 cases), (*c*) 15 5 mEq (11 cases), and (*d*) 16 1 mEq (6 cases) The mean value in these 50 cases was 14 7 mEq per litre, whereas the mean for the 57 controls was 9 9 mEq The difference between these means is highly significant ($t = 6\ 1$, $p < 0\ 001$) The controls were further divided into nine disease groups of which only two were suggestively abnormal, both yielding low values These were the cancer group (10 cases), with a mean of 7 5 mEq per litre, and the group of cardiac deaths not due to coronary-artery disease (12 cases), with a mean of 8 4 mEq

When the distribution of the results is examined (see figure), it is seen that 10 out of 11 values higher than 17 mEq per litre are from cases of cardiac ischæmia The 1 control with a high value was a patient with a pelvic abscess who had died from carbon-monoxide poisoning Furthermore, the values in the cardiac-ischæmia cases show a diphasic distribution whereas the controls are approximately normal in distribution 5 of these 10 high values belonged to the group dying from simple coronary occlusion



Distribution of serum-fatty-acid values from 107 cadavers

The solid columns represent values from 50 cases of ischæmic heart-disease, and the shaded columns the values from 57 controls

The level of serum fatty acids in cadavers is only slightly affected by decay

The mean values in successive 12-hour periods after death were 9 7 mEq per litre (17 samples), 12 2 mEq (35 samples), 12 7 mEq (20 samples), and 15 0 mEq (18 samples) The mean value during the period 4–6 hours after death (5 samples) was 8 8 mEq per litre Thus there was a slow rise starting soon after death These figures exaggerate the rise, since the cancer cases, which had low values, were mostly examined in a hospital mortuary soon after death, while cases of sudden death were examined in the public mortuaries rather later Even so, because the difference in the mean values attributable to differences in the mean time of examination between the deaths from cardiac ischæmia (43 5 hours) and the remainder (37 hours) is only about 0 6 mEq per litre, this cannot account for the significant differences recorded above After 48 hours the mean serum-fatty-acid level fell slightly (10 9 mEq per litre, 13 samples) and after 60 hours it rose again (14 0 mEq , 4 samples) This dip at the end of the accumulation curve is characteristic of several organic substances in cadaver blood, having been seen with hæmoglobin, phenolic substances, and the changes in opacity of deproteinised serum to ultraviolet light[2] In a large series, this reduces further the mean change due to time after death, and therefore undue regard need not be paid to this change

There was no significant difference between the mean ages of the cardiac-ischæmia group (65 years) and the control group (63 years)

The condition commonly recorded on death certificates as " coronary occlusion " is probably a syndrome in which several different factors may be the cause of the fatal insufficiency The high serum-fatty-acid values encountered in this series of cases of ischæmic heart-disease, their similarity to those from cases with recognisable recent organic changes, their dissimilarity from most of the control values, and, particularly, their diphasic distribution suggest that high levels of serum fatty acids may be one of these factors A larger series will enable the effects of selection to be excluded with greater certainty, and it remains to be seen whether any particular fatty acid is regularly responsible for the high values shown by the non-specific colour reaction of Stern and Shapiro's method

This work is supported by a grant from the North East Metropolitan Board research fund

Medical Societies

AMERICAN SOCIETY OF HÆMATOLOGY

THE second annual meeting of this society was held in St Louis Missouri, on Nov 22-24

Antibody Synthesis

Dr Herman Eisen (Pennsylvania), who also presented the views of his colleague, Dr Fred Karush, said that the two possible modes of antibody formation were the "instructive", requiring the presence of the specific antigen for the formation of specific antibody, and the "selective", which implied the prior existence of specific antibody-forming cells, the "clone" of Macfarlane Burnet. The qualities of a protein molecule, in one or more of which specificity must reside, were aminoacid sequence, helicity, the folding of the helix, and degree of polymerisation. There was at present insufficient evidence to indicate which theory was correct and which qualities of a protein antibody conferred specificity

Dr D W Talmage (Colorado) inclined to the selection theory, which implied that specific antibody formation was determined spontaneously and that corresponding antigen stimulated synthesis by, and probably reduplication of, the cell carrying this "natural template" Studies of tolerance and immunity suggested, on this theory that any antigen must have opposite effects on its corresponding clone at different stages of the latter's development.

Dr E S Lennox (University of Illinois) had developed a technique for the determination of antibody production by single cells, using lymph-node cells immunised to various bacteriophages, suspended in droplets, and assaying the power of these cells to inhibit phage activity About 20% of single cells could make two antibodies contemporaneously What appeared morphologically to be lymphocytes were only about half as active in antibody production as what seemed to be plasma cells, but such characterisation was not conclusive, for the cell types might not be stable and in these experiments were not quite "caught in the act" From these findings Dr Lennox argued against the selection theory, though the possibility that a single clone might be capable of producing more than one specific antibody could not be ruled out.

Dr A. Coons (Harvard) discussed rate of antibody production in primary and secondary response. Burnet and Fenner had shown that rise in antibody titre in the secondary response was almost logarithmic, and Dr Coons and his colleagues therefore examined lymph-nodes during both types of response, using a fluorescein label to demonstrate the presence of antibody in cells There was scarcely any labelling after primary antigen injection, after a second injection many more cells stained up, though none contained much antibody The positive cells in the node were not clumped in a clone Further experiments were then done to determine whether, in mice the time between primary and secondary antigen inoculation was directly proportional to the size of the secondary response The secondary response levels off, however, after about 20 days, and Dr Coons speculated that the continuing presence of antigen was required for the clone to continue to multiply At this point discussion arose as to why animals could not be converted almost exclusively into antibody It was assumed that at a critical level further antigen was prevented by antibody already present from exerting a stimulus to further antibody formation.

In a comprehensive review of immune tolerance and autoimmune disease Dr R. E. Billingham (Pennsylvania) speculated on the late breakdown of immune "tolerance" as a basis for autoimmune disease. Normally maintained "physiological quarantine", as in the thyroid, might break down, or late maturation, as in the breast or testis, might occur, so that tolerance might not have been acquired, or perhaps some lymph tissue might exist in a state of "quarantine", possibly in the thymus, and constitute a threat to earlier acquired tolerance In comparing the ability of cells of various origins to produce "tolerance" on the one hand, and "runt disease" on the other, Dr Billingham stressed that both the type of cell and the numbers in the inoculum were important. Lymphocytes seemed to be effective in producing both phenomena, but thymus cells might produce "runt disease" but not "tolerance"

Ætiology of Leukæmia

Dr Joseph Beard (Duke) followed his own aphorism that "people get up to talk about human leukæmia and the first thing you know they're talking about mouse or chicken leukæmia" He had found what he felt must be virus particles in thin sections of blast cells in acute human leukæmia observed with the electron microscope in only 1 case in 12, whereas Dmochowski in Houston had 50% positives In fowl leukæmia, however, no virus particles were seen either, unless the blast cells were grown in culture, when they became loaded. Dr Ludwig Gross (New York) pointed out that virus might not always show up under the electron microscope and what did show up might not be virus Dr S Schwartz (Chicago) developed his theme that variations in incidence of induction of leukæmia, using material from patients with leukæmia, might be due to different balance between virus and inactivating factors

Radiation as a factor was discussed by Dr Eugene Cronkite (Brookhaven) He presented arguments against interpreting any data at present available as showing that irradiation was leukæmogenic. He seemed not to be wholly convinced by his arguments himself, and finally agreed that at present a policy of playing safe was probably the best working basis

Dr Robert Heyssel (U S Public Health) presented the most recent figures for the incidence of leukæmia in the Japanese atom-bomb areas The errors in assessing dosage of radiation were recognised as being very great, and there was clearly much divergence of opinion about the significance of conclusions which have been drawn from earlier figures

Dr George Wooley (Sloan-Kettering Institute) summarised what is known about chemical and hormonal factors in leukæmogenesis in animals, emphasising the importance of the thymus for induction of leukæmias and tumours, and mentioning Metcalf's claim that a lymphocyte-stimulating factor (L.S.F.) was found in plasma of mice which later developed lymphoma. Dr J Trentin (Houston) mentioned that rises in L.S.F. had been observed after irradiation and he postulated that L.S.F. could be the mediating agent for leukæmia.

The epidemiology of human leukæmia was then briefly discussed, and the point was the need for good studies in this field. At this stage the chairman, Dr Jacob Furth (Roswell Park), took a show of hands of those who believed that a virus, radiation, hormonal and chemical factors, or genetic factors had been a causative factor in any one of their cases of leukæmia. Of a total of about 600, 26 raised their hands for radiation, 15 each for chemical and genetic causation, and viruses came a poor fourth

Notable among other contributions was a group of observations on transformation of human leucocytes into histiocytes, fibroblasts, and fat cells in subcutaneous diffusion chambers made of 'Micropore' Dr N L. Petrakis (San Francisco) showed pictures of his preparations with collagen fibres forming in chambers in which only cells from the buffy coat had been placed.

Dr E. Donnall Thomas' group (Cooperstown) had been studying hæmoglobin synthesis in fœtal tissues It seems that adult hæmoglobin is formed from the earliest period (about 9 weeks) onwards and that all organs producing hæmoglobin produce both the adult and fœtal type in proportions constant for the particular tissue.

Dr S Piomelli (Boston), in studying "secondary disease" in X-irradiated rabbits, transfused with homologous bone-marrow, found that transfusion immediately after irradiation was life-preserving, 12 hours later it was ineffective Incomplete red-cell antibodies were found in the serum of the runts so produced, with a positive Coombs test 3-7 weeks later Red-cell survival in these animals was always reduced but full-blown secondary disease was rare and less severe than in rodents Since rabbits are not pure-bred these results were considered encouraging. Dr W. HOLLANDER (*Oak Ridge*) pointed out that mice with spleen-induced " runt disease " have a leucopenia but not a positive Coombs test

Dr. W. DAMESHEK (Boston) and his colleagues presented data showing that so far no success has been obtained in the treatment of aplastic anæmia with bone-marrow transfusions

Reviews of Books

Medical Surveys and Clinical Trials

Editor L J WITTS, C B E, M A, M D, SC D, F R C P., Nuffield professor of clinical medicine, University of Oxford London Oxford University Press 1959 Pp 328 35*s*.

Professor Witts has collected the experience and outlook of many experts on population surveys, follow-up studies, and therapeutic trials His co-authors are all well known and their contributions are of great interest. All who wish to undertake such large investigations should consult this book, which indicates both the value and the difficulties of population surveys The widespread and proper use of statistical method, so desirable, is not always easy to achieve, and often enormous numbers of subjects have to be studied before an answer becomes clear Almost everyone has been impressed by the statistical evidence which proved the value of streptomycin in pulmonary tuberculosis, which linked cancer of the lung with *cigarettes, and maternal rubella with fœtal abnormalities* but these were all elaborations following strong clues from previous clinical observation and experience A well-known survey of blood-pressure in a population led to much controversy and revealed the difficulties of tackling a problem by survey *methods alone The question seems to have been clarified by* the application of knowledge based on extensive clinical and pathological experience, and once again the professional habit of dividing normal from abnormal systolic blood-pressure at about 160 mm Hg appears to be reasonable In short, the statistical approach may be quite unintentionally confounding unless regulated by strict attention to the existing body of knowledge Even " high statistical significance " is not proof, unless the idea finds other scientific support

The survey method is often extremely costly from its very magnitude, and sometimes the problems posed are capable of solution by precise laboratory methods on much smaller numbers The open mind free from bias, beloved of the statistician, can conceal medical amateurishness or even ignorance, while the good clinician is discouraged from detailed observation and questioning by the requirements of " double-blind " trials Subjective judgments inevitably come in, and in one blood-pressure survey in Bergen there was an obvious inclination to record the pressures in the nearest round figure *Observer error in all clinical matters is a* well-recognised phenomenon, and if we could believe all that has been written about it, it is amazing that diagnosis is as satisfactory as it seems to be in practice In large population surveys complete individual case analysis is impossible and records are often made of some single measurement or parameter If our predecessors of the year 1800 had surveyed " anæmia " based on hæmoglobin only, what light would have been cast on blood disorders? More recent attempts to define a mutation-rate in hæmophilia become of little value as we realise the number of concealed cases with only slight reduction of antihæmophilic globulin Thus the modern view drives us back to the laboratory work of the scientists for inspiration and guidance Without the backing of a well-founded idea, surveys are apt to be sterile, and the best statisticians cannot extract the answers

One or two of the contributors to this monograph pay little attention to the laboratory approach the editor himself says " the location of clinical scientists in hospitals . invites th danger of an increasing impoverishment of ideas muc current research is trivial in conception " This is a challeng which many will find provocative All who are interested i surveys and particularly those who imagine they are eas ways to dramatic conclusions should read this book and tak warning.

Aldosterone in Clinical and Experimental Medicine

E J ROSS, M D, PH D, M R C P, senior lecturer in medicine *University College Hospital Medical School, London.* Oxford Blackwell Scientific Publications 1959 Pp 144 22*s* 6*d*

ALDOSTERONE was discovered only five years ago and is still and likely to remain for some time, the focus of much research It has attracted interest in many countries because its role in controlling electrolyte metabolism is of concern to biochemists, physiologists, and clinicians Dr. Ross, who has worked in Dr George Thorn's laboratories at the Peter Bent Brigham Hospital in Boston, is in a strong position to discuss aldosterone from every possible aspect, and he does so very ably in this concise monograph

From a basis of 539 references he discusses all that is known about the hormone, and he has done a great service to all kinds of workers in this field by his review of the extensive literature. *He writes clearly and factually, and it is not until the last* chapter, on the role of aldosterone in human homœostasis, that he allows any speculation Dr Ross is not afraid to say what is not known and to point the way for future research.

This book is an excellent summary of the position at half-time We hope Dr Ross will be able to report the outcome of the *game when the final whistle is blown*

The Principles of Humane Experimental Technique

W M S RUSSELL, M A, D PHIL, UFAW research fellow, department of zoology and comparative anatomy, University College London, R L. BURCH, hon UFAW research assistant, London Methuen 1959 Pp 253 30*s*

THE object of this book, sponsored by the Universities Federation for Animal Welfare, is to ensure that experiments on animals involve the least possible inconvenience to them, while increasing the scientific value and reliability of those experiments which are performed

The authors summarise the matters to which they draw attention as follows (1) belated knowledge of the relative numbers of species used, (2) persistent use of the Friedman test, (3) delay in the initiation of microbioassay, (4) delay in the exploitation of statistical methods, (5) delay in the rationalisation of breeding methods for uniformity, (6) delay in noticing published effects of environmental factors, (7) delay in the application of psychosomatic principles, (8) conservatism in the choice of laboratory species, and (9) the guarded approach to several aspects of toxicity testing These are all questions of moment to the research-worker, who, however, it should be said in justice to him, recognises them all

The authors have presented their work as if it were a review article, and have copiously burdened the text with references, most of which are not likely to be challenged by the reader of a book of this type For this reason it may fail to reach the audience to which it is directed Its purpose is admirable, and its matter unexceptionable But it is not easy reading a shorter and more dogmatic paper would have made a stronger impact, and lost none of its authority

---

Pharmacopœa Internationalis (*Supplement* Geneva World Health Organisation 1959 Pp 224 25*s* Obtainable from H M Stationery Office, P O Box 569, London, *S E 1*) — The first edition of the *International Pharmacopœa*, volumes I and II of which appeared in 1951 and 1955, is completed by this supplement containing a further 94 monographs and 17 appendices

THE LANCET

LONDON 2 JANUARY 1960

Into the '60s

> "He who plays a part in events is the last to know their real importance, and the moment he tries to seize their purport, and to take a conscious part in them, his actions are barren of result."

Describing the situation after the fall of Moscow in 1812, Tolstoi wrote of the uselessness of people who tried to understand what was going on, compared to the usefulness of the army, which did not trouble its head with large affairs but continued to think about "the next quarter's pay, the next halting-stage, of Matrechka, the vivandiere, and so forth."[1] Similarly in Medicine one may argue that the only useful thing is to get on with the job—with the good work that will make all the difference to some individual patient or (if an investigator has luck or genius) may transform the outlook for thousands or millions, as happened through the discovery of penicillin and streptomycin.

But Tolstoi overstated his case. Few armies remain long in the field unless there is at least enough intelligent planning to ensure that they receive their pay, their food, and their ammunition, and few armies win battles unless arrangements are made for them to be in the same tract of country as the enemy. In the war on disease the same is broadly true, and, because this war becomes steadily more elaborate, we cannot avoid more organisation of one sort or another. We all know, of course, that what ultimately matters in Medicine is the care of the patient and the prevention of disease, but the kind of organisation matters greatly, too, because a defective one will not supply the medical troops with what they need and will not deploy them where they are wanted most. In this country our biggest attempt at medical organisation—the National Health Service—has not proved nearly so restrictive as many of us feared, but it is not yet as constructive as some of us hoped: it has preserved most of what we valued but it has failed to add what we might value more. On the performance of its difficult first decade, the mark it deserves is perhaps an Oxford β (opinion will differ on whether a β— or a β+), and the question to be decided in the '60s is whether the burden of routine will keep it at this merely respectable standard or whether it will achieve the α of which it is capable. To do so it needs, of course, more money, but it also needs more of the rare kind of discontent that gets things done. In the '60s scientific Medicine is likely to accelerate its startling progress, and at all levels we shall need corresponding flexibility and enterprise. Considering the difficulties, our service is good and economical, but the public will still have bought it too dear if, under Government auspices, it loses the adaptability which is a sine-qua-non for biological success in a changing environment.

Some of our present problems are those of the particular kind of organisation we have created. For example, something will sooner or later have to be done to make the Ministry of Health less like an ordinary Government department and more like the nerve-centre of a complex public and professional service. (The Government so far shows no sign of having read the Acton Society and Sir George Schuster[2] on this far from negligible subject.) Something will have to be done, too, to bring the English regional hospitals and the teaching hospitals more closely together, in the interest of both. (Probably the time has come to begin an inquiry into the size of the regions, the function of regional boards and hospital management committees, and the simplification of their administrative machinery.[3]) Again, something will have to be done about remuneration in the health service—"the next quarter's pay"—on which the Royal Commission should be reporting at the end of February. But beyond such local and relatively soluble problems are more universal and intractable ones arising mainly from the rapid industrialisation of medical work. For instance, even in the prosperous United States, a great many hospitals find it as hard as many of ours to maintain a proper junior staff. Far more important, the future of personal medical care remains uncertain everywhere except in those Communist countries where the general practitioner has been frankly abolished in favour of the small specialist team. Scarcely anywhere, as yet, does the prevention of disease get as much attention as its treatment. And in Medicine, as in international relations, there is an ever-increasing risk that uncontrolled science will neutralise humanity.

In the past decade we in this country have been making the overdue transition from a commercial type of medical practice to one in which the patient's needs can be considered first, last, and all the time. That in itself is an achievement, and one in line with professional tradition. Furthermore, whatever we may feel about our national deficiencies, monetary or mental, we still have in Britain an exceptionally favourable environment for practising and improving and enriching medicine. Our country is geographically small but intellectually extensive, and its political stability is such that it can accept considerable changes without disruption. Unhappily, with that innate respect for the past which the past, as a whole, so seldom deserves, many members of our profession, both old and young, are inclined to underestimate the current British contribution to Medicine. The truth, however, is that though there are some things we cannot do, there are many—both scientific and social—which we do better than anybody else. From those individual pursuits and personal preoccupations which Tolstoi commended we can still confidently count on our quota of discoveries—usually no more than tiny points of light, but just occasionally some great flash And likewise from a certain national ingenuity in that art of organisation which Tolstoi was inclined to underrate, the public can expect further benefit because good organisation promotes good use of new knowledge

[2] See *Lancet*, 1959, i, 349.

[3] *ibid* 1958, ii, 27.

If one may judge by what happened in the first six decades of this century, nobody need fear lack of incident or interest in the seventh Least of all, perhaps, anybody with insight into diseases and health, and a liking for the people who have them

Genesis of Cardiovascular Murmurs

The presence of a murmur does not depend on any vital property of the heart or blood-vessels Its primary cause is an alteration in the nature of flow of the blood itself, the solid structures forming the boundaries of the fluid are thrown secondarily into a state of greater or lesser vibration These conclusions, set out by Corrigan[1] for these columns some years ago, have not been seriously challenged

Corrigan pointed out three anatomical conditions which tend to give rise to murmurs constriction of the lumen of a vessel, a constricted orifice leading to a normal cardiac chamber or vessel, and a normal orifice opening into a dilated chamber or vessel For such murmurs, and for the murmurs of high-output states and those accompanying abnormal anatomical communications, the altered character of flow may be turbulent[2] (fluid particles moving at random), more or less orderly with the production of eddies (vortices),[3] or associated with a periodic vortex-ring pattern[4] (musical jet) or with the formation and collapse of bubbles of dissolved gas or of water vapour (cavitation)[2]

In a long uniform cylindrical tube, turbulence develops in a homogeneous fluid flowing at a constant rate when the Reynolds number VD/ν (velocity × diameter/kinematic viscosity) exceeds 1900[2] The corresponding critical Reynolds number for blood is 1940 ± 160[5] Reynolds[6] noted that with varying flow, and with steady flow in a channel which converges or diverges or which has a rough wall or non-circular section, the critical velocity associated with the onset of turbulence is not necessarily determined by this function VD/ν McDonald[7] doubts whether turbulence is as important a source of murmurs in the cardiovascular system as was once held, and now Bruns[8] has expressed the view that the acoustic energy generated by turbulence is inadequate to account for audible murmurs Although he describes various ideas in support of this view, the evidence—particularly on the interaction between a turbulent fluid boundary layer and a vessel or cardiac wall—must be regarded as incomplete

The existence of eddies or vortices (generated, for example, by an obstruction in the path of flow) may be causally related to murmurs[7] since a considerable pressure drop may exist in their centres Bruns[8] discusses the analogous phenomenon of Æolian tones[9, 10] (a familiar example of which is the singing of wires in a wind), and the associated rhythmic shedding of eddies[11] which stem from a cylindrical wire placed in the path of a constant flow of air These have been studied extensively[12–15] Such eddies in a fluid medium consist of localised spinning masses of fluid, these pass downstream for some distance before dispersing The rate of development of eddies is more or less regular, and since this generation occurs alternately from each side of the obstacle, two rows of vortices are formed downstream Sound is emitted from such a wake, and the frequency or pitch of the tone corresponds to the rate of shedding of vortices[8] This frequency is proportional to the ratio of the fluid velocity to the diameter of the cylindrical wire[10] Slight irregularities of form of the cylindrical wire give rise to a frequency spectrum of sound—i e, noise[8] Bruns draws attention to the movement of the bulk of fluid comprising the wake, rather than the vortices themselves, as the source of acoustic power Similar sounds have been noted from the wakes generated by vanes in flowing water[16]

The rhythmic disturbance of an axially symmetrical jet, associated with the formation of ring-vortices,[17] is a related phenomenon[18–20] Savart[20] in 1854 described a loud tone heard when a jet of water issues from a small orifice into air or water The frequency of generation of ring-vortices from such an orifice is related to the velocity in a somewhat stepwise fashion,[20] or, more generally, to the Reynolds number,[21] and tends to increase with increasing velocity or diminishing jet diameter The same vortex pattern develops for larger orifices, even those almost filling the lumen of a vessel[8]

Considerations of acoustic energy,[7, 8] of the frequency, intensity, and transmission of particular cardiovascular murmurs,[8] and of Kármán's classical theory[13, 22] of "vortex streets" point to the importance of such eddies in the production of murmurs The low pitch of downstream-propagated murmurs (of mitral stenosis and aortic stenosis, for example) and the higher pitch of upstream-propagated murmurs (of mitral insufficiency) are compatible with this concept[8] The model experiments of Bruns are in some respects confirmatory, for example, the intensity of low-frequency components of the murmur generated by a constriction in a vessel increases at first as the stenosis is made smaller; but for very small orifices the intensity falls off again, as predicted by Bruns on the basis of vortex theory

Euler[23] foreshadowed the importance of cavitation in hydraulics in 1754 Reynolds cavitation[6 21 25] associated with fluid flow through a constriction is unlikely to be a common source of significant cardiovascular sound since the pressure differential required across the stenosis (about 350 mm Hg) is rarely achieved)[8] Gas-entrained bubbles would emit frequencies above the important components of most murmurs[26] Nevertheless, the possible existence of a different form of cavitation[7] associated with the low pressures at the centres of vortices cannot be disregarded

The clinical importance of understanding the mechanism of genesis of murmurs was recognised by **Corrigan** Clearly the story is not yet complete Meanwhile we should recognise the fallacy of simply equating turbulence with murmur production, the need for considering further the consequences of the pulsatile character of flow, and the interplay between the primary disturbance in the blood and the secondary disturbance of the boundaries

A New Familial Abnormality of Red Blood-cells

In the past few years information has been accumulating about an entirely new type of intrinsic abnormality of red blood-cells—an enzyme deficiency which is usually harmless unless the cells are exposed to one of several drugs or ingested substances[27] The existence of this defect was discovered during an investigation of the acute hæmolytic anæmia caused by primaquine—an 8-aminoquinoline drug, chemically similar to pamaquin, used for the treatment of malaria Cases of this anæmia caused by pamaquin had been described by **Manson-Bahr**[28] in 1927, by **Cordes**[29] in 1928, and by many others later The patients were extensively investigated by current techniques, but the results were negative no constant immunological abnormalities were detected, there was no abnormality of red-cell fragility and no sickling, and there was no correlation between the plasma level of pamaquin or primaquine and the degree of hæmolysis But there were some positive observations In a sensitive patient primaquine always induced hæmolysis except for a time after a dose, during which further doses did not cause hæmolysis Primaquine sensitivity is not common, but it is relatively more frequent among Negroes, and British troops have been observed to be less susceptible than Indians or Burmese The clinical course of the hæmolytic reaction is very characteristic In a susceptible person no evidence of hæmolysis appears for the first two to three days, and this latent period occurs whether primaquine is being given for the first or a subsequent time The signs include hæmoglobinuria, icterus, and a rapid decrease in red cells and hæmoglobin, reticulocytosis develops and **Beutler** et al[30] pointed out that Heinz bodies appear in many of the red cells The Coombs reaction for adsorbed antibodies remains negative The acute phase lasts about a week, and recovery ensues, even if the administration of primaquine is continued This apparent tolerance lasts for a few weeks after withdrawal of the drug, and another dose then produces exactly the same sequence of symptoms and signs **Beutler**[27] notes that some other drugs such as acetanilide, sulphanilamide, and nitrofurantoin cause a similar clinical picture of hæmolytic anæmia in susceptible patients

Such a drug-induced hæmolytic anæmia could be due either to the production in the blood of abnormal factors that affected red cells, or to some abnormality of the red cell itself In 1954 **Dern** et al[31] showed that sensitivity to primaquine was due to an intrinsic abnormality of the red blood-cells Red cells from a sensitive person were labelled with radio-chromium and infused into a non-sensitive person, primaquine (30 mg daily) was given to this non-sensitive recipient, and the labelled red cells were rapidly and selectively destroyed Conversely labelled red cells from a non-sensitive person transferred into a sensitive patient were unaffected by administration of primaquine The primaquine-sensitive cells were fully investigated by **Beutler**, **Dern**, and their co-workers None of the previously known red-cell abnormalities were present, and eventually investigation of the Heinz bodies provided the clue When sensitive red cells were incubated in the presence of oxygen with certain reducing substances, such as acetylphenylhydrazine and ascorbic acid, they developed a pattern of Heinz bodies—denatured protein particles—which was consistently different from that appearing in non-sensitive cells[32] **Beutler** et al described a test for detecting sensitive cells heparinised blood is incubated for four hours with a pH 7 6 phosphate buffer, containing 200 mg glucose per 100 ml and 100 mg acetylphenylhydrazine per 100 ml , wet preparations are stained with crystal-violet and observed under the microscope In a sensitive person more than 40% of the cells contain 5 or more Heinz bodies, whereas in almost all non-sensitive persons less than 30% of the red cells contain this number These findings have been confirmed by others and noted in some other drug sensitivities, and **Larizza** et al[33] found the same sensitivity in the red cells of patients with favism—the curious hæmolytic anæmia, well known in Sardinia and southern Italy, that develops in some who eat broad beans (*Vicia fava*) or are exposed to the pollen of the broad-bean flowers

The next step was the demonstration by **Beutler** et al[34] that the glutathione content of sensitive red cells tended to be below normal and that poisoning of non-sensitive cells with iodoacetate, which binds sulphydryl groups, caused them to react like sensitive cells in the Heinz-body test Later these workers found that when red cells from primaquine-sensitive patients were incubated for two hours with acetylphenylhydrazine the glutathione content fell sharply from a starting level of about 50–70 mg per 100 ml of red cells to less than 12 mg per 100 ml, whereas with cells from non-sensitive persons with a normal starting level of 50–80 mg per 100 ml the figure remained above 44 mg per 100 ml This observation has been developed into a "glutathione-stability test" by means of which red blood-cells affected by this abnormality can be readily detected[35] The glutathione content of red cells was determined by a modification of the colorimetric technique of GRUNERT and PHILLIPS[36] based on the development of a rose-coloured complex with sodium nitroprusside and its stabilisation with cyanide The reason for this instability of glutathione is thought to be an enzyme deficiency, BEUTLER et al[37] have carried out experiments that suggest that there is a deficiency of glucose-6-phosphate dehydrogenase, but other enzymes concerned with carbohydrate metabolism in the red cells may also be involved

The glutathione-stability test has been tried in many blood diseases, and in most the results are negative Positive results are, so far, limited to the hæmolytic anæmia induced by certain drugs in sensitive individuals and in favism The results with favism are of much interest, since it is known to be an inherited disease SANSONE and SEGNI[38] and LARIZZA et al[33] in Italy and SZEINBERG et al[39] in Israel found that the cells in patients with favism showed glutathione abnormalities like those in primaquine-sensitive patients SANSONE and SEGNI eventually found that in patients with favism the red cells gave positive results with the Heinz-body test and the glutathione-instability test of BEUTLER, and they showed a deficiency (often complete) of glucose-6-phosphate dehydrogenase These workers and others since have detected this enzyme abnormality of the red cells in apparently unaffected relatives of patients with favism, and the defect was shown to be less complete in females than males SANSONE concluded that the defect was inherited as a dominant partially sex-linked character CHILDS et al,[40] in Baltimore, have carried out an extensive genetic study of the probably identical primaquine-sensitivity of red cells

They selected Negroes for this study since the defect is known to be commoner among them than among the white population, and they used the glutathione-stability test for sorting In a group of 144 Negro males and 184 Negro females, the prevalence of sensitive individuals, or "reactors", was found to be about 14% in males and 2% in females, but in addition 5% of females showed partial or "intermediate" sensitivity Reactors were found in 16 families, and all cooperative members of these families were tested—90 females and 73 males The results showed again a preponderance of reactor males, but female reactors and intermediates together almost equalled the males Affected members were found in an many as three generations In family 1, for example, a female reactor was found in generation 1, but her husband was not tested, of her 5 children, 1 male and 1 female were reactors, the male married a normal female and had a normal son and a reactor daughter, this daughter married a normal male and had 4 daughters of whom 3 were intermediate reactors, 1 of these has married a normal male and had 6 children, all normal, in addition 1 of the apparently unaffected females of the second generation married a normal male and had an intermediate reactor daughter

CHILDS et al suggest that the most likely mode of inheritance is "sex-linkage with incomplete dominance", thus agreeing with the results from favism

Possibly other so far unexplained hereditary hæmolytic disorders may prove to be due to enzyme defects rather than to allergy or undefined immunological abnormalities Thus at the recent European conference in London Dr. T A J PRANKERD pointed out that an abnormality of glycolysis has been detected in the red blood-cells in hereditary spherocytosis, and a defect of phosphoglyceromutase has been found in the red cells of a family with the congenital non-spherocytic hæmolytic anæmia described by CROSBY[41] Such investigations are so far in the early stages But the Heinz-body test is easy to carry out, and the glutathione-stability test is feasible in any biochemical laboratory, and these tests should clearly be applied in patients with drug-induced hæmolytic anæmia or unidentified hæmolytic anæmia The workers who began to investigate once again the oddities of the hæmolytic anæmia induced by primaquine can hardly have anticipated that they would end by providing an explanation of favism There are still many curious facts to be explained about these anæmias, but these researches have notably advanced our understanding of them

Dental Drills

THE earliest dental drills were based on either the jeweller's bow drill or else the Archimedean drill, which resembled those used in fretwork The first power-driven drill was invented by G F HARRINGTON, who in 1864 patented a clockwork device which would run for two minutes on one winding[42] The treadle-driven foot engine was introduced by MORRISON in 1870–71 An electrically driven drill had been invented by G F GREEN in the 1850s[43], but this seems to have been little used In 1868 GREEN introduced a pneumatic engine in which the drill was "propelled by a certain mechanism" contained in the handpiece The first practical electric engine is supposed to have been made by the firm of Siemens-Schuckert, but the foot engine continued in use well into the 1920s

Nearly forty years ago it was decided on theoretical grounds that the optimum cutting speed was in the neighbourhood of 300,000 revolutions per minute (r p m) for a 1 mm ($^1/_{25}$ in) diameter bur or carborundum point, but no apparatus operated at such a speed, which is the equivalent of a linear speed of 12–15 metres (37–46 feet) per second Until about 1943, when diamond cutting instruments were introduced, the maximum speed of most dental engines was about 4000 r p m Tungsten-carbide burs came into production soon afterwards, and they, too, were found to cut better at higher speeds Walsh and Symmons[44] reported that high rotational speeds reduced unpleasant vibration, and this observation was confirmed by Ingraham and Tanner,[45] who also noticed that tension, and consequently fatigue, for both operator and patient diminished at speeds over 6000 r p m Walsh and Symmons[46] found that the most unpleasant vibrations were those generated at rotational speeds between 6600 and 9500 r p m There is little advantage in increasing speeds from 26,000 to 45,000 r p m , but at speeds from 45,000 to 100,000 r p m there is a spectacular increase in cutting efficiency, which becomes twenty to thirty times that at 4000 r p m[47] The cutting rate of an ordinary steel bur continues to increase with speeds up to 10,000 r p m or thereabouts, diamond instruments perform best at 60,000–80,000 r p m , while the cutting power of tungsten-carbide burs continues to increase with speed up to the maximum at present obtainable In 1953 Nelsen et al[48] described a 61,000 r p m hydraulic turbine handpiece, and two years later McEwen[49] described a belt-driven handpiece which attained a rotational speed of 200,000 r p m , at this speed the vibration frequencies were beyond the threshold of perception, and the cutting efficiency was far greater than any previously attained Air-turbine instruments were developed in 1956, these operate at rotational speeds of 200,000–300,000 r p m , and use small-diameter diamond or tungsten-carbide cutting tools Cavity preparation by a carbon-dioxide-propelled jet of aluminium oxide ("airbrasive" technique) and ultrasonic vibratory drills have been tried, but neither method has become popular

[43] Taylor, J A A History of Dentistry, p 135 Philadelphia, 1922

At high speeds, because only a light touch is needed to guide the bur, fatigue in the operator is lessened, and, with the almost fortyfold reduction in the amplitude of vibrations transmitted to the tooth, the whole procedure is much less trying for the patient This in itself encourages better dentistry, and often a great deal more can be done without recourse to local analgesia High-speed cutting, though more painful than the abrasive jet, which is the best-tolerated method of all, is nevertheless far more acceptable to the patient than conventional speeds[50] But what of the risks? The dental pulp may be injured during the preparation of the smallest cavity because of its susceptibility to both thermal and pressure changes Fortunately this damage is usually only temporary, but the higher the cutting speed and the deeper the cavity, the more lasting is it likely to be Since the introduction of "threshold" high speeds[50] (10,000–18,000 r p m) it has become usual to cool the tooth with either a jet or a spray of water during cutting The importance of adequate cooling has been shown by Vale,[51] who measured the temperature rise in the pulp chamber of an extracted tooth Using a diamond instrument at 3500 r p m , the temperature in the pulp chamber rose to 21°C above ambient, with water cooling, the rise was only 4°C A tungsten-carbide bur rotating at 17,000 r p m caused a temperature rise of 40°C, whereas with spray cooling it was only 9°C An air turbine with a diamond instrument, using air cooling alone, produced a temperature rise of 16°C, compared with zero when a water jet was used Some operators (and patients) have remarked on a smell of burning which often accompanies cutting in some instances incandescence of the enamel has been noted Whether this is just a surface effect, as is suggested by measurements of pulp-chamber temperature, or whether enough heat is generated to injure the pulp is uncertain, but a sandpaper disc rotating at 4000–5000 r p m can produce the same smell without any complaint from the patient Air turbines are not suitable for use with large-diameter cutting instruments—the linear speed of a cutting particle on a disc is too high, and the torque of the turbine too low Damage to the cells of the pulp[51] is a disturbing feature of high-speed cutting Cell disorganisation is known to develop at frequencies in the neighbourhood of 1 5 megacycles (10^6 cycles) a second, and possibly an air turbine running at 250,000 r p m could generate harmonics at this frequency Further research is needed into this point, and into the occasional disintegration of large portions of enamel probably this is due to microscopic flaws in the enamel, or else to the tooth coming into resonance with the natural frequency of the cutting instrument or some harmonic of it

Even its most enthusiastic advocates cannot deny that the air turbine is noisy, and that its high-pitched whine carries some distance Surprisingly, the patient is usually the last person to complain of this[50], airborne noises apparently cause less distress than those conducted through bone Kilpatrick[50] suggests that the surgery be lined with acoustic tiles, and music played through insert-type earphones to soothe the patient Gardner and Licklider[52] have recommended the use, besides music, of a random noise, consisting of a strong, low-frequency component combined with a weaker and higher-frequency one Fear has been expressed that continual exposure to the high-pitched note of the air turbine may injure the ears of the operator—though no such injury has yet been observed One manufacturer has reduced the noise by returning most of the exhaust air to the cabinet of the machine Because of the high frequencies involved, a very small built-in silencer near the rotor of the turbine should eliminate much of the more unpleasant noise, but this does not seem to have been tried The small ball races in the handpiece contribute a fair amount of mechanical noise, and silencing these presents greater difficulties Disquiet has also been felt at the force with which particles of tooth substance and pieces of old filling material are propelled into the air by the blast of the turbine exhaust For the patient this is unlikely to be a serious hazard, but the operator might be well advised to wear some form of mask An aspirator, more efficient than the usual water-operated saliva ejector, is essential, high-velocity suction apparatus is already on the market in the United States [50] A further hazard concerns the oil which is entrained with the air-supply to lubricate the turbine The amount of oil used is small (15–30 drops a minute), but it is disturbing to see that one turbine is advertised as using liquid paraffin the use of vegetable oils might be attended by less risk There have been rumours of turbines disintegrating, but no instances of this have yet been published, and, in any event, the head of the handpiece would probably be strong enough to contain the fragments

Whatever its disadvantages, the high-speed drill is a notable technical advance It will probably never supplant altogether the conventional electric engine, but when it is used it will make cavity preparation less tiring for the operator and less unpleasant for the patient

Annotations

WHAT TO EXPECT FROM OUR BABIES

IT may come as a surprise to many that hitherto there have been no accepted weight standards for infants in the first year of life according to birth-weights Without exact information it has seemed reasonable to suppose that most of the smaller infants at birth would at older ages remain at the lower end of the normal weight-range, but this is disproved by Levin et al in a study, published by the Medical Research Council,[1] of 521 healthy full-term and 223 premature London infants

The figures for full-term infants agree closely with those already defined by workers in this country and the U S A Greater interest attaches to the weight records of the premature infants, for these show the overriding influence of an inborn pattern of body size towards which growth proceeds, regardless of accidents such as gestational age at birth Thus, Levin et al find that the mean rate of weight-gain of premature infants was equal to that of infants of comparable age from conception who had remained in utero until term A similar association between gestational age and mean gain in weight during the early months was found in the smaller babies compared with the larger babies with weights above $5\frac{1}{2}$ lb at birth (all of whom are traditionally regarded as full-term), the smaller infants having the greater mean increments of weight in their first year In fact, at the end of this time there was a difference of only 10 oz between the mean weights of male infants with birth-weights of 6–7 lb and of 9–10 lb

A physiological standard of growth based on gestational age was suggested by previous assessments of fœtal gain in the later months in utero [2,3], and this was put to the test on a small scale by Young et al [4] There is now little doubt that the standard weight curves for full-term infants can be applied to premature infants by correcting for their age from conception, gauged by birth-weight For example, using Levin's standard curve, the correcting factor for infants weighing $2\frac{1}{2}$ lb at birth is $2\frac{1}{2}$ months, so a 5-month-old infant with this birth-weight should be compared with the full-term standards of 5 less $2\frac{1}{2}$—i e, $2\frac{1}{2}$—months On the same basis healthy infants who have a higher than average birth-weight should be regarded as postmature

The weight gains of the premature infants in the series were high in comparison with published figures,[5] reflecting a successful plan of nutrition Most were artificially fed partly or completely, but all the smaller ones received human milk in the first one or two weeks until feeding habits were well established, and a small group under $4\frac{1}{2}$ lb were fed on breast-milk alone until they were 8 weeks of age Between 2 and 8 weeks of age the weekly mean gains in weight of this group were lower than those of comparable infants given cow's milk mixtures at the same stage—a difference that has been previously recorded The lower gains can be attributed to the lower protein content of human milk, which has been calculated as insufficient to allow for the "normal" high rate of growth relative to body size between the 28th and 40th weeks from conception In contrast, the breast-fed and artificially fed full-term infants up to 5 months of age gained weight at equal rates, which is to be expected from the amount of protein in an ordinary supply of human milk at this time But, as Levin et al remark, breast-milk is unlikely to provide a satisfactory protein intake for a wasted full-term infant with a higher intake his weight might catch up more quickly with that appropriate for his size On the other hand, it is important to avoid prescribing the usual cow's milk mixtures, with their high protein and electrolyte content, for some infants in whom growth is slow or arrested, such as those with congenital cardiac or renal abnormalities, or those with acute illnesses due to infection (which includes many infants at one time or another before weaning age), otherwise the stress of a high excretory load may precipitate dehydration crises and electrolyte imbalance [6]—a point that is often overlooked in comparing the merits of artificial and of breast feeding Breast-milk is thus the best food for the infant born at term in health this enables him to grow at an optimal rate, and in disease it enables him to withstand phases of stress with the least possible disturbance of his internal milieu

The initial motive in collecting the clinical records of the infants was to provide a background for serum-protein studies These, too, were of special interest in relation to prematurity Analysis showed that, the lower the birth-weight, the lower the serum protein, albumin, and globulin levels at all ages from birth to 3–5 months Grouping the infants by age from conception, Levin et al showed that the serum-protein level corresponds with the maturity of the infant A single curve for infants of all birth-weights shows the changes with age from 28 to 92 weeks from conception This is a new approach which gives a clearer understanding of the changes with age, and now the significance of other variables may be more accurately assessed Several of these were investigated but were found to be without effect on the serum-protein levels, changes in weight were a more sensitive index of nutritional sufficiency

[5] Dunham, E C Premature Infants New York, 1955

[6] Kerpel Fronius, E *in* Colloquia on Ageing London, 1958

The report also contains sections on hæmoglobin levels, on serum-non-protein-nitrogen levels in relation to age and diet, and on γ-globulin levels in relation to age This valuable collection of data will be a useful source of standards for all concerned with the development of infants It will undoubtedly promote a more rational approach to the assessment of setbacks to growth due to either disease or dietary insufficiency

GASTRIC OUTLINE AND MOTILITY

THE normal stomach shows a wide range of outline and motility, but the descriptive terms applied to the outline—cup-and-spill, cascade, steer-horn, sthenic, and so on—and expressions such as hyperperistalsis and gastrospasm applied to its motility do not encourage understanding of why any one patient's stomach is as it is

The radiographic outline of the gastric cavity is a model of the mucosal outline, which changes from moment to moment as a result of movement of the mucosal layer on the innermost muscular coat, grosser changes in outline result from contraction of the muscle coats In the longitudinal part of the stomach contraction of the oblique muscle-fibres which form the innermost muscular layer produces a coarsely notched appearance of the greater curvature This feature is often accentuated in the presence of ulceration, and it terminates abruptly where the oblique fibres are replaced by the circular fibres as the innermost muscle layer, at the transition from the longitudinal to the transverse part of the stomach

In the normal stomach peristalsis begins near the cardia, and wave follows wave at a rate of about nine contractions a minute Though stimulation of vagal cholinergic fibres excites peristalsis, and stimulation of adrenergic sympathetic fibres decreases the rate, the pacemaker is probably spontaneous muscular contraction, since excised strips of muscle from the cardia contract at roughly the same frequency as the normal stomach Strong emotional stimuli of anger and anxiety increase the rate and depth of contraction,[1] and fear can temporarily interrupt peristalsis[2] The longitudinal and transverse portions of the stomach probably have inherently different contractile patterns By sectioning cats' stomachs at the junction of the longitudinal and transverse portions Borchers[3] showed that the frequencies of gastric contractions above and below the line of section were quite independent of each other in the longitudinal part four waves of contraction occurred in the same time that two or three occurred in the transverse portion below the section Borchers also showed that section nearer the pylorus was followed by tonic contraction of the pyloric antrum Gastric emptying is not the only factor influencing peristaltic activity The physical state and the nature of the gastric contents are also important, fluid contents pass out rapidly, and food containing a high proportion of fat is retained longest[4]

Lilja[5] has related the appearances during radiological examination with the structure and behaviour of the healthy and the ulcerated stomach The appearances in peptic ulceration are well recognised Chronic ulceration in the upper and middle thirds of the stomach is associated with shortening of the lesser curvature and increased indentation of the greater curvature in the longitudinal part of the stomach, an ulcer on the upper third of the posterior wall of the longitudinal part with a cascade type of stomach, a penetrating ulcer at the angulus with impaired emptying and dilatation and poor peristalsis in the transverse portion of the stomach, and ulceration in the roof of the transverse portion with concentric antral contraction Lilja suggests that in ulceration of the longitudinal part of the stomach spasmodic contraction of the inner coat of oblique muscle-fibres is later followed by fibrosis, and that in ulceration at the angulus there is peristaltic conduction blockage He suggests, too, that angulus ulceration may destroy a specialised motor centre situated there

The influence of gastritis on the appearances of the stomach outline is debatable Henning[6] stated that broad and thick folds in the stomach were often seen radiologically in a stomach that was histologically normal, and that even with total atrophy of the mucosal layer the rugæ might appear broad and thick Increased folding and irregularity in the stomach outline may result from increased gastric tone Magnus[7] stated that in chronic gastritis a considerable decrease in the number of mucosal glands might be accompanied by a corresponding increase in the areolar tissue in the mucosa, and that accordingly the mucosa itself might not become as thin as it would otherwise be Magnus regarded the mucosal change in pernicious anæmia as purely atrophic, without any increase in the interstitial tissue This true atrophy is limited to the longitudinal part of the stomach and terminates abruptly, the mucosa in the transverse portion of the stomach is *either normal or the seat of non-specific* gastritis The atrophic changes in the longitudinal part of the stomach in pernicious anæmia involve all coats of the stomach, and the naked-eye appearance is striking Pitman and Laws[8] suspect pernicious anæmia when they observe radiologically a smooth fundus devoid of normal folding, a smooth and rather uniformly tubular longitudinal gastric segment with poor peristaltic contraction, and fine " crushed tissue-paper " rugæ in the empty longitudinal part of the stomach with normal rugal pattern in the transverse part These findings are complementary to Magnus' account of the histological appearance In this instance the radiological diagnosis of gastritis seems to have passed beyond the stage of mere fancy

The work of Lilja and others shows that the connection between lesions of the mucosa and the substrate of muscular tissue of the stomach wall is closer and more extensive, even in non-neoplastic conditions, than many of us had thought likely

ALCOHOL AND DRIVING ABILITY

A NEW Medical Research Council memorandum[9] describes experiments designed to investigate the effects of small doses of alcohol on a skill resembling car driving[10] Inquiries were also made into individual differences in response to alcohol, particularly in relation to personality ratings, and various methods of estimating blood-alcohol were compared

10 See *Lancet*, 1959, ii, 51

The subjects of the experiments were 35 male and 5 female members of the staff of the Road Research Laboratory, 1 was aged 58, and the others were between 23 and 40 All were of good intelligence, and most were occasional or moderate drinkers All held driving licences, but they had had varied driving experience The skill tested was that of " driving " a fixed car-like apparatus (a Miles motor-driving trainer) along what appeared to the subject to be a winding tree-fringed road During a 30-minute practice run, blood samples were drawn to familiarise the subject with this procedure, and personality testing was performed the same day A week later each subject began a series of 5 regular weekly 2-hour " driving tests ", after taking one of five standard drinks four consisted of a 20% solution of ethyl alcohol with an alcohol content corresponding to 0 20, 0 35, 0 50, and 0 65 g per kg body-weight per subject, and the fifth was an alcohol-free " placebo " All were heavily flavoured with peppermint and ginger so that it was impossible to detect whether alcohol was present or in what amount During the test run an automatic record was made of " speeds ", tracking errors (i e , variations from a steady course), kerb bumpings, steering-wheel and accelerator movements, brake applications, and gear changes Save for kerb bumps, which were signalled by a loud buzzer, the driver was not informed of his performance during the tests Each test was interrupted every half-hour when samples of blood (by pinprick), urine, and occasionally breath were taken for alcohol estimations

The largest dose of alcohol was equivalent to about 3 pints of beer or 5 fluid ounces of whisky, for a man of average weight, and after each alcoholic drink the blood-alcohol rose sharply to a peak in 30–60 minutes Urinary alcohol rose more slowly and to a higher peak than in blood Tests on breath samples showed that, with the 'Drunkometer' and 'Breathalyser' calibrated to give the corresponding blood-alcohol values, there was good agreement with directly measured blood-alcohol figures similar tests with the 'Alcometer' were satisfactory at first but then became unreliable, possibly because moisture accumulated in the apparatus

The results showed a definite decline in skill with increasing blood-alcohol, a deterioration of about 12% in driving accuracy was associated with a blood-alcohol of about 80 mg per 100 ml Drivers influenced by alcohol tended to steer less consistently and to deviate more and more from the nearside kerb swerves away from the nearside kerb were less quickly corrected, but any tendency to steer into this kerb was more rapidly controlled These responses resemble those of fatigued persons, and they may represent increasing tolerance to error—an increase in the " indifference range "—which may explain the subjective impression of improved precision when in fact skill is diminishing After alcohol, extroverts drove on with maintained speed and many errors, introverts, apparently anxious to demonstrate their efficiency and trying to overcome the effects of alcohol, either slowed down appreciably without necessarily improving performance, or else speeded up, usually with little increase in errors

The time lapse after drinking did not materially affect performance, the effect of alcohol, once apparent, persisted during the 2 hours of the test, possibly because the blood-alcohol did not fall appreciably in that time Age, sex, drinking habits, and driving experience showed no relation to individual differences in response to alcohol In the group as a whole, performance was affected by the lowest dose of alcohol—corresponding to a blood-alcohol of only 20–30 mg per 100 ml —and it seems clear from this carefully designed and conducted experiment that blood-alcohol in the smallest quantities detectable by existing instruments may cause measurable deterioration in skill

INVOLUTIONAL MELANCHOLIA

It has long been agreed that manic-depressive psychosis may start late in life, but whether there is another condition—" involutional melancholia "—is disputed The symptoms are said to differ from those of other depressive illnesses Anxiety, manifested by severe restlessness and agitation, is held to be conspicuous, retardation is usually not prominent, and there is often a rich development of delusions (frequently bizarre and hypochondriacal) centred on feelings of guilt [1] The onset is usually insidious and the previous personality somewhat obsessional Cases of this kind are certainly to be found, but often the picture does not accord closely with this description Perhaps, as Lewis [2] suggested, the rather different manifestations of depression in later life can be explained by the influence of age itself

The evidence for separating involutional from manic-depressive cases is largely genetic Thus Kallman [3] found that the risk of schizophrenia in first-degree relatives of involutional melancholics was 6%—significantly greater than in the general population—whereas the incidence in the relatives of manic-depressives was no greater than the average But Kallman's concept of schizophrenia is wider than that usually accepted here, and doubt has been cast on his findings Kay,[4] for example, in his Stockholm study found an incidence of 2 5–4 2%, but of his 10 probands with schizophrenic relatives the majority had atypical psychoses, and in 3 there had been doubts about classification Also, of the 11 schizophrenic relatives the diagnosis was regarded as doubtful in 4 He concluded that " the risk for schizophrenia among the relatives is not definitely increased " Stenstedt,[5] in a particularly careful study, detected no increase of schizophrenia among the relatives of 307 involutional melancholics Affective illness, however, appeared in about 6% of the first-degree relatives, compared with some 3% in the general population and 12% among similar relatives of patients with manic-depressive psychosis [6] In his cases, as in those of Kay, there were more with prominent exogenous factors than is usual in a group of younger depressed patients Exogenous factors were particularly prominent in the oldest age-groups, where the incidence of affective illness in relatives was also less Excluding cases with presumed exogenous factors, the incidence in relatives was 9 4%—not dissimilar to the figure in cases of manic-depressive psychosis It seems that the earlier the onset the more " endogenous " the illness and the greater the genetic predisposition

Perhaps " involutional melancholia " embraces a heterogeneous group of disorders, including manic-depression of late onset and simple depression with predominant exogenous factors There seems to be little justification for retaining it as a separate diagnostic entity

Points of View

HÆMATOLOGY IN BRITISH HOSPITALS

PRESENT CONDITIONS AND FUTURE POSSIBILITIES

J. V. DACIE
M.D. Lond., F.R.C.P.
PROFESSOR OF HÆMATOLOGY IN THE UNIVERSITY OF LONDON
AT THE POSTGRADUATE MEDICAL SCHOOL OF LONDON, W.12

HÆMATOLOGY is a relatively new specialty, and in this country hæmatologists were a rare species before the late war. Till then, in England at least, the investigation of blood diseases was carried out in most hospitals in a corner of the general pathological laboratory by the hospital clinical pathologist or his assistant. It seems hardly credible that in 1936 when I was resident pathologist in a London teaching hospital my duties, which were not confined to hæmatology, included carrying out unaided all the blood-counts made on inpatients and outpatients, including collecting the blood, and giving blood-transfusions, as well as collecting blood from the donors and cross-matching it. None of the small staff of technicians helped with the blood-counts.

In the past twenty years or so knowledge of the blood diseases has advanced in many directions and many new and complicated techniques have been introduced; even the vocabulary of hæmatology has been transformed. Vitamin B_{12}, folic acid, Christmas disease, hæmoglobin-S, the Rh blood-groups, Coombs' test, and 6-mercaptopurine were all unknown in the late 'thirties. Each of these familiar terms is now surrounded by a vast literature, and the megaloblastic anæmias, the hæmorrhagic disorders, the abnormal hæmoglobins, blood-group serology, and the chemotherapy of leukæmia have all become subspecialties of hæmatology, each large enough for lifelong study. These remarkable developments pose problems of organisation and administration which I feel have not received the attention they deserve. The particular problem with which I am concerned is how best a hæmatologist and the hæmatological department (if there is one) can be fitted into the organisation of hospital medicine.

PRESENT PATTERN

Today a hæmatologist is almost always a pathologist who has spent nearly all his professional life in a laboratory. He may spend all his time on the investigation of patients with blood diseases, or he may do this in addition to undertaking another branch of clinical pathology—e.g., bacteriology or chemical pathology. More and more, however, I believe the trend in the larger laboratories is towards appointing a pathologist primarily to do hæmatology and to help with other branches only in emergencies or when another member of the staff of the pathological department is on holiday. He probably also supervises the transfusion services of the hospital. In large institutions, and particularly in the teaching hospitals, the laboratory hæmatologist, as I shall call him, often has his own staff of medically qualified assistants.

This pattern is, I believe, almost universal in England—even in teaching hospitals where the medical unit also specialises in hæmatological work and has its own laboratory and staff and carries out hæmatological investigations on the unit's patients. Even then the hæmatological work of the rest of the hospital is usually done by a hæmatologist in the hospital's clinical-pathology laboratory. In Scotland, though there are professorial medical units whose chief concern is hæmatology, hæmatological investigations have in the past usually been carried out in clinical side-rooms by the staff of the physicians in charge of wards, with occasional consultation with or reference to a colleague. This traditional procedure can hardly be expected to keep abreast with the demands of present-day hæmatological techniques, and in some hospitals at least other arrangements are being made.

DAY-TO-DAY DUTIES

The scope of a laboratory hæmatologist's work varies with local circumstances, but, leaving aside the possibilities of teaching and research, his work falls into two main categories.

First, he has to organise and supervise for his hospital a routine or screening service from which the medical staff of all departments can obtain elementary but expertly interpreted hæmatological data on their patients—e.g., hæmoglobin, leucocyte-counts, prothrombin-times, reports on blood-films, blood-grouping and cross-matching tests, and tests for antibodies in antenatal patients. All this work, more often than not, gives normal results and is usually left to the technical staff. It is time-consuming, exacting, and wearisome, but necessary, and it should be supervised by a hæmatologist. Its centralisation in a single laboratory enables this to be done and makes possible the early diagnosis of blood diseases. Shortage of staff often makes it difficult for the hæmatologist to give as good a service as he would like to, and here clinicians can help tremendously by leaving the decision as to what should be done and what need not be done in a particular case to the hæmatologist's judgment.

The second, and more exciting, side of a laboratory hæmatologist's work is the detailed investigation of patients whose blood is abnormal. In this he can often be of real help to his clinical colleagues, for it is almost impossible to diagnose a blood disease exactly without the aid of laboratory tests and experience in interpreting the findings. The central position of his laboratory (this unfortunately is often not geographically true), with all the patients in the hospital potentially a source of hæmatological problems, gives the laboratory hæmatologist remarkable opportunities for the study of a wide range of blood diseases at all stages in their evolution. In this way he rapidly becomes experienced in the investigation of obscure conditions and in advising on the treatment of blood diseases generally; particularly is this true of the management of patients with megaloblastic anæmia, leukæmia, hæmophilia, and hæmolytic anæmia. Recognition of this has led to the hæmatologist sharing more and more in the patient's care, and to the physician in charge often passing over to him the virtual management of the patient's hæmatological treatment and follow-up. This arrangement is a happy one for the laboratory hæmatologist and the physician as well as for the patient.

Finally, the hospital clinical-pathology laboratory may provide a general-practitioner diagnostic service. If so, an important part of this work is hæmatological. I do not deny that this is necessary, but in my view a proper provision of space and staff should be allotted for this work.

RESEARCH

It is every doctor's clear duty to contribute to knowledge of the branch of medicine in which he is working, and facilities for this and encouragement should, ideally, always be available. This is of course easier in the teaching hospitals than elsewhere, and it is unrealistic to suppose that a hæmatologist working in the clinical-pathology laboratory of a busy non-teaching hospital is likely to have time for research In most instances he has barely time to do the basic essentials of his work As for reading, trying fancy techniques, or experimentation, these are impossible But for the fortunate few who have the time, or make the time, the relation between clinician and hæmatologist is important, for the type of research possible to a hæmatologist almost always involves multiple tests on patients, careful follow-up studies, or assessment of responses to treatment It seems right to me that the man who supervises the routine hæmatological work should have the opportunity of carrying out research in the same field, alone or in collaboration with his clinical colleagues I regard it as an unhappy state of affairs if the laboratory hæmatologist is prevented from carrying out research because he has not easy access to patients

It is unfair to the hæmatologist if research on blood diseases is carried out by the clinical staff (who use the hæmatologist's basic data) because they have the time and the necessary apparatus as well as complete access to the patients, while the hæmatologist (who may know more about the problem) is left with his insufficient staff to cope with the routine demands of the whole hospital Under these circumstances a post in the hospital clinical-pathology laboratory is hardly likely to attract first-class applicants

SUGGESTIONS FOR THE FUTURE

I have tried to sketch briefly some of the problems surrounding the hæmatologist and his laboratory How about the patient? He clearly needs to be looked after by a physician who can view him as a whole as well as having his blood disease accurately diagnosed The effects of a blood disease are seldom confined to the blood, almost every system in the body, from the brain to the heart, gastrointestinal tract, kidneys, and skin may be involved For this reason, I have never subscribed to the idea that the laboratory hæmatologist should aim at having beds of his own and complete charge of patients But how can the laboratory hæmatologist's knowledge and experience and his natural desire for some control over the investigations and treatment of patients be reconciled with the undoubted right of clinicians to have full charge of and responsibility for patients in their care? This is the crux of the problem, and I believe it exercises to a greater or lesser degree the mind of every laboratory hæmatologist

My solution (which some may consider a pipe-dream, wild and impracticable) is in essence that hæmatology should be recognised as a subject worthy of a department to itself, and that the department, while retaining its administrative links with the department of pathology or the clinical-pathology laboratory, should have a definite link with the medical side of the hospital The staff of my ideal department of hæmatology would be

1 *The laboratory hæmatologist (director of hæmatological laboratory)* He should be primarily a clinical pathologist, who has had a good basic training in general pathology, but who has spent most of his professional life working at hæmatology He should not be a clinician, though the more he knows of clinical medicine the better

2 According to the size of the hospital, whether it is a teaching hospital or not, and the character of the teaching, the director should have one or more colleagues of consultant grade One of these should be a *consultant physician holding a joint appointment* in the departments of medicine and hæmatology He should have beds over which he has full charge, and these beds should be reserved for hæmatological problems He might perhaps have a few general medical beds also *The hæmatological physician* (as I shall call him), with the laboratory hæmatologist and other members of the department of hæmatology, would act as consultants, if asked, for hæmatological patients throughout the rest of the hospital Such an appointment would provide openings for young physicians with a deep interest in hæmatology but who wish to remain physicians and to have contact with and responsibility for patients with blood diseases At present opportunities for such physicians are almost non-existent in this country Their training should have been as physicians, and they need not necessarily have had any previous experience of general pathology in order to get appointed, though they would find this an advantage They might well develop research interests in such subjects as chemotherapy applied to blood diseases

3 Again according to the size of the organisation, there should be one or more registrars, at least one of whom should be a trainee physician working partly in the laboratory and partly in the wards

4 It would be desirable to have one of the hospital radiotherapists specialise in the application of radiotherapy and radioactive isotopes to hæmatological diseases He might well have some status in the department of hæmatology

5 An adequate staff of technicians, secretaries, laboratory clerks, &c I believe that most laboratories are understaffed

The size of the hæmatology department will naturally vary greatly from hospital to hospital Nevertheless, the principle of a close link between hæmatology and medicine could, I think, be applied almost anywhere The duties of the department would broadly be (the order is not meant to have significance)

The provision of a routine, or screening, diagnostic hæmatological service for the whole hospital

The investigation and exact diagnosis of cases of blood diseases throughout the hospital, the supervision of treatment of inpatients with blood diseases in the department's beds, and the provision of an advisory service for the rest of the hospital

Organisation of follow-up clinics for blood diseases, including megaloblastic anæmia, hæmophilia, leukæmia, and polycythæmia clinics, as well as joint clinics, with the appropriate clinical staff, for blood abnormalities which are commonly associated with another disease—e g, anæmia and disease of the gastrointestinal tract

The provision of a blood-transfusion service for the hospital, excluding giving blood and bleeding donors

The conduct of research and teaching

" The good husband is now the *domesticated husband*—the man who, when he has finished his work at the factory or the office, spends his evenings and his weekends not with his workmates but at home with his family, enjoying common fireside relaxations with them, or else 'pottering' round the house maintaining or improving its comfort and appearance Once he sought to escape from the crowded shabbiness of his home to the warmth and conviviality of 'pubs' or the club rooms of voluntary associations, and inevitably in the process he developed social interests and wider loyalties But now the new man stays at home, and he is likely to find burdensome and repugnant any activities or interests that force him to leave the family circle and to forgo part of his domestic privacy and comfort If his outside contacts are weakened and reduced in favour of his home ties, this will affect *all his group relations* Reduced attendance at trades-union meetings, at Friendly Societies and other club activities, at political discussions, and at all forms of outdoor mass entertainment and activity will inevitably affect his attitudes towards the social institutions they serve Thanks to television and *radio* he is, as a spectator and listener, able to sit at home and participate in these activities to a much greater extent than ever before But the participation is that of a detached, isolated observer served by technicians who are able to multiply his eyes and his ears, *and by commentators* able to develop his professional critical abilities "—MARK ABRAMS, *Listener*, Nov 26, 1959, p 915

THE COST OF DRUG TREATMENT

Henry Miller
M D Durh., F R.C.P , D P M
Michael Smith
M B Durh
From the Neurological Department, The Royal Victoria Infirmary, Newcastle upon Tyne

Man's addiction to pills and potions is as old as history, but until recently reliable evidence has been lacking about such changes as may have occurred over the years in the relative proportion of our national resources which has been devoted to the provision of drugs

Official anxiety about such expenditure dates from the time when this first became a charge on public funds, and has become more vocal with the much-publicised rise in the national drug bill from £31 million to £62 million which took place between 1949 and 1958 For the first time this change in the method of payment for medicines has permitted an assessment of their national consumption in terms of money, and has activated the concern which is always evident in matters of public accountability the equanimity with which a comparable dissipation of national resources was regarded while the transactions remained in private hands is a familiar phenomenon

The discovery by politicians that a comprehensive health service—even though it is no longer literally " free and open to all "—is an even more expensive business than they had anticipated has provoked a crescendo of Ministerial inquiries and exhortations which conveys a general implication that either the rapacity of patients or the complaisant negligence of doctors, or both, must be held responsible for a considerable proportion of the rising costs The administrators' failure to evolve a less expensive system of supplying the drug to the patient, and the politician's responsibility for inflation, are less frequently inculpated in public discussion, although in fact allowance for the falling value of the pound during the decade in question reduces the " real " increase in the drug bill from 100% to 40%

Official homilies are couched in general terms, and often deal with figures so astronomical as to be meaningless to the average doctor The present paper is based on a clinical lecture to medical students, directing their attention to the average weekly cost of some widely used forms of medical treatment with drugs as they are dispensed in general practice This seemed a simple enough undertaking, but we soon discovered that the problem was both more complex and more intriguing than would appear at first sight Finding that our ignorance of the subject was shared by many of our colleagues we considered the facts worthy of wider circulation

Method of Costing Prescriptions

The total cost of a general practitioner's prescription is the sum of four separate items (1) the basic cost of the drug, (2) the " on-cost ", which is 25% of the basic cost, and represents the permitted margin of gross profit to the pharmacist, (3) a container allowance of about 1½*d* , and (4) a dispensing fee of at least 1*s* 2*d* for the pharmacist's professional services Under present conditions the patient contributes 1*s* to the cost of each prescription It will be seen that the " basic cost of the drug to the N.H S " may be a very different matter from the actual charge on the Exchequer

Indeed, the system has some curious results The " basic cost " of half a grain of phenobarbitone three times a day for a week is 1*d* The " on-cost " raises this to 1¼*d* and the container allowance to 2¾*d* A dispensing charge of 1*s* 2*d* recompenses the pharmacist for the professional skill involved in dispensing the prescription The total cost of the pennyworth of phenobarbitone is therefore raised by more than 1600% to 1*s* 4¾*d* The example of terramycin shows the working of the system in a different way The basic cost of one gramme of this drug daily for seven days is £1 19*s* 8*d* On this the pharmacist is allowed a profit of 9*s* 11*d* and a dispensing fee of 1*s* 2*d* , raising the total cost of a week's supply of the drug to £2 10*s* 10½*d*

Examples

The weekly cost of treatment with some familiar drugs in average doses as prescribed by the general practitioner is set out below to the nearest penny The figures relate to prices prevailing in July, 1959, and have been averaged to allow for occasional variable factors The " prescription charge " of 1*s* is excluded from consideration here, but it is universally applicable, and has the effect of reducing the cost to the Exchequer by 1*s* in every instance

CARDIOVASCULAR DISEASE

The treatment of *heart-disease* is generally inexpensive. The average weekly cost of digitalisation varies from 1*s* 5*d* (digitalis leaf *N F*) through 1*s* 6*d* (tincture) and 1*s* 9*d* (digoxin) to 2*s* 0*d* (digitoxin) The weekly injection of mersalyl costs 1*s* 8*d* (basic cost of the drug is 3½*d*) but four days of ' Saluric ' costs 5*s* 8*d* and a week's supply of hydrochlorothiazide 10*s* 6*d*

The long-term medical management of *hypertension* is usually a more expensive business, the average weekly cost of ' Serpasil ' being about 2*s* 9*d* , ' Ansolysen ' 6*s* 3*d* , ' Apresoline ' 6*s* 7*d* , ' Tenormal ' 7*s* 10*d* , and ' Inversine ' 8*s* 3*d* If pilocarpine is administered simultaneously to control side-effects the cost is raised by another 5*s* 6*d* weekly

The treatment of *angina* costs 1*s* 5*d* per week with nitroglycerin, 1*s* 11*d* with ' Peritrate ', 2*s* 5*d* with ' Mycardol ', and 6*s* 2*d* with ' Marsilid '

With regard to *anticoagulant* treatment, heparin is notoriously expensive (£2 17*s* 6*d* for 48 hours), dicoumarol at 3*s* 2*d* and ' Dindevan ' at 3*s* 0*d* weekly much less so

NEUROLOGICAL DISORDERS

The cost of treating *epilepsy* varies from 1*s* 5*d* weekly (phenobarbitone) through 2*s* 6*d* (' Epanutin '), 4*s* 3*d* (' Mysoline '), and 5*s* 6*d* (' Tridione ') to £1 6*s* 6*d* (' Nydrane ')

For the prophylaxis of *migraine*, Gowers' mixture costs 2*s* 5*d* weekly, ' Stemetil ' 6*s* 6*d* However, the treatment of an individual attack with three tablets of ' Cafergot ' may cost from 1*s* 6*d* to 2*s* 6*d* , and with ' Migril ' from 2*s* 1*d* to 3*s* 11*d* , depending on the number of tablets prescribed at a time

Myasthenia gravis is a fairly expensive illness In low average dosage of two fifteen-milligramme tablets three times daily ' Prostigmin ' costs 6*s* 6*d* weekly, comparable dosage with ' Mestinon ' 15*s* 3*d* For parkinsonism ' Artane ' (3*s* 1*d*) now costs no more than tincture of stramonium or hyoscine hydrobromide ' Cogentin ' (6*s* 2*d*) is twice as dear, but ' Kemadrin ' (2*s* 8*d*) represents one instance where the prescription of a proprietary drug represents an economy

Wilson's disease costs 3*s* 4*d* weekly treated with calcium versenate, 4*s* 11*d* with dimercaprol (BAL), and about £15 10*s* 0*d* with penicillamine

INFECTIONS

Sulphonamides are cheap, a week's supply of sulphamezathine costing only 3*s* 2*d* The weekly cost of a daily injection of one mega-unit of penicillin is 10*s* , but oral penicillin V in tablet form in dosage which most would consider no more than adequate for the treatment of a severe infection (one gramme daily) might cost £1 7*s* 6*d* weekly, or £2 19*s* 7*d* in suspension In the latter form, indeed, oral penicillin is probably the most expensive antibiotic in general use, the average weekly cost of the others varying from £1 13*s* 4*d* ('Chloromycetin'), to £2 5*s* 0*d* (erythromycin), £2 7*s* 1*d* (aureomycin and 'Achromycin'), £2 10*s* 10*d* (terramycin), and £2 18*s* 2*d* (neomycin)

Streptomycin costs 14*s* 5*d* weekly and isoniazid only 1*s* 10*d*, but *p*-aminosalicylic acid (P A S) £1 2*s* 11*d*

ENDOCRINE PREPARATIONS

The cost of treatment of *diabetes mellitus* is almost independent of the type of insulin employed Twenty units of soluble insulin twice daily costs 5*s* 1*d* weekly, protamine zinc insulin or globin insulin in comparable dosage 5*s* 3*d* A syringe and one packet of needles costs 8*s* 1*d* Tolbutamide (5*s* 10*d*) is comparable in cost with insulin

In the treatment of *hypothyroidism*, L-thyroxine (1*s* 10*d*) is only slightly dearer than thyroid extract (1*s* 6*d*) In Graves' disease a week of methylthiouracil costs 1*s* 5*d*, a week of 'Neo-mercazole' 4*s* 0*d* In the treatment of *Addison's disease* ten grammes of sodium chloride daily costs 2*s* 7*d* weekly, fluorohydrocortisone 6*s* 6*d*

The comparative costs of various therapeutic routines in *rheumatoid arthritis* are of some interest Aspirin costs 1*s* 10*d* weekly, calcium aspirin 2*s* 7*d*, 'Paynocil' 6*s* 0*d*, 'Butazolidin' 8*s* 7*d*, prednisone 15*s* 5*d*, and cortisone £1 0*s* 10*d*

EMOTIONAL SYMPTOMS

Modern preparations for *sleeplessness* are not expensive Nightly 'Soneryl' costs 1*s* 11*d* weekly, 'Seconal' 2*s* 1*d*, 'Tuinal' 2*s* 8*d*, and 'Carbrital' 3*s* 2*d*

'Amytal' (2*s* 0*d*) remains the cheapest ataractic, 'Largactil' costing 3*s* 10*d*, 'Oblivon' 4*s* 0*d*, and 'Equanil' 4*s* 4*d*

'Dexedrine' in tablets costs 1*s* 5*d*, in 'Spansule' form 2*s* 6*d* The new antidepressive preparation 'Tofranil' costs 17*s* 6*d* weekly for average maintenance dosage

Discussion

These figures demonstrate the low basic cost of many of the drugs most widely used It is a remarkable tribute to the efficiency of the pharmaceutical industry that a week's supply of phenobarbitone or digitalis in reliably standardised dosage can be furnished by the industry for a "basic cost" of 1*d*, with dextroamphetamine for 1½*d*, and with thyroid extract for 2*d* In such instances a distributive cost which may exceed 1500% is startling, while the "on-cost" *in the case of the more expensive* preparation (e g, 11*s* 4½*d* on seven grammes of neomycin) also makes an appreciable contribution to the final cost of the prescription In general the cost of distribution adds 50% to the basic cost of the drugs considered above —a figure which suggests that distributive costs may account for one-third of the total national drug bill

The dispensing fee is intended as remuneration for the pharmacist's professional services in making up the prescription In the calculations noted above the flat-rate dispensing fee of 1*s* 2*d* has been added to the basic cost of the drug, but in fact this is the minimum The dispensing fee on 42 tablets of phenobarbitone is 1*s* 2*d*, but on a prescription for 350 tablets it is 4*s* 0*d* The compounding of medicines in the pharmacy is steadily declining, and at the present time probably rather more than three-quarters of all National Health Service prescriptions are for tablets the dispensing of which does not call for any high degree of professional skill

Expensive Drugs

Expensive drugs are of three kinds first, those which are genuinely expensive to manufacture (e g, penicillamine), secondly, new drugs in which the costs of development must be recouped by an initially high price (e g, nydrane), and, thirdly, special preparations of banal remedies (e g, phenobarbitone in spansule form)

Penicillamine is produced by a complex and expensive chemical process, and it has no use whatever except in the treatment of Wilson's disease The high cost of the drug covers no more than the expense of manufacture Its use represents a real advance in the treatment of this distressing disease It goes far to correct the biochemical anomaly which is at the root of the condition, and may produce considerable symptomatic improvement It is not a cure and it rarely restores social efficiency On the other hand its employment may allow home rather than institutional care It is difficult to see any justification for denying its continued administration to any patient with this disease who obtains unequivocal benefit from it, but at an average annual cost of £750 its prescription cannot but cause the physician some concern

One special reason for this is that although the day-to-day care of the patient may have passed into the hands of her general practitioner the drug is always distributed from a hospital pharmacy, and the maintenance of two sibs with Wilson's disease may saddle the hospital with an annual expenditure of £1500 or more The physician knows that no special financial allotment is made in such cases, and that the money must come from an annual Ministerial allowance for running expenses which is regularly thousands of pounds below what the hospital administration has carefully estimated as necessary to provide an efficient service In fact he knows that the provision of such treatment may reduce the amount of cash available to the hospital for the purchase of such requisites as surgical instruments

The *instance of penicillamine* emphasises another anomaly of wider implications It is cheaper to supply drugs from a hospital dispensary than by means of a general practitioner's prescription dispensed by a private pharmacist The hospital has the advantage of bulk purchase, there is no "on-cost", and the proportion of the hospital pharmacist's salary which can be related to the service involved in a single prescription is very much less than even the minimum dispensing fee of 1*s* 2*d*[1] However, the system of hospital budgeting is such that some hospital administrations have found it necessary to advise their medical staffs to cut down the treatment of outpatients with drugs from the hospital dispensary in favour of the patient's earlier reference back to his general practitioner, even though there are many instances where hospital supervision is a convenient as well as an efficient and economic temporary arrangement Paradoxically, the hospital, in an attempt to balance its own budget, finds itself obliged to advise a course of action which involves an increased charge on public funds

Difficulties also arise in relation to the second group of expensive drugs At a time of unparalleled advance in pharmacology the doctor is subjected to a daily barrage of advertisements for new preparations, many of which are expensive A few of these find an established place in current therapeutics For example, artane, introduced as a rather expensive proprietary preparation ten years ago, is now probably the most widely used drug in the treatment of Parkinson's disease and has become slightly cheaper (as well as more convenient and more chemically stable) than the traditional hyoscine and stramonium mixtures it has largely displaced However, had artane not proved its worth during the course of sporadic and haphazard employment over the course of a few years by thousands of doctors—at a time when it was still an expensive and untried drug—the benefit of this advance might never have been extended to the majority of patients with parkinsonism. This process of assessment could have been expedited by the early commission and publication of controlled therapeutic trials. Modest expenditure on this branch of clinical research would be an economic investment: for example, a small-scale investigation in this department[2] defined the limited role of one of the more expensive modern anticonvulsants in the management of epilepsy, and has probably rendered its widespread routine employment a little less likely.

---

[1] Martin, J P Social Aspects of Prescribing London, 1957

The third type of expensive drug—the special preparation or combination of banal remedies—is an Aunt Sally for the critic, and indeed the marketing of expensive hæmatinic *olla podridas* and unholy combinations of vitamins and sedatives by otherwise reputable firms greatly strengthens the hands of those who would like to restrict the doctor's freedom to prescribe. But in fact many of the preparations in this group are extremely valuable. The long-acting effect of a spansule of phenobarbitone may make all the difference in the control of the difficult epileptic whose fits occur in the early morning. And although hard words have been used by purists about multi-vitamin preparations it would be negligent as well as doctrinaire to withhold them in the complex and ill understood metabolic disturbances manifested by a malnourished alcoholic or a patient with an obscure malabsorption syndrome.

It is clear also that the cost of drugs cannot be considered in isolation from other aspects of medical care. The prescription of oral penicillin in massive dosage in place of the less expensive injection not only may be imperative in the needle-shy child but also may be economic in a distant farm-labourer with a respiratory infection, to whom each visit may involve opening half a dozen moorland gates. Six months of tofranil for a depressed patient may push up the national drug bill by £30. The fact that such expenditure has saved £300 by averting admission to hospital will be sought in vain among Ministerial statistics.

That some doctors indulge in what some other doctors regard as over-prescribing cannot be doubted. But attention is less frequently drawn to *under-prescribing* by doctors who for one reason or another—sometimes undoubtedly for fear of administrative criticism from above—fail to give their patients the benefit of expensive remedies scientifically validated as outstandingly effective. In the same way it is often inferred that the higher average cost per prescription encountered in more prosperous localities[1] is due to extravagant or "excessive" prescribing. Since this high average prescription cost also correlates with a lower than average morbidity, a decreased frequency of prescription per patient, and a smaller than average number of patients per general practitioner, it could be quoted with at least equal justification as demonstrating a high and effective standard of medical practice worthy of more widespread emulation. Attractive though the economical doctor may be to the administrator, evidence is lacking of any correlation of low-cost prescribing with professional efficiency, and it seems improbable that even a Treasury officer would regard such parsimony as a quality to be sought in the choice of his own medical attendant.

In fact, although the view that extravagant prescribing makes a material contribution to the national drug bill is evident in much that is said and written on the subject, any factual basis for such a suspicion is lacking. It is certainly implicit in two measures which have been repeatedly recommended in the hope of holding back rising expenditure—limitation of the quantity of drugs to be permitted on a single prescription, and the employment of cheaper remedies where this is possible. The first of these is unexceptionable so long as it is not applied in the case of the very large number of chronic patients, in every branch of medicine, who require permanent or long-term maintenance dosage with relatively infrequent professional attendance. Any limitation of the quantity of drugs available on a single prescription in these cases would materially *increase* the cost of treatment, besides wasting the time of the doctor and the dispenser. Indeed the contribution of any restriction of quantity could hardly be more than to discourage such waste as now occurs in the treatment of acute illnesses.

The frequently reiterated Ministerial exhortation to employ cheaper remedies wherever possible presents greater difficulties, and is indeed not easy to reconcile with a deeply ingrained professional attitude of doing the best possible for each individual patient. It is easy for a Civil Servant to write such a recommendation into a memorandum but a very different matter for the doctor to offer something "second best" to a sick patient. We are indebted to a distinguished academic colleague for a practical suggestion towards the resolution of this ethical difficulty—that a small hospital be established for the carefully controlled assessment of cheaper treatments. He suggested that such a hospital might perhaps be situated conveniently for Whitehall, so that it could at once serve the physical needs and satisfy the public spirit of senior Civil Servants and politicians.

Conclusions

The desire to find a scapegoat to be held responsible for any unpalatable occurrence is universal, and is evident in the tendency to saddle the doctor, the patient, or the pharmaceutical industry with responsibility for the rising national drug bill. It is our contention that this is in fact the inevitable price of the present scientific revolution in medicine. The benefits of this revolution are evident in almost every field of vital statistics, as well as in an inscrutable but enormous reduction in the total amount of suffering in the community. But they cannot be obtained unless they are paid for. The tempo of medical research shows no signs of slackening, but rather the reverse. It is worth noting that the pharmaceutical industry alone spends a sum of money on research each year which is appreciably greater than the total annual budget of the Medical Research Council; even in the matter of basic pharmacological research its output dwarfs anything that can be achieved with the inadequate facilities afforded in the exiguous pharmacological departments of the universities. Unless the pace of research slackens—in which case neither the medical profession nor the industry will deserve well of the public—the drug bill, like the cost of the Health Service as a whole, is bound to rise. Whether such an increase need outstrip increasing national productivity is not a problem for the doctor. In the meanwhile an annual increase of 3·4%, at a time of previously unparalleled progress in therapeutics, seems to us to have caused quite disproportionate surprise and alarm.

PRIORITIES IN SOCIAL WELFARE

ADDRESSING the National Council of Social Service on Dec 8, Prof FRANÇOIS LAFITTE suggested that since 1948 we had been trying to extract a quart of welfare and defence from a pint of resources As a result our actual social programme differed from the proposals of the famous blueprints for post-war social reconstruction

The blueprints had presupposed a massive investment in re-equipping the social services with buildings and institutions good enough and diverse enough to serve the widened aims of social policy—health centres, small welfare hostels, secondary modern schools, hospitals, dental clinics In fact 1954 was the first post-war year in which the physical volume of capital resources put into the social services (including education) even reached the inadequate level of 1938 Until we had got over the hump of rearmament and the housing boom, in real terms the claims of the health service were " frozen " and education was confined to its " essential fabric " However, by 1958 the health service was allowed to take 10% more real resources than in 1951 (all the increase occurring since 1954), but top priority was given to education (which received an increase of 36%)

Turning to the future, Professor Lafitte foresaw that the margin of public funds for welfare in the nation's budget would rise from initially £70 million a year to at least £400 million a year by 1964 This could either be returned to consumers, through tax reliefs, for individual enjoyment, or used to improve the social services for communal enjoyment A central issue of public policy was how to balance the claims of individual and communal enjoyment A large part of the " welfare margin " was already earmarked by the Government for improving education Eventually education was likely to need up to £200 million a year extra Education remained the Government's no 1 priority " It is also mine," Professor Lafitte added, but he thought that after 1965 we could hope for a refurbishing of the health service's assets, to be followed in the early '70s by a housing boom, as the post-war " bulge " of children and their nearly as numerous successors took to marrying and home-making

Since the war precedence had been given to the social services which help the ordinary family—maternity and baby welfare, family allowances, schooling, libraries, and medical and dental care Without neglecting these common services ought we not, he asked, to be doing more for the minorities with uncommon needs? If society did not adequately provide for those who needed support to offset handicaps, could it really be proud of how well it cared for the social needs of the normal majority? We should face the fact that economic advance was steadily bringing the mass of wage-earners into the lower middle-class income ranges It would be well for society if policy did more to quicken the spread of some of the lower middle-class virtues, such as budgeting over longer periods than a week or a month, and setting money aside for emergencies and old age Most ordinary earners were being carried so far above a subsistence standard of living that it was becoming steadily less reasonable to want a social policy which assumed that no great number of fully employed citizens could house themselves decently unless the State built the dwellings and subsidised the rent, or that hardship was caused if people had to pay any appreciable part of the cost of welfare milk, school meals, spectacles, dentures, and other simple requirements

In view of the growing prosperity of the ordinary citizen, Professor Lafitte would himself select, after education, the following social priorities

Services for the mentally ill or handicapped should be humanised and transformed in the direction of community care and aftercare Policy was already committed to this reorientation, but its implications had scarcely yet been studied Its attraction was that it would avoid institutionalisation, its danger was that it might mean a transfer of defenceless souls from skilled to less skilled care—or to no care at all If properly carried out, it would not be cheaper than the old method it would be more humane and sensible

Diversification and re-equipment of penal institutions were urgent, because they were nearly all presupposed by the Criminal Justice Act, which it was becoming fashionable to decry before it had been given half a chance to work effectively

Family welfare services should be remodelled and perhaps fused to form a general all-purposes service

Services for handicapped minorities were still inadequate and often less effective than they could be, because of their multiplicity

Extra age benefit for the over-seventies would recognise advanced old age as a special handicap Most old people of today had lived through two world wars, two post-war inflations, and an era of mass unemployment Their chances of saving must have been minute, compared with those of the present working population

Social work and training should be expanded, for the " underdog " services were also undermanned services

Teenagers and the Bulge presented society with a challenge which we had partly failed to meet The main improvements in education would come after they had left school We kept adolescents at school longer than we used to, yet they matured earlier, and we had not really learnt how to handle, and what to teach, teenagers who were neither bookish nor intellectual, and who were no longer children For the first time in history working lads and girls had the means to assert their independence by dressing, spending, and behaving in distinctive ways If some of them went off the rails, were they not less to blame than the inflated economy, which gave them the means to snap their fingers at Dad, and the earlier neglect of their education?

MEDICAL JOURNALS FOR DOCTORS IN DEVELOPING COUNTRIES

THE British Supporting Group for the World Medical Association invites doctors in the United Kingdom to participate in a project for the regular supply of used British medical journals for doctors in " underdeveloped " countries—more especially in the Commonwealth—who, for various reasons, have at present little or no access to British medical literature A pilot experiment for doctors in India is to be started early in the New Year The scheme is to be essentially personal, an individual donor of used journals being placed in direct postal contact with an individual recipient The honorary secretary of the British Supporting Group will provide a stamped and addressed envelope or wrapper to the donor, who, once a month, will post his journals to the recipient allotted to him The journals which it is proposed to invite donors to send are the *British Medical Journal*, the *Practitioner*, and *The Lancet*

The scheme will, it is hoped, help to disseminate knowledge of British medicine and its methods among doctors in less developed territories The journals will be of value not only to individual readers or groups of readers, but also in forming a nucleus for a local reference library

Doctors who may be willing to take part are invited to get further information from the honorary secretary of the British Supporting Group for the World Medical Association, B M A House, Tavistock Square, London, W C 1

BIRTH CONTROL IN AMERICAN POLITICS

FROM A CORRESPONDENT IN THE UNITED STATES

CONTRACEPTION has become a major political issue here Last July the Draper Committee, who had been appointed by President Eisenhower to consider foreign military and economic aid, said in their report that the United States should give help, to nations that asked for it, " in the formulation of practical programs to meet the serious challenge " posed by populations growing beyond their means of support, and, answering a question, General Draper said that birth control was in the committee's purview This recommendation, which has not been acted on, attracted little attention until, in November, the Roman Catholic bishops issued a statement opposing " any public assistance, at home or abroad, to promote artificial birth control "

This statement has been criticised by other religious groups The head of the National Council of Churches (a Protestant organisation which, like the Roman Catholic Church in America, claims 39 million adherents) said that the decision of a President should be for his individual conscience and not be determined by the Roman Catholic Church—though he thought that private agencies would be a more suitable source of birth-control information than the Federal Government The New York Board of Rabbis said that birth-control aid should be given to countries that requested it But President Eisenhower (a Presbyterian) has said emphatically that birth control is not a proper Governmental responsibility He expressed respect for the Catholic Church, for which, he said, " this thing has religious meaning ", and though he added " this has nothing to do with Governmental contacts with other Governments ", it is widely held that his disclaimer is partly at least in deference to Roman Catholic views—especially since he made no adverse comment when the Draper Committee's report was first published, and it is said that it was on his insistence that the committee considered birth-control assistance [1]

The Protestant Council of the City of New York (which recently led the successful fight to make birth-control instruction legal in the city's hospitals) has complained that the contrary views of members of Protestant communions should also be taken into account, and a Presbyterian writer said that if the President's deference to the beliefs of certain sects was carried to its logical conclusion he would not let the Government contribute to armaments, because the Quakers are pacifist

The question has assumed political importance, not because of a split along party lines—many prominent Democrats have endorsed the President's attitude—but because at least two of the aspiring candidates for the Presidency next year are Roman Catholics, and the attitude of each to this issue may be taken as an indication of how his religious beliefs might affect his actions in general if he were elected President

There is some irony in the debate about American aid to foreign countries to promote birth control when many American States have laws restricting birth control, for instance, a Connecticut State law prohibits the use of contraceptive devices and forbids doctors to advise their use, even to save the lives of patients This law is being challenged before the Connecticut Supreme Court of Errors, and on Dec 22 the court unanimously upheld the " constitutionality " of two 1879 statutes which forbid the presenting of or use of birth-control drugs or devices [2] The plaintiffs, Dr C Lee Buxton, chairman of the obstetrics department at Yale University, and five unidentified patients of his, have announced that they plan an appeal to the Supreme Court

Personal Papers

AFTER NEARLY THIRTY YEARS

Plato says in *The Republic* that " the most skilful physicians are those who, from their youth upwards, have combined with the knowledge of their art the greatest experience of disease, they had better not be robust in health and should themselves have suffered from all kinds of illnesses " This method of instruction is not included in the medical curriculum and is fortunately imposed on only a few doctors Being one of this group and having had a full dose of Plato's prescription in my mature years, I propose to submit his theory to the test of my own experience

The illness was severe but never clouded my brain On the evening of Feb 17, 1930, after a few hours' premonitory symptoms, I became paralysed from the waist downwards, from transverse myelitis, while I was well on the way to recovery from a brief severe septicæmia The paralysis, which I unexpectedly survived, left a considerable legacy of disability, principally affecting locomotion, bladder, and bowel—a spastic paraparesis Certain aspects of this illness have already been recorded [3-5]

THE PATIENT'S FIRST QUESTION

The illness was considered hopeless, absolutely so I myself was well aware of its gravity Nevertheless, the next day I asked my physician " What do you think are the chances of my recovery ? " He replied without hesitation " I really do not know If I were pressed for an answer, I should say fifty-fifty " I was in no mood to dispute this kindly verdict, so I thanked him and said it was very encouraging, and we left it at that

On the twelfth day the distinguished brain surgeon, the late Sir Percy Sargent, kindly came to see me Before he left he came to my bedside and said, very, very kindly " I have now got a complete grasp of your case It is very rare I have seen only two similar cases I cannot tell what is going to happen to you, but I can say this, that I do not see any absolute reason why you should not, ultimately, almost completely recover, except for a slight weakness of the peroneal muscles of your right leg " This verdict, to one still completely paralysed, was a wonderful exhibition of clinical skill In my completely darkened sky, Sir Percy placed the bright star of hope That star never set He had, however, no expectation that I would survive No-one could have been more astonished than he, when we met about a year later at the meeting of the Association of Surgeons in Belfast, he himself told me so

These answers throw a little light on the vexed question of what the doctor should tell a patient suffering from hopeless illness He should not tell him anything disagreeable unless the patient really wants to know He should not tell a lie He should recognise the cases in which the truth is a relief from doubt, uncertainty, and fear He should never forget that he may be wrong He should speak very kindly and always if possible leave a ray of hope The second answer was worth the world to me

THE EMOTIONAL REACTIONS

It is the emotions that rule the lives of men In sudden severe illness the emotions are deeply stirred They should not be lightly interfered with The emotional complex of different people differs as much as their faces do, built-up by the daily habits of years A crisis, such as an illness, should not be used to upset them

Very curiously I had no emotional reaction to the actual onset of paralysis The tragedy had happened, and I simply accepted the fact There was no pretence about this, and I was—and I felt—as cheerful as before

The true meaning of this equanimity became apparent on the evening of the ninth day I was alone The fire had died down It was a dull dismal evening in late February Suddenly there swept across my mind a full realisation of what had happened to me, that I, laid in bed, could do nothing but raise my arms and move my head from side to side on the pillow, that I might continue to be utterly helpless as long as I lived, till death should release me All at once I could have shrieked and shrieked in a frenzy of despair What I did was to say to myself that this was not a nice thing to think about, and that I must think of something nice In a few moments the spectre fled, and I was calm again A horrid thought like this must be routed at its first onset

It recurred—only for a moment—the next evening And never again

On the eleventh day, a peculiar choice faced me—the free choice of life or death I said to my surgeon, on his morning visit, that I was on a slippery slope and if no change occurred would die in precisely four days He agreed that this would happen unless I resumed taking nourishment, and suggested Bengers food I was very emaciated Fourteen days earlier, I had been put on a waterbed to prevent bed sores because I was so thin For 11 days I had (by my own desire) lived on nothing but water and oranges (6–8 a day) I was mere skin and bone It was a dreadful choice Without telling her why, I put the question to my wife, the other person deeply interested, whether it was worth my continuing to live, even if paralysed She replied emphatically " Yes " So I asked for Bengers food After all, the other choice would have meant a cowardly exit from life

These emotional reactions are of great interest The delayed emotional upset, in its lateness, its suddenness, and its intensity is not unique, nor characteristic of a doctor The absence of an hysterical outburst is due to the medical training It is explained by Dr John Brown in *Rab and His Friends* The medical students at Edinburgh Infirmary were on their way to the theatre to watch an operation for advanced cancer of the breast This was about 1815, before the days of anæsthesia, and it must have been a dreadful spectacle " Up ran the youths, eager to secure good places, in they crowded full of interest and talk 'What's the case?' 'Which side is it?' Don't think them heartless they are *neither* better *nor* worse than you or I in them pity—as an *emotion*, ending in itself or at best in tears and a long drawn breath, lessens, while pity as a *motive* is quickened and gains power and purpose " This diversion or redirection of the emotions from their ordinary passive manifestations into an active channel is an essential part of the training of a doctor The ordinary manifestations of an emotion cause mental confusion and paralysis of action Its diversion into channels of activity induces presence of mind and stimulates helpful action This trained instinct prevented the hysterical attack

On the twelfth day, I had a further diversion of the emotions From the moment that Sir Percy Sargent implanted in me the hope of recovery, all my emotions and all my spiritual, mental, and physical powers were directed to one purpose—recovery It was my single aim, my distant goal

LEARNING TO WALK AGAIN

I learnt to walk as a child does, instinctively, by trial and error, by repeated effort The beginning was slow and required patience Not till six days after Sir Percy's visit did the first flicker of movement appear in my great toes I have a vivid memory of my happiness, the next day, when I could move both great toes. Then in slow succession came movement of all the toes, the ankles, the knees, and in the end the hip-joints My excellent Swedish masseur came for an hour a day, seven days a week, and on the day when I first got out of bed, precisely three months from the onset of paralysis, I was able to walk to and fro in front of the fireplace holding on to the mantelpiece surely a triumph for massage

Three weeks later I left the home for the seaside

" Like a child sent with a fluttering light
To feel his way along a gusty night " *

just able with stick in my right hand and my nurse on my left to walk slowly and uncertainly a little way Henceforth, the master word was perseverance, day in, day out, several times a day It would be idle to describe the detail, since Nature adapts with great precision the technique suited to each case, but there is one point I should like to dwell upon

I learnt very soon that I was doomed to fall frequently, and this has gone on all through the years It was not a defect of balance, for I could stand on either leg, but if my balance was upset my legs were so slow in moving that they could not always save me I found out in time all the causes of upset, but it was not always possible to avoid them Later on, I set myself to learn the art of falling safely (and if possible, gracefully) by diligent practice in a big room This was invaluable I also learnt and practised the special technique for rising unaided Let me give an example of the value of such practice

> I was coming out of the front door of a Scottish hotel (many years later) On the landing was a wire mat, which curled up as I stepped on it, and caught my foot, precipitating me head foremost down five steps on to the hard ground I at once took three measures for protection I used my stick on the steps, and broke my fall a little I tilted my body to the left side, and dropping the stick extended my arms I fell rather heavily on my left side, with no other injury than a bruise over my left great trochanter Presently I got up, and went into the hotel to give a friendly warning to the proprietor I then came out to resume my walk and found the mat already removed !

Constant practice, plus a very rapid reaction-time, enabled me to convert what might have been a nasty accident into a negligible mishap

I had, perforce, to bestow some thought on the analysis of my defective walking The general weakness of my legs very quickly improved, but I was never able to regain good power in flexing my hips and so had a shuffling gait, especially in my right leg which had a slight drop foot as Sir Percy had prophesied But my main defect was spasm of the muscles of the lower part of my back and the posterior muscles of the back of my leg, which slowed all the movements I never could clearly understand why the voluntary impulse from my brain should be not just weakened, but distorted or diverted so that my legs refused to do what I told them

---

* Bird Parliament, by Edward Fitzgerald

SLEEP

As soon as movement returned to my legs, I began to be troubled with nocturnal jerks, keeping me from getting to sleep and awaking me from deep sleep The simple and obvious remedy was sedative drugs My night nurse and I discovered a much better way

We found that the chief cause was too hot feet It cannot have been easy to find this out, as I had lost the sensation of heat and cold as far up as the ankle By cooling the feet and sometimes the legs I got to sleep, only to be wakened in ½–1½ hours by kicking legs The nurse would then cool the feet or legs and turn me over and I would go to sleep at once. This would be repeated at least six times each night, and yet I would get a good allowance of refreshing sleep

Sedatives or tranquillisers should not be used as symptomatic treatment until an intelligent effort has been made to discover and to remove the exciting cause Such drugs are not good for morale. The jerks have continued for thirty years, and have never required treatment with drugs

THE RETURN TO WORK

It was my full intention to return to my work as surgeon before the end of the year, but, as the hospital committee did not understand that this was possible, I was asked to go for review to London, as suggested by Sir Percy Sargent. The late Dr George Riddoch, whose work on injuries of the spinal cord during the first world war made him the acknowledged expert on this subject, gave his verdict in the beginning of December "You must return to work on Jan 1 This is not a piece of advice, it is an order You will, so far as your disability is concerned, soon be equal to your full work, and will be able to complete your full term as surgeon to the Royal Infirmary" This clear definite verdict, remarkable for its accuracy and its clinical acumen, was most valuable to me and enabled me to meet with full confidence all the difficulties that face the disabled man on his return to active life. For my part, although I had had considerable acquaintance during more than twenty-five years with the Workmen's Compensation Act of that day, it was not until I faced the problems of my own return to work that I fully realised the many hardships and often the unhappiness and anxiety that the disabled workman had to endure

MY DOCTORS AND NURSES

Since the above verdict, I never had a doctor (save for two minor incidents) during the next twenty-five years The explanation was simple In 1930, the treatment of paralysis, especially the spinal type, was neglected. It would have been difficult at that time to find a doctor who would have believed in my recovery or could have helped me. This had one great compensating advantage. It left me free to live my own life, not under doctor's orders, to carry out my full duties as surgeon and as citizen, to drive my car, to golf, to walk the moors, to climb—in short to live the full joyous happy life, with the spice of adventure in addition.

My nurses were wonderful they had worked with me, now they cared for me In particular they saved me from bedsores, no small feat They went about their work with the ease and grace which attend competence and experience Associated with them was one, not herself a nurse, who devoted to me an unwearying care, a courage and initiative, and a sound practical common sense, without which my recovery would have been quite impossible—my wife. My sickroom was a happy place A good nurse makes a good patient

THE URÆMIC EPISODE

About the age of 73 my health began to fail The symptoms of uræmia were atypical, and the urinary symptoms masked because of the automatic bladder After about three years I became disinclined to walk, ceased to perspire, was thirsty ate poorly, and lost weight I was advised to have my blood-urea taken It was 64 and was passed as high normal About two months later, after a short tour to Scotland, it was 138 I disbelieved this, because I had never had any headache and could still drive my car 200 miles in a day A fortnight later it was 158, and I was given an ultimatum I was ill-suited for operation My skin was in a poor state an old scar had broken down and refused to heal, my bladder was chronically infected, at operation the bladder which for years had been contracted, with very thick wall and a maximum content of 6 oz was found to contain 40 oz of retained urine Under local anæsthesia with all precautions, a suprapubic cystostomy was performed My blood-urea a week later was 120 The operation has achieved the maximum of success At the present time, more than two years later, I am well and independent My bladder drains through the permanent suprapubic opening by means of a self-retaining Foley catheter, which I change myself every six weeks The wound and the tube channel are healed There is no leakage and no discharge and I wear no dressing or belt For years I have worn an appliance for the prevention of double inguinal hernia, and to this my bag by day and my tube by night are fixed I have no urinary symptoms whatever For this excellent result of an operation which has not a good reputation, I owe a great debt to my surgeon There was no emotional reaction, nor any occasion therefor A good surgeon makes a good patient.

THE SETBACK

This was the great surprise of my life. I was convinced that my spinal lesion was quiescent after twenty-nine years The way in which it flared up is perhaps worth describing in detail

On Monday, July 27, 1959, returning home after a frugal lunch, I felt sleepy and sat down on an easy chair, my legs supported from knee to foot on another chair When I awoke, I could not move my left leg After waiting a few minutes, I managed to struggle to my feet, and, with the aid of my stick and the furniture, to reach the hall There my left foot trailed and I fell I pulled myself up by means of a chair, and in about ten minutes the left leg returned to normal. I walked quite normally round the lawn to the summerhouse as I stood beside it my left leg suddenly lost all its power and I nearly fell. I then, after a minute, was able to walk normally into the house, when suddenly it failed again for a minute. Thereafter, for three complete days I was in my usual health—motoring, walking, and going round a hospital. On retiring to bed after three days I found that both legs had lost power to a serious degree. The next morning I could just dress and attend to myself, and walk with short shuffling footsteps and trailing left leg, aided by my stick, across the lawn. The old spasticity in my back had returned.

I slowly improved but after three weeks my legs were completely fatigued after 100 yards After three to four months I had steadily returned nearly to my old state of health My whole technique as regards movement had to be delicately readjusted I can again walk slowly as far as ½–1 mile in a day, drive the car with ease and freedom, but am more spastic than I was I have still no idea of the cause of this setback

SUMMING-UP

This simple tale shows the unity of the human organism, body, spirit, and mind This illness, a paralysis, might have been regarded as purely physical The record shows that it excited powerful emotional reactions The emotions were diverted from their normal outlet into channels of purposive activity They stimulated the intelligence, so that the spirit and the mind, acting together, dominated the body, and raised it to the highest level that the remaining disabilities would permit. At this level, body, mind, and spirit acted in as perfect unision as in the healthy human being

There are few who would go so far as Plato and wish their doctor to have many illnesses, but this tale supports Plato's thesis that a doctor who has an illness learns the better to understand his patient's feelings and acquires a deeper understanding of his art

LVIII.—HEARTBREAK HOSPITAL

DEAR JACK,

It was good of you to send us a Christmas card, early as always, and a very merry Christmas to you, too, and to your staff, God bless them! It was in their position in that very hospital (as you probably well know) that I spent my first Christmas as a junior resident, for my sins, and whatever sins I may have had—and they were many —I reckon I just about got up to date with them there That, of course, was before they made you the Surgeon, so doubtless times have changed It was a shattering experience which haunts me still, and I'm thankful that my physical stamina (carefully nurtured by six years' studious neglect of work) got me through Let me tell you about it I need to get it out of my system

It's really not so long ago that I found myself at that loosest of loose ends where you've got no prospect of employment the next month but the mortgage has to be paid Thus it was that my desperate postal pleas reached your St Beezum's Hospital—lately the Wapchester Municipal Institution, or, as it was familiarly called, the Golden Gates of Wapchester Faltering steps led me to a great grey gaunt building, rising, all slate and dirty brick and crowned by the regulation water-tower, from a sea of monotonous black slum roofs It was enfortressed from the surroundings (? to keep the patients in) by a huge wall and gates of immense size In response to my tinklings a gloomy porter creaked them open and led me solemnly over courtyards of decaying asphalt and sterile flowerbeds and by great blocks of seemingly deserted wards—somewhat after the manner of the boatman conveying the souls of the dead across the river Styx He left me at last, alone in the residents' mess to take in a further dismal scene The room was decorated in old dark-green paint and crammed with heavy Victorian furniture a decrepit sideboard contained some battered cutlery, mats, cruet, an empty jar of piccalilli, and yesterday's *Mirror* A vast bookcase housed a few tattered *Lancets*, the Calcutta Review of Public Health for 1947, the front and back covers of *The History of the War in Pictures*, and *Anna Karenina* missing pp 638–921 There was also an empty beer-bottle and, for some inexplicable reason, volumes of the *London Companion* for 1862 to 1875, bound neatly in leather A torn and tea-stained cloth covered the table, and there were neither pictures nor fire The clock had stopped at 7 23, and the room seemed to be lit by a 10-watt bulb It seemed impossible that anyone could actually be *living* there—even the flies were dead. I turned on an elderly radio—some relic apparently of early electronic history, but the only thing I got was a strong smell of burning A crone hobbled out of the nether regions. "'Ere, can't use that, it's busted" She examined me more closely "You the new doctor? Didn't tell me you was coming they didn't, ain't got yer room ready" With which hearty greeting she disappeared into the ground

This is just the introduction, setting the scene for you, but perhaps you would be bored by all the dreadful detail—the great cold bedroom on the third floor against which a diminutive gas fire battled valiantly but in vain —the awful plumbing noises and the trains that kept me awake on the rare occasions when patients didn't—the complete lack of recreational amenities apart from the nursing staff (not that we had time)—the food, oh the food, words fail me, ghastly hashed-up reheated slosh, armour-plated fried eggs, pastry like cardboard—the endless bickering with the hospital secretary which never got us anything but promises—and the hours! Half-day a week and one weekend in three gave me about a 140-hour week, and, with salaries then £350 less £100 for the appalling living quarters that I had no desire whatever to inhabit, I was being paid at about 8½*d* an hour I suppose it was terribly good clinical experience that I shall always be grateful for and all that, but it didn't strike me that way at the time I should really have quit, I suppose, but one is very green and insecure round about the time of qualifying, and generally frightened of everybody My maturer colleagues in the mess might have made a fuss, but being largely foreign they were uncertain of themselves too It was, as you know, a busy hospital, and with two wards of 54 beds, mostly acute, I had enough to do The prospect of reading up one's cases or studying for an exam was a quite laughable one

You don't need to tell me that since then the place has been redecorated—they started before I left But those old buildings need a lot more than the odd coat of paint The coke boilers of circa 1875 won't usually stand the extra basins and radiators that make such a difference when the cold north-easter blows over the Pennines at this time of year I know, too, that teaching hospitals often offer an even rawer deal to their young chaps, secure in the knowledge that the supply of eager applicants is unquenchable It has been said, also, that your junior staff are now more numerous and that a television set will probably make their Christmas vigil a happier one, but I wonder! Is it true that you had no applications for your last H S vacancy apart from an M D (Skorblensk) of 58, reinstated by the G M C last year after a number of drug offences? If this is true (and somehow I hope it is) it might make that dreary old committee of yours see the red light and do something at last. Married quarters would solve your problem, even if it did mean more building A really solid staff shortage is the only thing, in my experience, to shift a lay committee—which is probably why so many dull old hospitals have such pleasant new nurses' homes

Let's face it Jack, junior staff have a pretty bad time of it. Not so bad as in our day perhaps, but the increase in salary has scarcely kept up with the cost of living, and the hours, even now, are often atrocious They don't usually know their rights (have your administrators shown the juniors the Ministry circular on Standards of Accommodation H M 58/68—have they? I bet!), and when they do they are too insecure and scared to make a fuss And not without reason, for it may be professional death to become known as a " trouble-maker " I wonder if your medical committee has a junior staff representative yet? This proposal has been approved by quite exalted bodies—although often the behaviour of consultants at this function is far too disturbed to exhibit before junior gaze However, a junior's presence is to be encouraged, if only to make his seniors act like gentlemen One of our splendid representative bodies, not a hundred miles from Tavistock Square, is at present trying to compose a sort of *Guide Michelin* to hospitals in the N H S, and good luck to it. The trouble seems to be that the questionary is not getting through to the very chaps that should be filling it in our region held a meeting not long ago and none of the junior staff there had heard of it It's a modest affair concerned with matters of solid fact—none of the 5-star business yet—but I hope the next edition will be more enterprising Good luck to it anyway, it is contributing, if meagrely, to the Millennium

So a Happy Christmas to you Jack—and to your staff Spare a thought for them as you carve the turkey in the bosom of your family on Christmas day, on Christmas day, on Christmas day in the morning

Your old and affectionate friend,
RICHARD COBBLEIGH.

Public Health

The Registrar-General's Commentary

IN his commentary on the statistics for England and Wales for 1957[1] the Registrar General remarks that the home population has been increasing by an average of 180,000 a year, in round numbers, since 1951, and in the twelve months mid-1956 to mid-1957 it increased by 240,000 to an estimated 44,907,000

The " natural increase " (the excess of births over deaths) was 226,000 in 1956–57—a year of high birth-rate and low mortality About 106 boys are born for every 100 girls, but the death-rates for males are higher than those for females at all ages, so at ages 0–4 there were 1053 males per 1000 females, at ages 30–34 the numbers were about equal, at ages 60–64 there were 770 males per 1000 females, and at ages 75 and over there were nearly twice as many women as men.

Births—The 723,381 live births in 1957 were the largest number since 1949, and the birth-rate of 16 1 per 1000 population was the highest since 1950 This increase continued the upward trend which began in the late spring of 1955 (The 1958 rate was higher still, at 16 4)

Marriages—There were 346,903 marriages in 1957—6000 fewer than in 1956 The decrease was due to the smaller number of unmarried persons of marriageable age in the population. The marriage-rate—15 4 persons marrying per 1000 total population—was slightly lower than in 1956 The tendency to younger marriage is reflected in the proportion of grooms and brides who are under 21 For men it rose from 3·4% in 1938 to 8 7% in 1956 and to 9 6% in 1957, for women from 16 4% in 1938 to 32 2% and 33 6% in 1956 and 1957

Deaths—There were 514,870 deaths registered in 1957, the death-rate for both sexes being slightly lower than in 1956

Infant mortality and stillbirths—The infant-mortality rate was 23 1 per 1000 live births in 1957, and was the lowest recorded in England and Wales (the 1958 rate was lower still, at 22 5) More than 60% of the deaths occurred in the first week of life, but the rate for these deaths in the first week (14 1) was also the lowest recorded in this country The stillbirth-rate of 22 5 per 1000 total live and still births was slightly lower than in 1956 Immaturity continued to be the chief cause of infant mortality

Tuberculosis—There were 4784 deaths from tuberculosis in 1957—11% less than in 1956 Deaths from respiratory tuberculosis fell by 12%, but for the first time for many years there was a small rise in the number of deaths from the non-respiratory form—from 522 in 1956 to 535 in 1957 There were no deaths from respiratory tuberculosis of boys aged 5–9 or of girls aged 10–14 Notification-rates continued to decrease, being 82 per 100,000 population for males and 49 for females Mass miniature radiography units made 3,514,600 examinations in 1957, the number of cases found by these units was 22% of all cases of respiratory tuberculosis notified The highest incidence of cases was again found among persons referred to the units by general practitioners

Cancer—Deaths assigned to cancer in 1957 numbered 94,017 (50,056 male and 43,961 female), the highest numbers yet recorded The largest increase in cancer mortality in both sexes since 1936–39 has been from cancer of the lung Cancer of the lung accounted for the highest proportion (nearly a third) of all male deaths from cancer in 1957 and for about 6% of all female deaths from cancer

Diseases of the circulatory system—In 1957 there were 188,630 deaths assigned to diseases of the circulatory system and a further 73,669 to vascular lesions of the central nervous system, which together accounted for 51% of all deaths

Accidental and violent deaths—There was a decrease in 1957 in the number of deaths due to accidents and violence, which numbered 21,561 compared with 21,870 in 1956

Registration of Food Premises

In his annual report for 1958, Dr J H. Briscoe-Smith, medical officer of health for St. Marylebone, describes a sharp outbreak of food-poisoning, involving two schools, in which 62 pupils and staff were affected The cases were spread over seventeen local-authority areas, and, apart from verbal notification of the original case, only 3 cases were notified. Had this outbreak resulted from consumption of food in a restaurant it might have remained undetected or, at best, investigation might have linked the 4 notified cases

> " the control of detected cases of food-poisoning and their contacts, though essential, is much less likely to be effective than a direct attack on the source of the infection by the close supervision of every place where food is produced, prepared, handled or eaten to ensure that every precaution is taken against its contamination.
> The registration of all food premises is long overdue and it is a sad commentary on the present state of the law that while one shopkeeper selling packaged ice-cream from a refrigerator is required to register with the local authority, his next door neighbour selling frozen foods is not required to do so Many of these foods such as made up meat and fish dishes, some of which may be prepared as far afield as Italy, are, if not stored properly, potentially at least as dangerous as ice-cream and are much more liable to contamination during manufacture."

In England Now

A Running Commentary by Peripatetic Correspondents

It is an unhappy Christmas Day tradition in most hospitals for the senior surgeon to carve the ward turkey, usually with a display of ill-concealed ineptitude both anorexigenic and alarming to any patient about to undergo surgery It is also customary to cast the pædiatrician in the role of Father Christmas at the children's party and this, too, is an unsatisfactory arrangement

To begin with, the disguise is hot and uncomfortable One frequently trips over bits of trailing robe, and wisps of cotton wool have a propensity for invading oto-oro-rhinological orifices with irritating consequences which may render inadequate control over blasphemous interjection For a few children the appearance of Father Christmas is the signal for a prolonged and piercing howl, unappeased by a chorus of a dozen shameless brats to the effect that "He's not Father Christmas at all, but that nasty doctor who gave us the needle the other day!"

Having restored some semblance of order (a semblance being all that is ever feasible on these occasions), one must then begin the dangerous business of distributing the presents The opening of the first parcel is the cue for a mad onrush of hordes of small children and, notwithstanding a bodyguard of stalwart nurses, the little horrors are liable to swamp trees, parcels, presents, Father Christmas, and everything It is an unfortunate trend of our times to provide children with all manner of warring implements, and Father Christmas at once becomes the ready target for a variety of missiles ejected from crossbows, pop-guns, catapults, water-pistols, and so on Some of the little devils are so preoccupied with fighting that they fail to answer when their names are called Then, every now and again, some juvenile impostor will claim a parcel destined for someone else, who soon raises a vociferous condemnation of this outrage To mete out justice under these circumstances merely serves to transfer noise from one source to another A final difficulty, for which there is no remedy, is that some child has to have his present last of all A prolonged wait does nothing to enhance appreciation Either he has one like it already only better, or it is the wrong colour, shape, or size, or perhaps neighbouring destructive influences are brought to bear at an early stage

Thank heaven I have seen the last of Christmas for the next twelve months

* * *

I have already spent a fortnight in bed with influenza, but I am glad to stay in for a few more days, for the weather is terrible A gale with slush and snow is blowing and everything is in disorder, because every year the winter comes as a great surprise to this country The papers are full of descriptions of 300 cars in one big mass on the main road to Copenhagen All the trains are stuck at Glostrup because the signals are frozen The ferry from Elsinore to Halsingborg cannot carry the international sleeping-cars, because they are too heavy and the ferry will tip over in the wind And a woman in Busserup had her child before the midwife arrived, late in the snow

All this makes soothing reading when you are in bed and have time to read Professor Blackett's article in the *New Statesman* I think it's time Britain and Denmark and other countries stopped making or buying atom bombs and concentrated on getting a bit of gravel on the roads to help the midwife to get to Busserup in time

* * *

Thirty years ago, my straw hat and a noisy packet of crisps held in a sweating hand, with boils on my neck, I was impelled on and down, down into the pit (9*d*) by sex, a dirty word in those days, by posters declaiming "The Eternal Eve" I huddled into the plush seat thankfully No prefect had spotted me Through the miasma of the years I still recall the pervasive smell of patchouli, those gorgeous stark Dietrich legs, the insolent heavy-lidded vulpine stare, and the soul-freezing stuff that only U F A Studios could produce—"Kiss me, my fool!" My heart bled for poor dear old Emil Jannings, haggard and humiliated, even for his fatuous *furor teutonicus* and the universal and grimy Weltschmerz

Last week my children took me to *The Blue Angel* and we sat in pseudo zebra-skin tip-ups, through a pervasive smell of Heavenly Mist But the saucy tone-deaf child-siren with flaring nostrils and android lips had little to offer, even with her race-horse legs thrown in My sour heart did not thrombose over the agitated and vulgar domestic peccadilloes The film was all too evilly refined and morbidly tiresome Yet as the lights went up a lad with boils on his neck and a straw hat in his hand hurried out I thought he looked like any other boy, but my children said he looked rather like me

* * *

Routine laboratory work may appear dull and humdrum, but it has its rewarding moments

The young, newly promoted student technician in blood-transfusion had laboriously completed his first routine examination of samples of blood from the antenatal clinic The ABO groups agreed, the Rh groups, using two different anti-D sera, agreed, and the antibody tests were also in agreement The long afternoon session was at an end most satisfactorily I turned to him and said, "That's wonderful" He sighed and, with heightened colour and sparkling eye, he replied, "It's not wonderful, it's a ruddy miracle"

* * *

Americans are an oral nation and no mistake As part of the universal milk-and-honey, there is an immense proliferation of candy, milk-bars, chewing-gum, and cigars What with Hollywood, teenagers, and baby-dolls, kissing has become the major industry and a prime raw material for export But alas! cigarettes are already under sentence, cranberries are suspect, and now another subtle blight has fallen on the unhappy land Long-suffering rats, painted year by patient year with lipstick dyes, have at last developed tumours Suddenly the American skies, the biggest and bluest ever, are darkened Lipstick is out, goodbye glamour Whatever will be the effect of it all? The women's strike fomented by that arch-shop-steward *Lysistrata* averted war, certainly, but probably only because the men were too busy arguing with their wives to fight the enemy What will happen now that oral aggression can no longer take its rightful avenue? Shall we see a bitter outburst of frustrated verbal savagery and a renewal of international discord, or will there merely be a boom in American milk-sales?

* * *

CHRISTMAS NIGHT IN THE DOGHOUSE

Nowell, nowell, nowell, nowell!
That may be what *you* say—I say what the hell
You say, Christmas comes but once a year—
What do you expect me to do about it? Cheer?
And if you do, for precisely that reason
I hereby resolve to scrub round all compliments of the season
Of robins giblets and fetch your own blooming log
As well as of all pushing characters with something to flog
As the commercial buildup gets huger and huger
Personally this person gets Scrooger and Scrooger
So resisting all those spiels
With hark the herald thank you Sirs and sticky seals
Let them, I say, decorate their tents prefabs and baronial halls
With luminous glass bodgers and little balls—
At the sight of a cracker tears
Run down my nose for all you victims of racketeers
And when I think about the lolly
Spivs make annually out of the craving for holly
Anyone who in my hearing mentions Bob Crachitt
Is going to catch it

Hark the Herald Angels sing
  Gramophones and plastic string
Rheum and reindeer, crackling, carols,
  Slipping discs, and rolling barrels
Gourmandising grub and culture,
  Christmas hastens our sepulture—
May you at this festive season
  Get the chance to name your poison

Letters to the Editor

USE OF THE TERM "SUPERFEMALE"

SIR,—I hope that nothing I say will be regarded as any reflection on the importance of Jacobs et al 's[1] demonstration of the existence of an XXX chromosome pattern in a woman with hypoplastic genitalia, but I must own to a certain satisfaction on seeing Dr Stern[2] cast doubt on the propriety of the name "superfemale" Though their letter of Dec 19 answers part of Dr Stern's objections on genetic grounds, I think from a more general point of view it is possible to criticise "superfemale" This name has the important advantages of being memorable and being inapplicable to any other syndrome, but it is frankly misleading as a clinical description Moreover, it has an emotional element which should be avoided, if possible, in the terms we use in speaking of patients with this kind of disorder Dr Stern's alternative of "metafemale" avoids the positive error but falls into the opposite one of vagueness there is a large class of cases to which the term metafemale could be applied (all the varieties of female pseudohermaphroditism, for instance) and only arbitrary definition can confine it to the sense he proposes

Surely there is a far simpler solution in the use of the chromosome constitution as part of the name? The chromosome constitution is the best definition of the syndrome, and it could simply be called the "XXX syndrome" One could similarly resolve arguments as to the names of other syndromes with chromosomal anomalies If one introduces the XXY into the name of what I used to call chromatin-positive Klinefelter's syndrome, there can be no ambiguity as to what one is talking about The "XXY syndrome" would suffice, though most people will probably prefer to use "XXY Klinefelter's syndrome" or some such phrase The Turner's syndrome complex is more difficult, simply because it is a complex, but if the results of Harnden and Stewart[3] prove to be generally applicable, it may well turn out to be justifiable to speak of "XO Turner's syndrome" for the classical cases and "XY gonadal dysgenesis" for the cases without stigmata Mongolism might well be called "22-trisomy" if we are to carry this out logically—though here, of course, we are handicapped by the absence of an agreed nomenclature for any of the chromosomes except the sex chromosomes

As Ben Jonson so wisely said, "A man coynes not a new word without some perill, and lesse fruit, for if it happen to be received, the praise is but moderate, if refus'd, the scorne is assur'd Yet wee must adventure" It *may* be premature to use chromosome constitution in definition and naming But the advantages would be great, and the risk I think slight "Wee must adventure"!

BERNARD LENNOX

NATURAL HISTORY OF CAVERNOUS HÆMANGIOMATA

SIR,—I have read many papers like that of Dr Simpson (Dec 12) advocating that cavernous hæmangiomata should be given "expectant treatment", that pompous locution for doing nothing None of them brings out two important points The first is that many dreadful disfigurements, particularly of the face, begin as tiny red spots, either present at birth or appearing in the first month Nobody knows what would happen if they were efficiently treated at this stage, since they are quite invariably dismissed as trivialities, it would be interesting to find out

In spite of preaching for years that a growing red spot on a baby's face is a surgical emergency, I have never yet had one referred to me at this stage by a general practitioner, but I have picked up a few and treated them The results suggest that the process of regression can be started very early in the growing stage by producing inflammation in the abnormal tissues

The second point is what happens to the cases which disappear from these inquiries It is undeniable that many mothers, in horror at what is happening to their babies' faces, seek the aid of surgery It would be interesting to know how many

London, W 1

DENIS BROWNE

SIR,—I read with interest Dr Simpson's article of Dec 12 It only goes to prove how misleading statistics can be, and what large numbers must be studied

All are agreed that cavernous angiomas disappear in the course of time, but they are likely to leave atrophic depigmented areas, not infrequently they undergo spontaneous ulceration which results in a cure, but the resulting scar is apt to be disfiguring

I should like to quote from a paper by Andrews et al[1]

> "The records of 1113 patients with angioma who were observed at the Columbia University-Presbyterian Medical Center between 1932 and 1955 were studied Of these, 329 had hemangioma simplex and 584 had hemangioma cavernosum Of the 153 patients with hemangioma simplex who received no treatment, 102 could be observed adequately The lesions of 64 (63%) involuted or improved within 5 years, whereas those of the other 38 (37%) persisted after 5 years Of the hemangiomas simplex which involuted spontaneously, 83% were 1 cm or less in diameter It may be concluded that any hemangioma simplex on the face measuring 1 cm or more should be treated promptly, since it is unlikely to undergo involution without therapy The danger of ulceration of hemangiomas on the lips, nostrils, eyelids and ears suggests that these should be treated even though less than 1 cm in diameter
>
> "Of the cavernous hemangiomas of 135 patients who received no treatment during the first 5 years of life and who could be followed adequately, 22 (16%) involuted or improved within 5 years The lesions of 113 (84%) persisted more than 5 years This high percentage indicates the desirability of treatment for all cavernous hemangiomas"

I think there is a great tendency to exaggerate the frequency with which congenital hæmangiomata undergo spontaneous involution and disappearance

I should also like to refer to a paper that Dr E Millington, radiotherapist at the Royal Sussex County Hospital, and I read at the Brighton and Sussex Medico-Chirurgical Society in 1953

In a survey made at the various hospitals in Sussex and Kent of 1752 cases of angiomas, 814 received X-ray therapy, the criterion of recovery being the maternal satisfaction in all cases The treatment consisted of one, two, or three treatments of 400–600r repeated at 6-monthly intervals 200 cases in the series required treatment after the 5-year period, and only 20% cleared in the first year In a personal communication, Professor Trueman-Nelson confirmed the view borne out by these results

The series by J Walter, of Sheffield, comparing 83 untreated cases with 88 treated was too small By choosing an equal number of patients at various periods in our group these figures could be confirmed and contradicted

The late Dr Roxburgh believed that although a large

number of cavernous nævi show a marked increase in size in the first 6 months of life, they usually disappeared spontaneously, but there is another less common type, quite indistinguishable, which tends to increase in size, but does not disappear at the 5th year, and indeed often increases in size at this age

If cavernous hæmangiomata are alleged to clear spontaneously how is it that so many are met in adult life?

Hove, Sussex E COLIN-JONES

INTRATHECAL PHENOL AND RELIEF OF SPASTICITY

SIR,—I wonder if I might be permitted to make a few comments on the papers by Dr Nathan and by Dr Kelly and Dr Gautier-Smith in your issue of Dec 19

Dr Nathan and Dr Kelly will, I am sure, recall that Dr Maher and I have long been interested in this particular manœuvre, for they contributed in a very agreeable and informed way to the discussion on a paper which I gave on this subject in April, 1959 Perhaps I might add that Dr Maher and I at this very moment have a paper on our experiences with this technique in the hands of the Editor of another journal

The earliest occasion in which we used this technique was in the case of a patient with a hemiplegia who was treated by Dr Maher in April, 1956, and it is quite satisfying to report that this patient is still ambulant in December, 1959 Another patient with multiple sclerosis and painful flexor spasms which made sleep impossible for her was first treated in November, 1957, and again in January, 1959, because of recurrence of the spasms This accords with the experience of Dr Nathan and Dr Kelly, who had both found that reinjection proved very helpful

We are all well aware of the disadvantages of the method I was interested to note that Dr Nathan mentions the danger of paralysing the sphincters Our experience has been that the most probable affection of bladder function is that of retention, cystometrograms in such cases have demonstrated that the bladder muscle is atonic but the sphincter is not paralysed A short period of tidal irrigation has resulted in recovery of bladder function within the space of three to four weeks in most cases of this nature, but in one of them it was necessary to resort to bladder-neck resection (Mr T Moore)

Dr Kelly finds that phenol in myodil is more satisfactory, but our experience has been that its effect is of relatively short duration, and the use of this particular combination seems to interfere to some extent with the later effect of phenol in glycerin One has the impression that the deposition of the myodil solution round the nerve-roots in some way prevents subsequent use of phenol in glycerin from producing its full effect. We have used the glycerin solution in ambulant patients, but our practice is to try 2% rather than 5% solution in such cases, in order to avoid diminution of motor power

Although Dr Nathan has found little change in the constitution of the C S F following the introduction of phenol into the theca, we have found that the protein in certain cases may rise as high as 400 mg per 100 ml, but, as he says, the meningeal response is surprisingly mild

One point of philosophical interest emerges One gathers that Dr Nathan and Dr Kelly were carrying out their clinical experiments simultaneously with our work, although they do not mention any precise dates of the cases which they describe in detail It seems that this is yet another example of the creative urge of the Zeitgeist

Manchester
L A LIVERSEDGE

SIR,—The two articles on intrathecal phenol follow closely the experience in this unit, where the original Maher technique has been used and spasms have been relieved satisfactorily

Dr Nathan pools his solution at the anterior root Dr Kelly and Dr Gautier-Smith have their patient in the lateral position, which would presumably affect both roots, but more the posterior one In a short series of mine the posterior roots have mainly been affected These differing methods have all produced relief of spasms, though it would appear that Dr Nathan's method gives a more permanent result, and this must be due to his concentrating on the anterior root In the future I think this will prove to be the method of choice in most cases, but it may well be that in those patients where an attempt should be made to conserve residual voluntary movement, a relatively " weak " phenol solution concentrated mainly on the posterior root would be best If this failed a strong solution could always be used later, on the anterior root

The following two cases are of interest The first because of a considerable recovery of voluntary power, the second because it involved the treatment of a spastic arm

(1) A woman with cervical spondylosis and bilateral severe flexion and adduction spasticity of the legs with flexor spasms A number of intrathecal blocks relieved the spasms and unmasked enough voluntary movement and power in one leg to allow her to push herself up the bed when she slid down

(2) A young man with spasticity of arm and leg after a head injury (no spasms) His fingers were digging into the palm of his hand and producing pressure sores 3 ml phenol (1 15 in glycerin) at the cervical level relieved the spasticity and uncovered voluntary movement of the hand He then had a weak but very useful grip

Finally, two questions One to Dr Nathan, who mentioned the danger of paralysing the bladder sphincters has he had any complications of this nature in his series and if so to what degree? The other to Dr Kelly and Dr Gautier-Smith it would be valuable to know their criteria for deciding what concentration of phenol to use (the range 5–20% is rather large)

I found the two articles of great interest and much value

Liverpool
S LIPTON

THE CONVALESCENT EXCRETER OF SALMONELLÆ

SIR,—In a recent annotation[1] on the treatment of salmonella carriers, you discussed the possible value of furazolidone (' Furoxone ') At that time only one clinical paper[2] dealing with this drug had been published Since then more articles have appeared[3–6] These reports are concerned with the treatment of a total of 271 patients, of which 255 became symptom-free after three to five days' therapy with furazolidone 105 were shown to be suffering from infections with one or more strains of the following organisms shigella, salmonella, escherichia, staphylococcus, streptococcus, giardia, entamœba, and proteus

4 patients who were suffering from *Shigella sonnei* infections were not cured by chloramphenicol After subsequent treatment with furazolidone a clinical and bacteriological cure was obtained In addition, the patients with the protozoal

---

[6] Rettig, J H Scientific Exhibit, American Medical Association Meeting, Atlantic City, 1959

infections (11 in number) also became symptom-free and showed negative stool-cultures after therapy. In all of these investigations no side-effects other than very occasional nausea and vomiting were experienced.

Your annotation also referred to the treatment of *Salmonella typhimurium* infections in fowls with furazolidone, and it was stated that most of the birds which survived became chronic "carriers". In human gastrointestinal infections, however, this has not been shown to occur; few patients continued to carry this, or other pathogens, after treatment.

The presence of pathogenic organisms in the stools was demonstrated in 105 patients. After treatment, 97 showed negative stool-cultures, but the remaining 8 continued to harbour pathogens.

The only work on the treatment of carrier states is by Hobson,[7] who investigated the action of furazolidone in mice made "carriers" of *S. typhimurium*. Treatment with high doses of this drug freed 8 out of 16 mice from this organism. In another group of 16 such carriers that received no treatment, only 1 mouse freed itself spontaneously from the pathogen.

TREATMENT OF BLEEDING PEPTIC ULCER

SIR,—In reply to Dr Køster (Dec. 26) may I say that:

(1) Operation is indicated if the patient has renewed massive bleeding after admission to the hospital or if such a condition continues after admission. Massive bleeding is a condition where it is impossible to keep the blood-pressure normal without continued transfusion.

(2) The age of the 6 patients who died unoperated upon was between 70 and 92. 3 patients had such a severe cardiac insufficiency that operative treatment was presumed contra-indicated for they could not even be transfused. 2 patients died in the first two hours after admission despite transfusion. Because of his age, the patient of 92 years was not operated on although he did have renewed bleeding.

Drammen, Norway.
OLAF ROMCKE

SIR,—I should like to support Mr Lytton's remarks (Dec. 26) concerning patients with melæna, but without hæmatemesis, and in whom no diagnosis is made.

An identical case to Mr Lytton's was treated in this hospital in 1957, and another stomach was lost needlessly, the bleeding coming from a small hæmangioma about 0·5 cm. in diameter, involving the anti-mesenteric border of the jejunum about 4 feet from the duodenojejunal flexure.

This man, aged 45, was admitted in November, 1957, with a severe attack of melæna of 3 days' duration, with no associated dyspepsia. Transfusion was undertaken, but further heavy melæna produced unconsciousness which recovered with subsequent rapid transfusion.

At laparotomy on Dec. 15 no abnormality was found, but the jejunum and ileum were full of blood. A blind partial gastrectomy was undertaken, but the bleeding continued and it was decided to undertake a further laparotomy on Dec. 20. On this occasion there was blood only in the ileum, and a small jejunal lesion was indicated by a leash of vessels running towards the acute mesenteric border, but no underlying thickening or ulcer could be felt. Resection was undertaken and the lesion proved to be a necrotic jejunal hæmangioma.

His subsequent progress was uneventful, apart from the development of an incisional hernia, and when he was last seen several months ago his general condition was excellent.

In this case there had been a careful search of the small intestines, but the lesion was missed on the first occasion. On the second occasion it was relatively easy to find the lesion as the jejunum was empty of blood.

Hackney Hospital,
London, E.9.

ORAL HYPOGLYCÆMIC AGENTS

SIR,—In your leading article of Dec. 19 you wonder whether early enthusiasm has made too light of the disadvantages of these drugs, using insulin as a standard of reference. This may be so, but I feel it equally pertinent to wonder whether we are too complacent in our attitude to insulin. Insulin is not satisfactory replacement therapy in diabetes, such as thyroid is in myxœdema or as cortisone is in Addison's disease. It could more closely be compared to the use of folic acid in pernicious anæmia. Insulin has saved and prolonged the life of thousands of diabetics but at the same time it permits the development of the most devastating complications, even in so-called mild diabetics. I have observed that some diabetics whom we have designated as "failed tablets", because while taking tablets their blood-sugars remained above normal, showed equally poor control when transferred to insulin. But we were more prepared to accept hyperglycæmia in these patients on insulin, because even if the treatment were unsatisfactory, at any rate it had nearly 40 years of orthodoxy behind it. Whether hypoglycæmic agents will be more or less effective than insulin in preventing long-term complications in "mild" cases remains to be seen.

There are two aspects of oral hypoglycæmic agents not treated in your leader that I feel are worthy of mention.

First, in many new diabetics who initially fail to respond to diet alone but who are controlled by tablets, remission of the diabetic state occurs after normoglycæmia has been maintained for about six weeks or so. If the tablets are discontinued after this length of time, in many diabetics good control continues on the same or a greater diet than was originally ineffective. In my opinion, newly diagnosed diabetics should not continue to take tablets indefinitely without establishing at some point that a remission has not taken place.

Second, since the sulphonylureas and the diguanides have a different mode of action, some diabetics who cannot achieve normoglycæmia on either preparation alone may do so on a combination. A combination of chlorpropamide and phenformin is the most effective oral hypoglycæmic therapy available today.

Finally, you state that the risks of toxicity seem to be less common with chlorpropamide than with tolbutamide. I feel wider experience with chlorpropamide is necessary before this can be substantiated. Sensitivity drug rashes are commoner with chlorpropamide, and whereas the therapeutic dose of tolbutamide can be exceeded with impunity, increasing the daily dose of chlorpropamide above 500 mg. daily can give rise to jaundice and vertigo, suggesting a narrower margin of safety than with tolbutamide.

London, W.1.
ARNOLD BLOOM

DENTISTS AND ANCILLARIES

SIR,—Your annotation of Dec. 5 may lead some readers to suppose that there is a shortage of candidates for training as dentists. This is not so. Candidates commonly apply to three or four schools in the hope of obtaining a place at one of them. The serious situation is that the number of places available annually in the United Kingdom is only about 620 although the need is for at least 900.

We anxiously await the fulfilment of the Government's intention to increase the number to 890 and trust that replacement of the cramped and obsolete buildings of dental teaching hospitals will no longer be delayed.

PENICILLIN IN LEPTOSPIROSIS

SIR,—In your columns Dr Semple [1] criticised previous letters [2] [3] which suggested that penicillin is of value in the treatment of leptospirosis He referred to his own article [4] in these terms " The fact remains that a properly controlled trial has been done The only way in which this can be refuted is to show some fundamental defect in the trial, or to produce contrary evidence from another equally or better controlled series "

The report of this trial contains only one detailed set of figures for scrutiny These are in the form of a scatter diagram showing the day of illness on which the treatment was started, and the day on which patients became free of signs and symptoms (which are not further defined) Analysis of this diagram (see table) shows that the control group and the group treated with penicillin did not differ significantly in the time at which treatment or observations commenced, but that the duration of signs and symptoms was significantly shorter in the penicillin group

ANALYSIS OF CLINICAL TRIAL OF PENICILLIN IN LEPTOSPIROSIS

Group	Number	Treatment	Day treatment started		Day free of signs and symptoms	
			Mean	Standard deviation	Mean	Standard deviation
A	31	Control	4 0	1 7	7 8	2 7
B	21	Penicillin	4 7	1 2	6 0	1 8
			P>0 10		P<0 02	

The figures calculated from this diagram do not agree with those given in table III by Dr Fairburn and Dr Semple, presumably derived from the same data There the duration of signs and symptoms for the control group is given as 10 8 days, and for the penicillin group as 9 7 days Does the ordinate in the diagram perhaps refer to duration of signs and symptoms after treatment? If so it does not say so, and in any case the figures should then be 11 8 and 10 7 days respectively This difference approaches, but does not reach, significance at the 5% level. " Duration of signs and symptoms " seems a very subjective criterion on which to base an assessment, and one would like very much to study similar scatter diagrams showing total duration of fever and duration of fever after treatment

The distribution of serotypes in their control and treated groups is quite different Indeed, in more than half of the control series the infecting serotype remained unidentified The clinical severity of the diseases produced by different serotypes varies greatly It seems reasonable therefore to demand that studies of the efficiency of treatment should concern a single serotype, or that the groups compared should have a similar distribution of serotypes This is a difficult criterion to satisfy, as identification of the infecting serotype is never available until at least some weeks after the patient's admission It is, however, of interest that Dr Semple applied this criticism to the series of Mackay-Dick and Robinson,[5] but not to his own paper

It is contended, therefore, that the results reported by Dr Fairburn and Dr Semple do not justify their sweeping conclusions that " penicillin and chloramphenicol play no useful part in the treatment of uncomplicated leptospirosis in British troops in Malaya, and we suggest that these antibiotics are unlikely to be of value in the treatment of leptospirosis elsewhere ", because (i) their groups are not comparable in serotype distribution and (ii) even so, their figures can be used to support the value of penicillin if one ignores some inconsistencies in them

Clinical experience in North Queensland, supported by analysis of 264 cases,[6] is in complete agreement with the opinions of Mackay-Dick and Cook that penicillin is of value The practitioners in the area, when approached in 1953, considered that it was not justifiable to withhold treatment from patients It was not, and will not be, possible therefore to attempt a controlled clinical trial The same situation may well apply in other areas where leptospirosis is a common disease It would be most desirable that the detailed figures of the clinical trial reported by Dr Fairburn and Dr Semple should be submitted to tests of statistical significance

Medical Research,
Brisbane, Australia

R L DOHERTY

***Dr Doherty's letter was shown to Dr Semple and Dr Fairburn and their reply follows —ED L

SIR,—We should like to comment on the points raised by Dr Doherty and also to quote some of the statistical results in our controlled trial on the treatment of leptospirosis [4]

(*a*) The relevant symptoms and signs were recorded carefully every day on a standard chart by the same two observers The point at which they had ceased is a good guide to the length of the illness and marks the time when the patient is beginning to get up and about These are not merely " subjective criteria " therefore

(*b*) Any confusion over the ordinate of the scatter diagram can be clarified by consulting the text of our article [1] under the Results section the ordinate being " the day on which the patient became free of symptoms and signs after the start of treatment " If the mean results from this diagram are added to the day treatment started (table II), then the total duration of symptoms and signs will be overestimated by one day, because there is a day of illness common to both figures We consider this is the reason for Dr Doherty's thinking the figures in table III to be incorrectly quoted

(*c*) Dr Doherty has shown that the time to become free of symptoms and signs from the start of treatment is significantly shorter in the penicillin group Because this does not take account of the day of the illness on which treatment was started it is not possible to assess reliably whether penicillin has shortened the total duration of the illness The first treatment day in each individual patient cannot be ignored on the grounds that there is no statistical difference between the mean day of the illness when treatment was started in the control and penicillin groups Indeed analysis of our results [4] (table III) showed that there was no significant difference between the control and penicillin groups as regards total duration of symptoms, signs and the total time to become free of both symptoms and signs (P > 0 1 in all cases)

(*d*) We found a similar pattern as regards the length of pyrexia We first compared the duration of fever in hospital of the penicillin and control groups—this relies solely on the day-to-day taking of the temperature and on no " subjective criteria " The mean difference between the two groups was only 1 5 days (penicillin the shorter), and this was not statistically significant (P > 0 1) By adding the days of illness before admission, and presumably then getting an estimate of the total length of fever, there is still no significant difference between the two groups (P > 0 05) There is, however, a significantly shorter period of fever after treatment, but this again does not take into account the time at which treatment was started in the illness, as in section (*c*) above

To sum up, our statistical results showed that penicillin did not significantly *alter the natural course of the disease* when compared with the controls and those treated with chloramphenicol Also, as pointed out in our trial [1] (table IV), even when treatment with penicillin was started early (before or on the 4th day of the illness) the average length of the illness was *not* shortened, in fact, the average number of days taken to become symptom-free and sign-free was greater when treatment was started early We do not, therefore, see any inconsistencies in our results and believe that it would be wrong to use Dr Doherty's analysis of our scatter diagram to support the use of penicillin in leptospirosis

---

[1] Semple, S J G *Lancet*, 1959, ii, 289
[2] Mackay-Dick, J , Robinson, J F *ibid* 1959, i, 100
[3] Cook, A T *ibid* , 1959, ii 81
[4] Fairburn A C , Semple, S J G *ibid* 1956, i, 13
[5] Mackay-Dick J , Robinson, J F *J R Army med Cps* 1957, 103, 186
[6] Doherty, R L *Austr Ann Med* 1955, 4, 53, *ibid* 1956, 5, 23

(*e*) Now, as to leptospiral serotypes it is not possible to arrange an equal distribution between control and treated groups Dr Doherty feels that in a study of the efficacy of treatment there should be a similar distribution of serotypes, as he believes the clinical severity varies with the infecting serotype Trimble[7] in an analysis of 236 cases in Malaya showed that there was absolutely no correlation between clinical severity and serotype Analysis of our own results[1] also showed that the severity of the illness and the incidence of complications bore no relationship to any serotype or serogroup This, combined with the knowledge that as far as we know, all serotypes are sensitive to penicillin,[8] makes it unnecessary, even though desirable, to ensure an equal distribution between treated and control groups It does not support Dr Doherty's contention that the results of our clinical trial should be rejected because of this unequal distribution We agree, however, that it invalidates one particular criticism previously made concerning the use of controls from another time period[9] Nevertheless we still feel that in a clinical trial of treatment in leptospirosis it is desirable that controls and treated patients should be selected in a random manner and compared at approximately the same time period by the same observers—even when, as in this instance, it results in an unequal distribution of serotypes

We do not think that there is anything " sweeping " or inaccurate in our statement[4] that " penicillin and chloramphenicol play no useful part in the treatment of uncomplicated leptospirosis in British troops in Malaya " Our reasons are as follows (1) Penicillin (or any other antibiotic) has never been shown to affect the mortality of the disease nor the incidence of the complications, jaundice, oliguria, or anuria[4 10 11] (2) In our controlled trial[4] there was no significant effect of penicillin on total duration of pyrexia, symptoms, and signs as compared with the controls The mean results show that the length of illness was slightly shorter in the penicillin group The well-recognised variability of leptospirosis, common sense, and our statistical analysis suggest this a chance finding If it was real and due to penicillin it was marginal and of doubtful value, especially when balanced against the discomfort of frequent intramuscular injections over several days and the other disadvantages of massive antibiotic therapy Above all, it is in complete disagreement with the reported dramatic effects of penicillin elsewhere[12] and makes nonsense of any suggestion that controlled trials are unjustifiable in this instance

THE ABNORMAL APPENDIX

SIR,—In his article of Dec 26 Mr Jewers referred to my work on this subject His thoughtful paper confirms the two conclusions at which I arrived in 1952, namely

(1) There is no such thing as the " conservative treatment " of appendicitis If one ever considers conservative treatment it is in relation to peritonitis and never to appendicitis, which is a different thing The treatment of appendicitis, when the necessary facilities are available, is to remove the appendix. The only condition under which conservative treatment is logical is where the inflammation has spread beyond the appendix and peritonitis is present, the decision then for operation against conservative treatment being a nice one to be made with every ounce of the surgeon's lifetime's experience

(2) Appendix abscess is now the most dangerous of all the situations resultant on appendicular inflammation.

London, W 1
W SKYRME REES

EVENING COLIC IN INFANTS

SIR,—Professor Illingworth's views on the management of screaming infants are of considerable importance to family doctors In his report (Dec 19) on the trial of dicyclomine hydrochloride in evening colic in infants he shows that, of the 15 babies who received active drug and inert substance, each for a week, 9 had higher scores with the drug, 3 had equal improvement with drug and control, and 3 improved more with the inert substance than with the drug There were also four scores of +3 and two of +2 with the inert substance

Do these figures really justify his conclusion that the drug is of considerable value ?

St Mary Cray, Kent
E TUCKMAN

VASODILATOR DRUGS IN OCCLUSIVE VASCULAR DISEASE OF THE LEGS

SIR,—The conclusions arrived at by Mr Gillespie[1] cannot be allowed to go unchallenged

Mr Gillespie measured the blood-flow in the foot and calf of patients with and without obliterative arterial disease after intravenous injections of four so-called vasodilator drugs He concluded that, as the vasodilators he used did not increase the calf-muscle blood-flow and often decreased it, all prescribing of vasodilators for the treatment of intermittent claudication is useless The vasodilator drugs he used were tolazoline (' Priscol '), phenoxybenzamine (' Dibenyline '), chlorpromazine (' Largactil '), and promazine

I have found that tolazoline is the least active peripheral dilator used in my series, and I have abandoned the use of phenoxybenzamine in the treatment of obliterative arterial disease Chlorpromazine and promazine are not claimed by the makers to have any benefit in the treatment of this disease By contrast, I have repeatedly shown[2] that spasmocyclone (' Cyclospasmol '), nicotinyl alcohol tartrate (' Ronicol '), and azapetine (' Ilidar '), used alone or in combination, are the drugs of choice in the treatment of peripheral vascular disease It is ridiculous to condemn the action of satisfactory drugs on the basis of tests carried out with ineffective ones In practice vasodilators are used either by mouth or by intra-arterial injection, and not intravenously If Mr Gillespie wished to disprove the action of vasodilators in the treatment of peripheral vascular disease, he should have used them in this way

The symptoms of occlusive arterial disease develop rapidly after the disease has been present for some years A minor decrease in the blood-flow must finally precipitate the first symptoms The effective vasodilators increase the blood-flow sufficiently to ameliorate these symptoms The method used by Mr Gillespie to measure the blood-flow is not sufficiently accurate to detect small increases in the blood-flow

The long-term effect of drugs in the body cannot be assessed accurately by any method other than clinical trial The vast number of publications describing the advantageous clinical action of the various vasodilators is evidence of their value in the treatment of peripheral arterial disease

HERPETIC WHITLOW

SIR,—We read with great interest the article in your issue of Nov 21 by Dr Stern and his colleagues on herpetic whitlow amongst the nursing staff in a neurosurgical unit We encountered somewhat similar cases of herpes simplex in the nursing staff a few years ago at a London hospital,[1] but, in addition to cases of whitlow and paronychia as described in this article, there were a few cases of an impetiginous type of infection At first the lesions were like a bullous impetigo, although rarely we noted a small herpetic vesicle in the early stages After that the lesions were more granulomatous like orf and ran a more indolent course than the pyogenic counterpart We also found a distinct difference between primary and recurrent or, more probably, reinfections

Primary infections, confirmed by virological and serological tests, invariably developed multiple lesions, but, unlike the cases described by Dr Stern and his colleagues, we found a constitutional disturbance, fever, and regional adenitis to be common In one of us who developed a primary infection as a result of collecting material for diagnosis from a case of herpetic gingivostomatitis a series of small vesicles appeared four days later around a minute skin abrasion, and after a period of about a week developed into a multilocular vesicle which subsequently took on the appearance of a granuloma Pyrexia (100–101°) lasted for several days and regional adenitis was marked In two cases of recurrent or reinfection in members of the staff with herpes-neutralising antibody at the time of onset, lesions were strictly localised to a single vesicle on the thumb or digit with a small area of surrounding erythema It was also noted that this type of lesion healed very much more rapidly than the primary

In all instances a clear history of contact existed, there being cases in the ward of generalised herpes simplex or eczema herpeticum A senior nurse who developed a solitary lesion on the finger was also subject to recurrent labial herpes, but in this instance it appeared that it was not an autogenous infection but she had become reinfected from one of the cases of eczema herpeticum In this latter disease the virulence of herpes virus seems to be enhanced by the patient's eczematous diathesis, and the infection is often alarming, sometimes fatal, and compared with other forms of herpes in a non-eczematous patient the risk of contagion is greater

We also found the examination of smears taken from the base of the vesicles to be of value in diagnosis The typical appearance of multinucleate epithelial cells, which are seen only in herpes simplex or varicella-zoster infections, enabled a diagnosis to be made within a few minutes, which could then be confirmed by further laboratory investigations

HYPOPARATHYROIDISM WITH STEATORRHŒA

SIR,—In view of the occasional interest shown in the combination of hypoparathyroidism with steatorrhœa (e g , by Williams and Wood[2]), particularly since we drew attention to it in *The Lancet*,[3] it is only right that I should report the conclusion to the story of our first patient[4]

Shortly after our report[3] appeared she returned to hospital with masses in the abdomen, which were found at laparatomy to be lymphomatous This malignant growth had virtually replaced the whole pancreas and infiltrated the wall of the small bowel throughout its entire length She died shortly afterwards outside hospital and no necropsy was performed

The fact that the diagnosis of her malady was not idiopathic steatorrhœa, as we had suspected, makes no difference to the interest in its connection with hypoparathyroidism—the combination apparently including the symptom, "steatorrhœa", rather than any particular basic disease

W P U JACKSON

CRANBERRIES AND THANKSGIVING

SIR,—In the issue of *The Lancet* of Nov 28, 1959, in the column devoted to Public Health (appearing two days after our American Thanksgiving had been observed in a literal welter of cranberry sauce), a comment on both cranberries and Thanksgiving is to be found

In regard to the warning issued by the Secretary of Health, Education and Welfare pertaining to contaminated cranberries, it is pertinent to observe that Mr Flemming, in calling attention to the situation, was doing only what the law requires, and Americans, as is well known, are a law-abiding people The fact that a person would need to eat 15,000 lb of contaminated cranberries daily for a long period to suffer any ill effect is a poor argument, many persons on this side of the Atlantic would gladly do so in order to defend a principle

In the very first paragraph, in reference to the background of Thanksgiving, the suggestion is made that many of the Pilgrims failed to survive their first American winter and that those who did survive accomplished this feat because of a bountiful harvest The sad fact is that the Pilgrims set foot on Plymouth Rock on Dec 21, 1620, too late to harvest a crop that had not been planted, and that those who survived did so because of a mild winter, the friendliness of the still unconditioned Indians, and the British guts that they brought with them

Boston, Mass Editor, *The New England Journal of Medicine*

EMERGENCY RESUSCITATION IN RUPTURED ECTOPIC GESTATION

SIR,—Mr Azie[1] has done well to direct attention to a method of resuscitating patients who are gravely ill from massive intraperitoneal hæmorrhage, and for whom blood-donor or blood-bank facilities are not available This is the simple but strangely neglected procedure of injecting the patient's own blood back into the veins after straining off all obvious blood-clot Autotransfusion, as it has been called, is particularly useful in the graver cases of ruptured tubal pregnancy

The method is, however, by no means new Dr Logan,[2] working in a South African mission hospital, has recorded 40 cases of autotransfusion with recovery in every case Dr Markowski, working in Belize, British Honduras, has given me details of 100 cases of ectopic pregnancies so treated with survival in all but 1 case So useful has he found this method that he has sterile apparatus, including a mechanical sucker, constantly available in his operating-room The subject is discussed in Munro Kerr's *Operative Obstetrics* (6th ed , p 761)

During the past 25 years I have used autotransfusion on many occasions It is easy and can be used without the time-consuming matching and cross-matching of bloods Working in a teaching hospital, I feel it a duty to demonstrate the method from time to time in order to impress upon students that this is a possible way of saving a patient's life when blood-banks and blood-donors are not available

Mr Azie does not appear to use any anticoagulant when collecting the blood Were he to do so he would find that the

---

[1] Azie, A A *Lancet*, 1959, ii, 1093
[2] *S Afr med J* 1949, 22, 793

method is even easier and more reliable My practice has been to cup the blood out of the abdominal cavity by means of a small gallipot, to strain it through several layers of gauze in a glass funnel, and to collect the fluid portion in a sterile flask containing 2 g disodium citrate and 3 g dextrose in 120 ml water (the normal "bleeding" flask kept for blood-donors) As soon as the first bottle is ready it is connected to the intravenous-saline drip apparatus which has been set up before starting the operation

Naturally, only recently shed blood is suitable, but it is in the most urgent case of all—the ruptured ectopic pregnancy with massive intraperitoneal bleeding—that such blood is abundantly available The method is less applicable, but is also less necessary, when intra-abdominal bleeding has already been present for several days

It is strange that this simple procedure, which can be lifesaving in so many instances, is not better known Perhaps the present-day availability of donor blood has made our younger surgeons contemptuous of the older and simpler methods of transfusion

PRECORDIAL CATCH

SIR,—Allow me to add to the letters on the precordial catch—letters which may illustrate Dr Asher's thesis that naming a condition brings it into clinical existence I have no evidence to submit, but I should just like to record the naïve assumption that this pain is caused by some "catch" (a transient wrinkling, friction, or folding) of the pleural membranes

Amsterdam.

P J THUNG

URINARY INFECTION IN THE NEWBORN

SIR,—I was very interested in the paper by Dr James (Dec 5) I have been about to start a similar study and among other things had hoped to see if there was any correlation between cell-counts on uncentrifuged urine and the approximate cell-count per high-power microscopic field on centrifuged urinary deposit as used in most laboratories Did Dr James make any observations on these lines?

There has been an unusually high incidence of urinary infections in newborn infants in recent months hereabouts, fortunately none fatal In one infant considerable jaundice and anæmia occurred, which appeared to be hæmolytic in origin, and as we were unable to find evidence of blood-group incompatibility or other cause for the hæmolysis, we attributed this to the renal infection, the hæmoglobin and bilirubin on admission on the 10th day of life were 11 3 g and 10 mg per 100 ml, the latter rising to 15 mg on the 11th day, and the former falling to 6 3 g on the 29th day Another infant had moderate jaundice and anæmia, again presumed due to the renal infection. It would be interesting to know if any of Dr James' cases showed hæmolytic anæmia

With regard to the mode of invasion of the urinary tract, it was suggested by Delaney[1] that in addition to the hæmatogenous route, infection may spread along the lymphatics to the kidneys, or ureters, from an infected umbilicus The first infant mentioned above had a severe omphalitis, and the organism cultured both from umbilicus and urine was of the coliform group It is remarkable that the three infants reported by Delaney with omphalitis and pyelonephritis each developed kernicterus, apparently unassociated with blood-group incompatibility

Few will disagree with Dr James that treatment of urinary infections should be continued for not less than six weeks, with regular follow-up for a year or longer I presume from her use of a fairly large dosage of sulphonamide for the first two weeks that Dr James believes the main lesion in most cases of urinary infection to be pyelonephritis, an adequate serum level of the drug being required to combat the interstitial renal infection such is certainly my view

INFLUENZAL ENCEPHALITIS

SIR,—In his letter of Dec 19 Dr McGill may be ascribing to corticosteroid therapy ("modern antiallergic therapy") what is in fact the natural course of the disease In the 2 cases I reported during the epidemic[1] the most striking clinical features were the severity of the illness and the unexpected rapid recovery We did not use cortisone but only antibiotic cover Our first case was in extremis for 3 days and the prognosis seemed quite hopeless A very similar course was shown by case 2 of Dunbar et al[2]

Of the 4 cases reported by McConkey and Daws[3] only 1 was treated with cortisone, and, although they noted "some clinical improvement" 4 hours after commencing therapy, she apparently remained in coma for a further 5 days and then "recovered consciousness rapidly" It is hard to believe that the cortisone played a major role in the course of her disease

V DUBOWITZ

INSULIN REACTION AND DIABETIC RETINOPATHY

SIR,—It is accepted that well-controlled diabetic patients have less vascular complications than those under poor control Patients are sometimes observed, however, whose vascular complications become progressively worse in spite of the ideal control of their illness with diet restriction and insulin On the other hand, patients are seen who have had free diet and no insulin with no vascular complications

We observed a 60-year-old man whose diabetic retinopathy appeared after insulin reactions,[4] and another whose retinal hæmorrhage occurred during a urine-sugar-free period on insulin treatment. The experiment of Dunner et al,[5] which demonstrated that insulin produced retinal hæmorrhage in dogs, supports the possibility of the occurrence of such undesirable changes in the retina as observed by us Fortunately, I found the recent article of Jahnke[6] about the unpleasant effect of insulin on the retina He quoted several cases from the literature in which insulin seemed to provoke retinal changes He pointed out that diabetic retinopathy has been increasing with the spread of insulin treatment, and that this increase is not merely due to the prolongation of survival of diabetic patients by the progress in treatment.

We speculate that the unfavourable effect of insulin may be due to an increased release of adrenocortical hormone, resulting from a fall in blood-sugar Administration of cortical hormone or corticotrophin sometimes provokes microaneurysms and other changes in the retina The recent studies of Saito et al[7] again confirmed an increase in urinary corticosteroid excretion in diabetics with vascular complications, compared with those without complications Basing his views on the experiments of Müller and Petersen,[8] Jahnke proposed increased permeability of the blood-vessel wall I feel that the strictly controlled state, where hypoglycæmia may occur, is harmful to diabetic patients, especially to those with retinopathy

Philadelphia YOSHIO GOTO

OBESITY

SIR,—Professor Yudkin's article of Dec 19 throws much light on the confused subject of obesity Further clarification of the use of the term " overweight " and of the effect of excessive food intake seems desirable

Overweight is determined by comparison of weight with accepted standards for age, height, and sex It is a statistical concept, objectively determined by physical measurement and it is not constantly correlated with obesity Obesity is basically an æsthetic, or at least clinical, concept, subjectively determined and produced by the distortion of body contour by fat

I found in a series of 200 adult male patients seen consecutively in general practice that 3 muscular men were 40% over standard weight for age and height they were certainly not obese Similarly those with poor muscular development can be little overweight, or even of standard weight, and yet be obese Clinical judgment, not comparison of weight alone, establishes the presence of obesity.

Common experience challenges the statement that " it is simply not true that most people—or any single person—can eat more food or less food without changing weight " Dodds,[1] in a discussion on obesity at the Royal Society of Medicine, referred to an experiment in which subjects whose weight had been constant for many years were kept in bed and given two or three times their normal diet They did not increase in weight although controls put on weight easily Such an observation seems very credible and it would be interesting to know whether it has been confirmed. There is nothing inherently improbable in the idea that certain people—even most people—are able to respond to excessive food intake by increased metabolism I have not found in Professor Yudkin's article the evidence that this is not so

London, W 2 JOHN McMULLAN.

DIMINISHED RESPONSIBILITY

SIR,—Dr Maddison (Aug 15) advocates the doctrine of determinism The " argument in brief ", on its behalf, is that " the path which we take is unswervingly determined by our personality structure " In other words, we are determined, because we are determined This " argument " contrasts unfavourably with the three proofs for free will

Firstly, intellective consciousness apprehends immediately and experimentally, in the concrete, not only the act of will, but also its freedom While we are deliberating or taking counsel, and while we are terminating our deliberations or consultations, we are quite conscious that the selected end is imposed on us by our own will, and that we are not irresistibly or necessarily drawn to it Our intellective consciousness clearly distinguishes the action to which we are determined, from our free acts When someone says " tree ", I am necessitated to exercise an act of apprehension of " tree ", and I have no consciousness of freedom But when I go for a walk, or draw a line, I am conscious of acting from free choice, and that I can freely stop at any point This immediate experimental evidence cannot be met by simply denying freedom Nor can it be explained as mere ignorance of cosmic forces and laws

Secondly, there are facts which cannot be explained unless freedom of choice be admitted These include the making of plans, promises, and appointments, legislation, self-approbation, self-reproach, and remorse, the giving of commands and prohibitions, advice, rewards and punishment, praise and blame We can act against our physical inclinations, as when we refuse a chocolate lest we overeat, or when we get out of bed early on a cold morning to go to Church Surely the latter is not accounted for by a church-organist among my human ancestors, nor by a bat-in-a-belfry among my pre-human ancestors (if any)

The third and greatest proof of freedom, from the objective infinity of the human intellect, is too long for exposition here.

Because there are things in man which are chemical and material, therefore everything in man is chemical and material, and because man is pre-moved, therefore he is also predetermined, is neither good logic nor good science " As if we were villains of necessity, Knaves, thieves and liars by spherical predominance, drunkards, liars and thieves by an enforced obedience of planetary influence! " Winston Churchill gave even shorter shrift to the *spiritless deterministic* psychiatrists, in vol IV of *The Second World War* The opinion of the regimental sergeant-major, about the recruit " determined " to keep out of step, was unprintable—but justified

Dr Madison says that " the existence of ' good ' and ' bad ' " are " products of the human mind " So the apple which I threw out was not really bad, but I was bad-minded And " the facts of morality " are merely " products of the human mind " Which means that respecting my neighbour's property is not good in itself, nor is thieving bad in itself But only as my mind, or the mind of a dictator, makes them!

However, there is hope for Dr Maddison yet He introduces " accountability ", which is not accountable except from free will And he contradicts his own doctrine by informing us that " civilised man naturally assumes responsibility for the effects of his action on others "

Sydney V J KINSELLA

POSTCOITAL EXAMINATION OF SEMEN

SIR,—*I was deeply perturbed by Mr. Dunn*'s letter in your issue of Nov 28 The investigation and treatment of subfertility, especially in the male, have made considerable advances in the past ten years, and if we accept Mr Dunn's arguments and methods we shall deprive our patients of the help they can expect from us

First of all, I should like to challenge the assumption that subfertile men cannot be improved Since the time when we began to realise the importance of testicular temperature regulation, and the effects of its disturbances upon spermatogenesis, it has become a commonplace to see subfertile men recover A letter such as this is not the place for extensive explanations and references, but *I shall be glad to supply* the latter to anyone interested For the present I will only say that I have not met anyone with *personal* experience of these methods who maintains Mr Dunn's and his authorities' traditional pessimistic outlook

If it is true that subfertile men may be improved, then obviously a precise and consistent method of semen examination is essential in assessing the patient's original state and progress This, of course, requires seminal specimens produced by masturbation or coitus interruptus, and there is no adequate alternative The method of " postcoital urethral drainage " may not have been described in the literature, but *I have met* with patients investigated in this way repeatedly One such case was sent to me with an inquiry whether his apparent sterility was beyond repair, a proper semen test showed him a highly fertile man, and his wife conceived promptly after correcting a minor fault on her side Another man investigated in this way had prolonged courses of hormones and vitamins intended to cure his " oligozoospermia " Finally he was given a hopeless prognosis, but a proper semen test also showed perfectly normal findings The postejaculatory urethral residue is in no way representative of a man's fertility and any verdict based upon it must be regarded as guesswork

The postcoital test has been in constant use for many years, and I think one may regard it as a sine qua non in the investigation of an infertile couple After all, the first requirement for fertilisation is a dense and active sperm population in the cervix, and without this further gynæcological investigation may be a waste of time But despite its very great value, this test has its limitations Unless we are quite clear as to what it can and cannot tell us even a perfectly conducted postcoital examination may mislead us disastrously Mr Dunn's statement that failure to find spermatozoa in two postcoital tests suggests an azoospermic husband is truly alarming! I see amongst my patients quite regularly couples who produce persistently "blank" postcoital results, despite good semen, œstrogenic mucus, and apparently perfect sex function these are cases of a purely "mechanical" failure of insemination, and there are quite a number of reasons why this may happen Some uterine displacements may turn the cervix into one of the fornices, shielding it from the ejaculate, the couple may use a coital position making for poor penetration, a parous vagina may be so lax that the ejaculation takes place into a pocket of loose mucosa and sperms never reach the cervix, the man may have a hypospadias, and so on. A complete list would overburden this letter, but anyone familiar with the postcoital test will be aware of the problem. Incidentally, the correction of these faults usually proves very simple, once the diagnosis is established

---

[1] Dodds E C *Proc R Soc Med* 1950 43, 313

I must also raise some criticism of technical details of the postcoital test as described by Mr Dunn

Firstly, to remove only a drop of cervical mucus with artery forceps may produce very misleading findings I usually aspirate the whole contents of the cervical canal, and time and again I find some portions of the mucus poorly invaded, or even "blank", when other portions may be teeming with active spermatozoa Therefore poor findings in only one drop of the mucus may be of no significance

Secondly, for the same reason, it is patently impossible to estimate the husband's sperm density from even a complete aspirate of the postcoital mucus since we should not know which of the variedly populated fractions is representative

Thirdly, it is useless to attempt an estimate of the husband's sperm morphology from even a stained postcoital preparation. Only the best spermatozoa invade the mucus since most of the abnormal forms are either immotile or sluggish In the past, when I used to stain my postcoital specimens as a routine I frequently found in them no more than 3–4% of abnormal spermatozoa, even when the direct semen test might show up to 40–50% of morphological abnormalities I believe this is generally recognised by workers who use this method

Lastly, it is surprising to see the statement that in the postcoital test "occasionally motile spermatozoa are seen after sixteen hours" Many of us have seen excellent postcoital results 2–3 days after intercourse, and a few live spermatozoa even after 6 days. Most of my own routine tests are done 10–16 hours after coitus, and personally I am inclined to regard a postcoital test after less than 2 hours as of doubtful value. For what we want to learn from this test is whether good numbers of healthy spermatozoa survive in the cervix after being exposed to the hazards they must encounter And after 2 hours or less many spermatozoa may still be alive which will never reach the cervical canal, or survive in it if they do

One might scrutinise the reasons for introducing these indirect and roundabout methods instead of the well-tried direct semen test Mr Dunn mentions moral standards and overlooked sensibilities The former, I should say, would apply only to certain religious denominations To many men the act of masturbation or coitus interruptus, in a most worthy cause, is not more a moral issue than the gynæcologist's examination is to their wives As to sensibilities, one might ask whether a man who feels deeply would expose his wife to embarrassing and sometimes painful investigations before eliminating the approximately 40% chance that he himself carries the main infertility factor Among my own series of over 12,000 husbands the incidence of complete azoospermia is little short of 10%, and that of grossly impaired semen very much higher It is obvious therefore that failure to assess the male factor accurately would condemn many women to a great deal of unnecessary investigation, discomfort, and eventual frustration My personal impression is that usually a man's reluctance is based upon fear of being found at fault This, I think, applies equally to women, yet we do not hesitate to examine them And just as we can reassure a frightened woman by explaining the need for precise diagnosis, a man will be capable of overcoming his misgivings if we appeal to his reason and his sense of fairness

London, W 1 H A DAVIDSON

CHRISTMAS FACTOR IN THROMBOTEST

SIR,—There appears to be some misdirection of emphasis in Dr Nour-Eldin's letters (Nov 21 and Dec 12) on the thrombotest devised by Professor Owren[1] This new method is not designed to detect Christmas disease but to control anticoagulant therapy during which Christmas factor in addition to prothrombin and factor VII are depressed Even if the method is shown to be only a little more sensitive than existing *practical* ones the contribution of Professor Owren cannot be ignored

We have been fortunate in having had several months' experience with thrombotest. The essential reagent is sent out in lyophilised form easily reconstituted in a few minutes and the test is very simple to perform Our final assessment is nearly ready for publication.

In two cases of Christmas disease tested by us with thrombotest the clotting-times were about 10 seconds longer than normal Professor Owren, in a personal communication, has pointed out that when the test is carried out with plasma from a case of Christmas disease (concentration of Christmas factor below 1% of normal and all the other factors at 100% of normal) and then with plasma from a normal subject (concentration of all the factors at 100% of normal) the difference in clotting-times was only 6–8 seconds However, when the extrinsic clotting system is depressed during anticoagulant therapy the sensitivity to depressions in Christmas factor increases, using dilute thromboplastin reagents[2]

The thrombotest reagent appears worthy of careful clinical trial and may well prove to have a place in the routine control of anticoagulant therapy It is apparently being used extensively in Scandinavia

Anticoagulant Therapy Service,
Department of Clinical Pathology,
Manchester Royal Infirmary

H LEMPERT
L POLLER.

A CENTRAL LABORATORY FOR OCCASIONAL INVESTIGATIONS

SIR,—A number of investigations essential to the diagnosis or management of disease are demanded so rarely or are technically so inconvenient that they are not everywhere readily available They are often done as a courtesy by interested research-workers, who naturally may not undertake them always or promptly

Now that the Public Health Laboratory Service is being remoulded, the National Health Service might well establish a central laboratory able to estimate routinely follicle-stimulating hormone, urinary catecholamines, protein-bound iodine, and transaminase, to name only a few of the tests occasionally required by the general physician It would play a role in biochemical and endocrinological diagnosis as important as that of the bacteriological reference laboratories in their sphere

Obituary

HUGH DONOVAN

M B Birm , F R C S , F R C S E

Mr Hugh Donovan, senior urologist to the United Birmingham Hospitals, died on Dec 6

Born in 1897, the son of Lieut -Colonel R. T Donovan, R A M C , he was one of a family of doctors well known in the Midlands He was educated in Birmingham at King Edward's School and the university During the 1914-18 war he served in destroyers as a surgeon-probationer, and he did not qualify until 1919 He was one of Prof Seymour Barling's notable band of house-surgeons, but he did not immediately turn to surgery, for he joined the Indian Medical Service for a brief spell But once he had chosen surgery as his specialty his chief interest was always urology, and he studied this subject in London, where he was for a time a clinical assistant at St Peter's Hospital, before he was appointed assistant surgeon to the Queen's Hospital in Birmingham He remained a general surgeon with this special interest until shortly after the late war, when the death of his senior colleague, B J Ward, left him with more and more urological work Finally Donovan gave up general surgery entirely This change enabled him during the last decade to lay the foundation of a urological department, and his success was lately recognised by an invitation to become president of the British Association of Urological Surgeons in 1960, an invitation which he had to refuse because of ill health

B N B writes

" It is my misfortune to have known Hugh Donovan only during the last twelve years, for throughout these years he appeared a lonely man seeking solace in work after the early death of his wife, to whom he had been devoted But this is not to say that he was unapproachable, indeed to be *à deux* with him was to be sure of amusement and gentle understanding Despite occasional moments of contention, moments which revealed the degree of his usual self-control, gentleness pervaded his surgical life and his everyday affairs—gentleness mixed with charm and whimsy, both reminders that his Irish ancestry was stronger than his Midland upbringing Courage he had in full measure, he did not hesitate to transect the vena cava in order to transpose a ureter where lesser men would have quailed, done the reverse, and risked a ureteral stricture later He was industriousness personified, even to a fault, since it never occurred to him that his own unceasing labours necessarily involved others and might bring them to exhaustion, not that his junior staff ever complained, since his approach to any subject, conventional or otherwise, was from such an unusual slant that it would be certain to stimulate or amuse—often both Over and above there was the transparent honesty and integrity of a man tested beyond personal ambition "

DOROTHEA CLARA NASMYTH

M A Dubl , M D Lond

Dr Dorothy Nasmyth, who died on Dec 12, was something of a pioneer She was the first woman to read physiology at Oxford (and one of the few who have ever taken a first in this subject) and she was the first woman general practitioner in Oxford She qualified in 1906 and during the 1914–18 war worked in Serbia during the typhus epidemic

A M writes

" Dorothy Nasmyth's small stature, quiet voice, and slow speech hid an outstanding intellect, almost uncanny powers of perception and judgment, and a great devotion to medicine and to people But she was not ambitious She rejected the chance of an academic career because she loved general practice Her clinical judgment was remarkable and to the end of her life she often made diagnoses which seemed to be both unlikely and extraordinary, but which time or investigation proved to be correct She read widely in many branches of medicine and always made a point of learning what she could from any specialists, younger doctors, or medical students who came her way Her humble approach often gave them the impression that she was old and out of date, but her immediate understanding and her perspicacious comments soon revealed her wide knowledge of even the most modern developments Until her final illness she continued to attend lectures and clinical meetings, often driving many miles to do so

" She had many interests outside her work Perhaps the chief of these, apart from devotion to her husband and family, was a love of animals I first met her when I was ten, through the riding-school that she ran with her son and daughter The friendship, despite an age difference of some forty-five years, continued to develop until her death, for she had the ability to cross the barrier between generations She could talk as one individual to another with people of any age She seemed to retain in maturity and age the essence of childhood and youth that most people lose in passing "

DAVID ARTHUR KETCHEN CASSELLS

M D St And , M R C P E

Dr D A K Cassells, formerly chief medical officer to the alkali division of Imperial Chemical Industries, died on Dec 16 at Northwich

He was born in Fife in 1896, the son of a Scottish dominie After serving in the 1914–18 war as a combatant, he qualified from St Andrews University in 1923 He held house-appointments at Dundee Royal Infirmary and then went into general practice in Herefordshire In 1938 he took the M D at St Andrews with honours and left his practice for further study at the Postgraduate Medical School of London, taking the M R C P E in 1939

In 1940 he became medical officer to a factory where for the first time in this country tetraethyl lead was manufactured The process was full of little-known hazards, but because of his continuous vigilance there was no case of intoxication in the factory Cases, however, did occur elsewhere from time to time, and he was often called in to advise In 1946 with Sir Charles Dodds he published a classic account of tetraethyl-lead intoxication, including 25 case-histories During the late war he was appointed consulting physician to the Victoria Infirmary, Northwich, where he helped to set up a small panel of blood-donors which, until blood-banks came into being, was of great use After the war he became the first full-time chief medical officer of the alkali division of I C I He retired in 1958 Outside his work he found relaxation in bridge and fishing He leaves a widow

Notes and News

THE PREP SCHOOL

PREPARATORY schools are facing a difficult future, for in the next few years, as State schools and independent schools move closer together, more and more boys are likely to enter or leave preparatory schools at the age of 11. A short report[1] on them which has lately appeared is of exceptional interest, because it reconsiders the aims of teaching without much regard to the requirements of the public schools. At present the universities call the tune to the public schools, which in turn impose a pattern upon the preparatory schools. With greater mobility within the educational system this stranglehold will relax, and even now there are, it seems, more boys in preparatory schools than the public schools can accommodate.

The report is unusually imaginative. It argues that Latin should be taught only to those likely to be academically capable of benefiting from it, and it recommends a later start in this subject. The section devoted to the early teaching of science is especially good. Regarding such teaching as a means of "stimulating interest in natural things and of supplementing a boy's inherent interest in how things work", it goes on to outline a syllabus actually in use which appears to be unexceptionable. The need for a drive for greater literacy and fuller attention to cultural interests is emphasised. There is an admirable section on the opportunities inherent in the conception of physical education.

Parents and those interested in the generation now growing up will find this report stimulating. It is hard to avoid a sense of frustration when one realises how much could be done if there were only the money. No reference is made to the lamentable shortage of good teachers in preparatory schools today. The position is getting worse as the older ones go. Unless and until the conditions and pay attract the right men, there is small hope of these brave recommendations being fulfilled.

CLEANSING AND STERILISATION OF HOSPITAL BLANKETS

EFFORTS are being made in many hospitals to improve the hygiene of bedding and to provide each patient with freshly laundered and disinfected blankets. This is certainly desirable on æsthetic grounds, and there are apparent though unproven bacteriological advantages. But hospital authorities wishing to consider these matters must search widely for the available facts and opinions. The King Edward's Hospital Fund for London has now done this for them, and its interim report[2] contains extracts from many published papers and from replies to a questionary sent out by the Fund's division of hospital facilities. The subjects discussed include the role of unsterilised blankets in hospital cross-infection, the problems of washing and sterilising them, and the different types of blanket that are now to be had, their cost, and their acceptability to patients and nurses. On very few of these problems can a clear answer yet be given, and it is perhaps a pity that this interesting summary has been published before some of the current large-scale investigations are complete. Nevertheless, it brings together a set of references which will be useful to those who are planning trials of their own.

HOSPITALS YEAR BOOK

THE new edition of this useful and hardy annual[3] has appeared punctually and will be at hand during 1960 to offer reliable information. Besides the hospital directory there are sections giving particulars of blood-transfusion services, Government departments, statutory bodies and organisations, local health authorities, executive councils, Whitley councils, and hospital contributory and provident schemes. A substantial reference section includes indexes to statutory instruments and official circulars, legal notes, and summaries of reports, and a short bibliography of recent publications about hospital topics ranges from "accounting and finance" to "staffing". Mr J. F. Milne, the editor, in his survey of the past year soberly discusses the problems which dog all progress. He welcomes the new Mental Health Act but warns that its effect may be hindered by lack of money and staff. He welcomes work study as a necessary tool for a modern service, but points to the danger that "time and effort devoted to work study will not be matched by commensurate time and effort in applying its results".

University of Cambridge

On Dec. 12 the degree of M.CHIR. was conferred on P. P. Philip (by proxy).

University of Durham

On Dec. 19 the degrees of M.B., B.S. were conferred on the following:

Bandele Akinola Aboyade, Lilian F. C. Beattie, Kenneth Beveridge, Kenneth Bolam, T. M. Bolam, Moira M. A. Browne, W. K. Deegan, J. D. Etherington, J. G. Goundry, P. J. K. Maskery, G. W. Odling-Smee, Christine M. Peacock, F. A. Rafique, Susan J. Richardson, Mashood Babatunde Odemuyiwa (in absentia).

University of Leeds

At recent examinations the following were successful:

M.D.—John Gibson, T. K. Marshall, Ronald Spink.

M.B., Ch.B.—Helen M. Hoyle, J. M. S. Pearce, J. H. Wetherill (second-class honours), Jill E. Awcock, J. A. C. Bailey, Walter Barnes, Ann G. Benson, R. E. Blagg, A. G. Bond, Ian Cliffe, J. A. Dacre, Irene M. Dunderdale, Shirley M. Ewart, T. R. Forrest, Kenneth Fox, J. M. France, Margaret Hallas, Dharmchand Heeralall, Jennifer A. Homeshaw, R. V. Howarth, Derek Hoyle, Florence S. Hutchinson, Hamid Ikram, K. J. Kedwards, G. P. Kirkland, D. H. Mellor, Kenneth Oldroyd, B. A. Pell, Raymond Plowman, Elizabeth Rowe, Eddys E. Sherwood-Cundall, Kenneth Thornber, R. A. N. Welham, Elizabeth A. Wilford.

University of Liverpool

On Dec. 18 the following degrees and diplomas were conferred:

M.D.—Constance M. Davis, D. A. P. Evans, J. E. Riding, J. G. Warbrick.

Ch.M.—*Ranjit Basu, *Roger Brearley, John Humphreys, *P. K. Tamaskar.

M.Ch.Orth.—A. C. Da Roza (gold medal), J. A. Adams, K. V. Chaubal, A. W. B. Heywood, D. C. MacPhail, B. T. O'Connor, M. Y. Rau, M. L. Rajakaruna, *B. F. Regan, L. N. Vora.

M.B., Ch.B.—Geoffrey Balderstone, K. R. Ball, T. D. Birtles, J. A. Q. Blukoo-Allotey, Judith M. Burgess, Kenneth Cartwright, Essilt Evans, R. G. V. Hughes, B. H. E. James, J. H. Lloyd, G. W. McKenna, C. J. Merry, Patricia A. Moore, Ronald Pactor.

D.M.R.D.—P. Daranond, H. F. Davies, C. D. Krasner.

D.M.R.T.—Varunee Amaryakul.

D.T.M. & H.—D. R. Bell, G. N. Bhadresa, S. M. Bieber, R. M. Briggs, J. R. Cope, A. A. Darkwa, D. S. Gilchrist, D. R. W. Haddock, R. Harris, R. B. Hawes, M. M. Husainee, T. D. Jeyachandran, W. L. Johnson, E. D. Mahajan, G. D. E. Morris, M. A. Newland, W. I. B. Onuigbo, C. R. Rao, V. R. Rao, K. B. H. Reddy, J. H. Roach, J. T. Sorley, L. F. Tinckler, L. Tsere, Sutee Ujjin, J. T. Weir, D. G. Young.

* In absentia.

University of Manchester

At recent examinations the following were successful:

M.B., Ch.B.—G. A. Cumming, Shirley Currie, T. C. Davies, P. L. S. Dixon, D. L. Easty, Valerie K. Frazer, F. A. Hindley, F. R. Hirst, C. E. Horsfall, W. R. Hutton, M. J. Imrie, A. W. Jackson, J. H. Jones, Frank Kemble, N. P. Mallick, Shirley A. Maxwell, Doreen Millns, Rosemary G. Mitchell, K. J. Noblett, Doris E. Probert, Diana H. Seddon, Shirley E. Stanworth, J. R. Thelwell, J. B. Thomson, Margaret Ward, Sylvia A. Wood.

University of Sheffield

Dr John Knowelden has been appointed to the chair of preventive medicine and public health.

He was educated in London at King's College and St. George's Hospital. After qualifying in 1942, he served as a surgeon lieutenant in the R.N.V.R. till 1946. After demobilisation, with a Rockefeller fellowship in preventive medicine he spent a year at the Johns Hopkins School of Hygiene and Public Health, Baltimore. In 1949 he was appointed to his present post of lecturer in the department of medical statistics and epidemiology at the London School of Hygiene and Tropical Medicine. He is a member of the Medical Research Council statistical research unit, and he was secretary of the M.R.C. poliomyelitis vaccines committee which conducted the 1956 field trial of British poliomyelitis vaccine. Dr Knowelden is a joint editor of the *British Journal of Preventive Medicine*.

University of Bristol

At recent examinations for M B , CH B the following were successful

R I A A Aubee, J A G Benson, G C Duff, H W Haskins, D R M Heighton, J P A Hill, R C Hodge, G W E Lockett, Madeline D Mayne, D T H Randell, Dorothy M I Sibbald, D J Stayte, Madueke Ugwunze, Ranjit Jayakar Undugodage

University of Edinburgh

On Dec 18 the following degrees and diplomas were conferred

M D—R R Gillies, *C G I Gordon, J C Gould, R S McNeill, H W Simpson (commended for thesis), Morag S Macdonald

Ph D (*in the faculty of medicine*) —A W Williams

M B , Ch B—J W S Angus, J A Birtchnell, J B McG Fleming, J D Gilleghan, Peter Gordon, D J Harrison, J M Henderson, R G McGown, C J McKeown, J A L Mayhew, R G Moses, J E M Robertson, R T A Ross, W G Russell, Prasert Sukhum, W R Sullivan, R N T Thin, T G S Wilson

D P H—Agnes E Whitter

D M R D—A A H Brown, G M Fraser, A F MacDonald, I R Pyle

D M R T—James Frame, J F Pringle, H G Whiston

* In absentia

Queen's University of Belfast

Dr W E Glover has been appointed supernumerary lecturer in physiology

Royal College of Surgeons of Edinburgh

At a meeting of the college on Dec 18, with Prof John Bruce, the president, in the chair, A H Jacobs, P R F P S G , V C Rambo, F A C S , and J D Wade, F R C S , were admitted fellows without examination

The following were admitted to the fellowship

J B Anchen, B J Bowden, B C Bracken, Manindra Nath Brahma, D Pui-Chee Chan, Raghunath Deshika Char, G D Chisholm, E Poh Hwye Chu, E C Cowan, A C B Dean, Lakshman Chandra Dutta, Anup Mangesh Gokarn, P A Goodwin, C E Graham, E C G Lee, Brijlal-Chananram Gupta, S D Holloway, Mominul Huq, A R Isaac, G R James, Vasant Venkatrao Kayarkar, J A Kennedy, I F Kerr, K G Kling, Izak Labuschagne, W M L Laubscher, H I Leigh, P J Lethlean, J H Lowry, Abdel Wahab Reda Mabrouk, J G Mathie, Brian Measday, Mookkassan-airveettil Pullare Achutha Menon, K K Merten, W G Millar, J C Milliken, Shaikh Mohammad Monif, John Morgan, Jack Norman-Smith, T G O'Donovan, Thotathil Achuthan Paraman, Ponnampalam Paramaswnami, P R Payne, R S Phillips, Madhav Mohan Rao, W H Reid, Victor Romanowski, Subramanian Shanmugam, Inder Dev Sood, R W Springhall, James Tevendale, R N Tinning, M A Turner, Madho Prashad Vaidya, Mohomad Waliuddin, A B Young

Dr Stephen Plumpton has been elected and Dr D C Hall admitted to the fellowship in dental surgery

Society of Apothecaries of London

The following diplomas have been granted

L M S S A—R J Annison, R Cook, G A Lee G H E Woodbine, Y Y Liu, C P Juniper, G Davies, H A Gordon, J E Igwe, P R S Johnson, Z F M Newton-Nowinski, R Tiru-Chelvam

M M S A—N K Allahbadia, M H Kyi, U N Pathak

D I H—G J Clarke, R H P Fernandez, N Y Prakash, A R Prasad, S Prasad, M P Y Scott, R R L Wild

Royal Society of Medicine

William Gibson research scholarship (*£200*) —Applications for this scholarship are invited from British women doctors Further particulars may be had from the secretary of the society, 1, Wimpole Street, London, W 1 The closing date for entries is May 1

International Congress of Clinical Pathology

This conference is to be held in Madrid from June 13 to 17 There is to be a section of forensic pathology with discussions on unknown causes of death with minimum visible lesions, chemical investigations in cadaver blood, and accidents in sanguineous transfusion. Those who wish to contribute papers should write to Dr F E Camps, department of forensic medicine, London Hospital Medical College, Whitechapel, E 1, before Jan. 1

Applications for an Eli Lilly medical research fellowship ($300 a month for twelve months and travelling expenses) are invited from doctors registered in South Africa who wish to undertake research in the United States Further details can be obtained from Dr H A Shapiro, P O Box 1010, Johannesburg The closing date for applications is April 30

Twelve postgraduate travelling scholarships of £350 each are to be awarded by the British Commonwealth Nurses War Memorial Fund to nurses and midwives for study during 1960–61 Further particulars may be had from the secretary of the Fund, Dorset House, Stamford Street, London, S E 1

Central Middlesex Hospital research prizes (each of £50) have been awarded to Mr K Lloyd-Williams and Dr W H Summerskill

The British Dietetic Association (251, Brompton Road, London, S W 3) is offering a grant of £250 from the Rose Simmonds Fund for study or research in dietetics

A meeting of the Osler Club of London will be held on Thursday, Jan 14, at 8 15 P M , at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W C 1 Prof W E Kershaw and Prof P C C Garnham will speak on the history of parasitology

Semi-permanent exhibitions will be held during the winter term at the Institute of Dermatology, Lisle Street, London, W C 2 The first, from Jan 4 to 27, will be by Dr William Frain-Bell on drug eruptions

The Ministry of Power has published its digest of statistics of pneumoconiosis in the mining and quarrying industries for 1958 Copies may be had from H M Stationery Office (3*s* 6*d*)

A revised British Standard for rubber-proofed bed sheeting for hospital use has been published (B S 2508 1959) Copies (price 4*s*) may be obtained from the British Standards Institution, Sales Branch, 2, Park Street, London, W 1

Appointments

de Souza, W D , M B Bombay orthopædic registrar, Peterborough group of hospitals

Hogarth, T B , M B Leeds, F R C S E part-time consultant in otolaryngology, Scarborough, Bridlington, and Whitby area hospitals

Kerr, W F , M B W'srand, F R C S E senior registrar in thoracic surgery, Papworth Hospital, Cambridge

Lagowski, Anatol, M D Lwow, D A assistant anæsthetist (S H M O), Scarborough, Bridlington, Malton, and Whitby group of hospitals

Leonard, B J , M D Manc consultant pathologist, Derby group of hospitals

Paley, R G , M D , PH D Leeds, M R C P E consultant physician (with special interest in geriatrics), South East Northumberland, Wansbeck, Alnwick and Rathbury, and Berwick upon Tweed groups of hospitals

Somner, A R , M D Edin , M R C P E consultant chest physician, South East Northumberland and Newcastle upon Tyne groups of hospitals

The Hospital for Sick Children, Great Ormond Street, London

Bruce, A W , M B Aberd , F R C S E surgical outpatient assistant

Evans, Rachel G , M B Lond house-physician

Inall, J A , M B Sydney, D C H house-physician

Simpkiss, M J , M B Birm , M R C P resident assistant physician

Talwalker, V C , M B Bombay house-surgeon

South-Eastern Regional Hospital Board, Scotland

Conacher, W D H , M B Glasg , M R C P E consultant physician, West Lothian group hospitals

Horton, Jean M , M B Lond , F F A R C S , D A consultant anæsthetist, department of surgical neurology, Western General Hospital, Edinburgh, and Edinburgh Royal Infirmary

Laidlaw, John, M B Edin , M R C P E clinical neurophysiologist (S H M O), department of surgical neurology, Edinburgh

Petrie, P W R , O B E , M B Edin , D T M & H , D P H assistant S A.M O to the Board

Smith, A W M , M B Edin , M R.C P E consultant physician, Fife area hospitals

Welsh Regional Hospital Board

Davies, T S , M R C S , D P M consultant in mental deficiency and medical superintendent, Llanfrechfa Grange, near Cwnbran

Leitch, G B , M B Dubl , F R C S E , D L O consultant E N T surgeon based at Royal Gwent Hospital, Newport

Packer, R E , M B , B SC Wales, D O M S consultant ophthalmologist, Glantawe H M C area

Thomas, T J , M R C S , D M R D consultant radiologist, Merthyr and Aberdare H M C

Colonial Appointments

Blenkinsopp E M , M R C S district M O , St Vincent

Dawson, I E , M B Glasg medical superintendent, Zanzibar

Fisher, P W , M B Cantab M O , South Pacific health service

Goulding, M D , M B Madras, D T M & H registrar, health department, Trinidad

Guy, W D , M B Glasg M O , Northern Region, Nigeria

Hurley, D W H , M B N U I , F R C.S surgeon specialist, Zanzibar

Births, Marriages, Deaths

DEATHS

Turnbull —On Dec 23, after a short illness Dr Peter Mortimer Turnbull M C , M B , of 63, Woodbourne Avenue, Streatham, S W 16, late medical superintendent of Tooting Bec Hospital, aged 80

A PLACE FOR HISTAMINE IN NORMAL PHYSIOLOGY *

GEORG KAHLSON
M.D. Munich and Lund, Hon. M.D. Oslo
PROFESSOR OF PHYSIOLOGY, UNIVERSITY OF LUND, SWEDEN

UNTIL very recently studies on histamine were mainly concerned with its distribution, liberation, origin, and mode of binding. This " static " approach to the problem, imposed by limitations in available methods, has led to the present impasse in the interpretation of the physiological significance of histamine. A more dynamic approach would place less emphasis on the content than on the rate of formation, the rapidity of turnover, or the rate of " usage " of the amine. In Lund our interest was first turned in this direction by the observation that cats could be starved to the extreme without any concomitant change in the content and distribution of histamine (Haeger and Kahlson 1952). Even removal of the pituitary gland or adrenals did not cause such changes (Haeger, Jacobsohn, and Kahlson 1952). Complete inhibition of the histamine-destroying enzyme histaminase did not influence the tissue content of histamine (Kahlson, Rosengren, and Westling 1958a). We further found evidence of a kind of regulatory mechanism designed to keep constant the tissue level of histamine in the gastro-intestinal tract (Haeger, Kahlson, and Westling 1953). All this suggested that the actual tissue content of histamine is a poor indicator of changes in the metabolism of the amine. Consequently we decided to study the spontaneous liberation and rate of formation of histamine under various physiological conditions.

The Origin of Histamine

No methods are available for the accurate estimation of the small changes in the histamine level of blood or plasma which might possibly occur in physiological conditions.

Gaddum (1951) and his colleagues suggested that estimation of histamine in the urine is more likely to give information about the release of histamine in the body than investigations on blood. But this approach is limited by the fact that the food commonly eaten by man and laboratory animals contains substantial amounts of histamine, part of which is excreted in the urine. Further, with such a diet intestinal bacteria decarboxylate histidine to histamine, so adding more exogenous histamine. Large amounts of urinary histamine derived from exogenous sources are likely to conceal increases in urinary histamine derived from increased production or spontaneous release of endogenous histamine.

The complications due to exogenous histamine can be overcome. With two colleagues (Gustafsson, Kahlson, and Rosengren 1957) I investigated the distribution and urinary excretion in germ-free-reared rats fed on a special histamine-free diet, and compared these results with those from ordinary rats fed on the same diet. The distribution and urinary excretion of histamine were largely identical in the two groups of rats, indicating that, when the histamine-free diet is given, the histamine excreted and contained in the tissues is endogenous in origin both in germ-free and normal animals. In the male rat urinary histamine is mainly in the conjugated form. In the female rat, fortunately, the urinary histamine is almost exclusively in the free, biologically active form, which allows assay directly on the isolated ileum of the guineapig. The urinary excretion in what I shall call our " standard rat " thus provides a useful baseline for our studies, and I shall show by further experiments that in this rat the urinary excretion of histamine runs parallel with the rate of formation.

Inhibition of Histamine Formation in Vivo

Until recently no means were known for measuring in vivo the rate of histamine formation. Studies of the urinary histamine in the female rat, measured by the isotopic methods devised by Schayer (1959) have so far proved most useful. (Indeed Schayer's work has contributed decisively to a new era in histamine research.) The isotopic method depends principally on the injection of ^{14}C-histidine and measurement of ^{14}C-histamine and its metabolites excreted in the urine. In the female rat diamine oxidase (histaminase) is the main histamine-destroying enzyme, and aminoguanidine is its specific inhibitor. Under the influence of aminoguanidine a larger proportion of the histamine formed will be excreted in the urine.

Histidine decarboxylase, the enzyme which converts histidine to histamine, can be inhibited in vitro by semicarbazide, but this inhibition is neither very strong nor specific. Miss Rosengren and I have injected our standard rat with semicarbazide in gradually increasing doses, and studied the urinary histamine output over periods of days or weeks. For the first day or two the urinary histamine is lowered, and then, despite the sustained influence of the inhibitor, the original histamine output is restored. When the injections are discontinued, however, the urinary histamine rises far above normal values, suggesting that the enzyme inhibition is overridden by the simultaneous formation of new molecules of histidine decarboxylase. We were able to overcome this " escape " from the influence of the inhibitor by feeding the standard rat on a diet deficient in pyridoxine, a coenzyme of histidine decarboxylase. On this diet semicarbazide in gradually increasing doses reduces the histamine formation to as little as 20% of normal (fig. 1), the animal appeared fairly fit as regards appetite, exercise, and maintenance of body-weight. When semicarbazide is discontinued the striking increase in urinary histamine reflects the overshoot in histamine formation. The histamine content of the skin of the back, abdomen, and ears was examined before and at the time of greatest inhibition of histamine formation. The two sets of figures did not differ, and they show the lack of correlation between content and rate of formation in the skin. This inconsistency can be accounted for by assuming that all binding sites are occupied and that the histamine molecules are held there even when histamine is formed at a very low rate. If this is true, then even a strong histamine inhibitor is unlikely to counteract the adverse effects of histamine liberated in anaphylaxis or allergy. Measures aimed at hindering or tightening the coupling of histamine to the binding sites seems a priori, more promising as a remedial approach. Cortisone seems to hinder the coupling of histamine to the binding sites (Schayer 1956).

---

* A lecture (abbreviated) delivered in the department of pharmacology of Oxford University, in May, 1959, and at the University of Liverpool, in November, 1959.

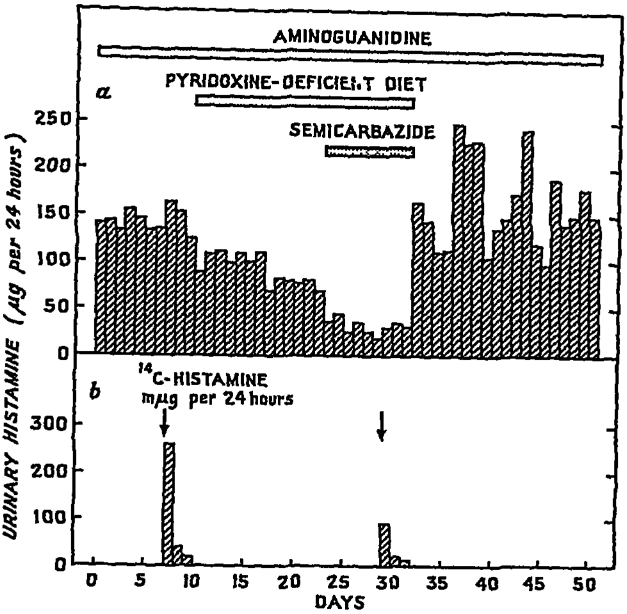

Fig 1—Female rat fed on a specially compounded histamine-free diet (a) Urinary excretion of free histamine (b) Excretion of ^{14}C-histamine in 0 001 μg (mμg) after subcutaneous injection of 220 μg ^{14}C-histidine (1 mg per kg)

Throughout the experiment the rat was under the influence of the histaminase inhibitor aminoguanidine Pyridoxine was omitted from the diet from the 10th to 32nd day Semicarbazide was injected subcutaneously on the 23rd to 32nd days (1st day 50 mg per kg twice daily, and 2nd day onwards 75 mg per kg twice daily)

Antihistamines do not affect the binding sites for histamine, which are different entities from the receptors through which the effects of liberated histamine on smooth muscle and glands are elicited

Histamine in Pregnancy

Increased Formation of Histamine

The basic observations on histamine formation in pregnancy are represented in fig 2 In the rat abundant production of histamine starts on the 15th day of pregnancy, as indicated by the rise in urinary excretion A peak is reached about a day before term, and then, within about 24 hours, the formation of histamine subsides to the prepregnancy level (Kahlson et al 1958a) If the fœtuses are removed surgically, without interfering with the other products of pregnancy, the rapid histamine formation promptly ceases (Kahlson, Rosengren, Westling, and White 1958b)

To establish which fœtal tissue is responsible for histamine formation, and to assess the rate of production, we incubated various tissues in vitro with radioactive histidine, and measured the ^{14}C-histamine formed The table shows that the liver produces histamine at an enormously high rate The histamine-forming capacity per gramme of tissue is about a hundred times higher in the liver than in most other tissues Even the stomach wall, which in the adult rat is the most potent manufacturer of histamine, is considerably less active per unit weight than the fœtal liver, and a mast-cell tumour of a dog, investigated in our laboratory (Lindell et al 1959), was about a hundred times less active in forming histamine In the fœtus about 80% of the total histamine formation takes place in the liver The day before term the urinary excretion of histamine falls, and within a short time—i e, 2-3 days—the histidine-decarboxylase activity of the liver regresses from an unparalleled height to the low level found in the newborn and adult animal (see table) (Kahlson, Rosengren, and White 1959)

Absence of Mast Cells and Type of Binding

Mast cells were not found in the fœtal tissues examined except for the skin

In adult animal tissues, histamine is not easily extracted unless drastic procedures which destroy cell structures are used In the fœtus the situation is entirely different The histamine so abundantly formed diffuses freely into the surrounding fluid When fœtal-tissue suspensions were incubated with ^{14}C-histidine and centrifuged, about 85% of the ^{14}C-histamine formed was in the supernatant fluid Fœtal tissues bind histamine only loosely, contain little, and produce it at a high rate, hence they are subjected to histamine in a state of rapid turnover (Kahlson et al 1959)

Histamine Formation in the Human Fœtus

We have investigated the fœtal histamine formation in man and found evidence that it is considerable (Kahlson et al 1959) Our knowledge of the mechanism is not yet as complete in man as it is in the rat In human pregnancies terminated on psychiatric grounds, we investigated the histamine content of the maternal and fœtal blood With the fœtus (weight 90-285 g) in utero at cæsarean section blood was collected from an umbilical artery The fœtus was then removed and blood was withdrawn from a carotid artery Blood was also collected from the umbilical vessels of healthy women at term Whereas fœtal carotid-artery and umbilical-artery plasma contained histamine in measurable amounts, the maternal plasma did not The umbilical-vein plasma contained less, and this difference is likely to result from diffusion between fœtal and maternal blood in the placenta

The Status of Histaminase

The striking increase in histaminolytic activity that can be shown in vitro in plasma from pregnant women is the first and only generally accepted record of a major change in histamine metabolism in normal physiology

The role of blood histaminase in pregnancy, always obscure, has become even more so on closer examination Some years

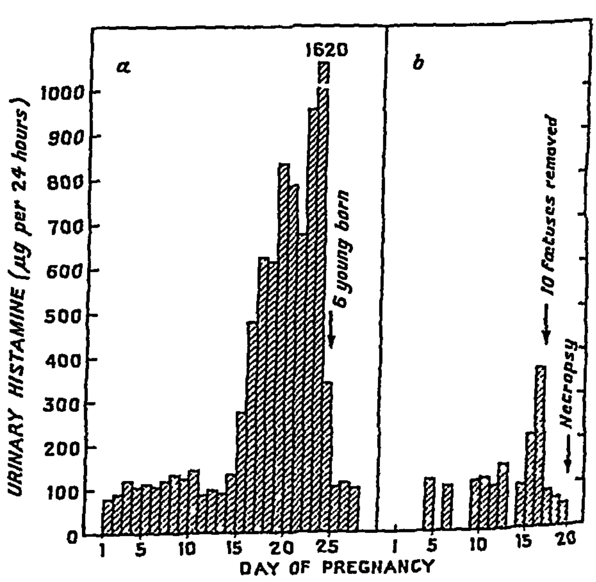

Fig 2—Urinary excretion of histamine (a) in a normal pregnant rat and (b) in a rat from which the fœtuses were removed at the 17th day of gestation

Aminoguanidine was given throughout (From Kahlson et al [1958b], by permission of the editorial board of the *Journal of Physiology*)

THE RATE OF IN-VITRO HISTAMINE FORMATION BY VARIOUS ORGANS OF RAT FŒTUSES (AT THE 19TH AND 21ST DAY OF GESTATION), NEWBORN (WITHIN 3 HOURS OF BIRTH), 2-DAY-OLD YOUNG, AND ADULTS

Tissue	19-day litter	21-day litter	Newborn	Young	Pregnant adult
Total body		340	76–970	15	
Liver	14,000 *(23,000)*	2280		5–40	5
Lungs	1900	150		5	90–150
Heart		140		0	
Kidneys		190		0	<5
Gastrointestinal tract		150			
Brain	10	20		0	
"Rest of the body" (muscle, skin, bone)	130 *(220)*	70		30	
Stomach	2800				370–980

The figures represent ^{14}C-histamine formed in 3 hours from ^{14}C-*l*-histidine expressed as counts per min. per g of tissue. 1 µg ^{14}C-histamine gives 600 counts per min. The results for the organs were obtained by pooling the tissues in each litter The figures in parentheses are the mean determinations in three litters. The other figures in the first column are from the same litter

ago Carlsten and Wood (1951) noticed in cats that transfer of large amounts of histaminase from the kidneys and intestinal mucosa via the lymphatics into the blood-stream, as a result of adrenalectomy, did not cause a measurable increase in blood-histaminase activity The active enzyme disappeared rapidly from the blood

Lindell et al (1958) have reinvestigated, by isotopic methods, the problem of histaminase in human pregnancy They studied in vivo the metabolism of injected ^{14}C-histamine in pregnant and non-pregnant women. The urinary pattern of the various metabolic products of injected ^{14}C-histamine showed no evidence that histaminase took a substantially greater part in the metabolism of histamine in pregnant than in non-pregnant women. That is to say that the high in-vitro histaminase activity of the placenta and blood-plasma in pregnancy does not contribute in vivo to the inactivation of injected histamine. This finding explains why there is no difference in the sensitivity of pregnant and non-pregnant women to injected histamine judged by the magnitude of the responses so far studied. It should not be taken to indicate that the strong histaminolytic activity in various tissues in vitro represents biochemical or experimental artefacts For example, it has been shown repeatedly that in our standard rat the urinary excretion of histamine increases two or three times under the influence of the histaminase inhibitor aminoguanidine The whole problem of histaminase is complex. Studies on histaminase have so far contributed little if anything to our understanding of the physiological significance of histamine, in contrast to what we have learnt from the effect of cholinesterase on acetylcholine.

Resistance in Pregnancy to Histamine-induced Gastric Ulcer

During pregnancy rats are exposed to histamine to an extent which in the non-pregnant animal induces gastric ulcers An average litter of rat fœtuses produces, towards the end of pregnancy, more histamine in 24 hours than is present in the mother rat. About 2–6 mg of fœtal histamine enters the maternal rat circulation in 24 hours A mere fraction of this amount, when mobilised from the non-pregnant animal's own stores by the injection of a histamine liberator, causes ulceration of the glandular part of the stomach (Franco-Browder et al 1959) Injections of long-acting histamine in beeswax produced ulcers in the stomach and duodenal mucosa in the eight species studied by Hay et al (1942) Thus pregnancy seems to protect the stomach against histamine-induced ulceration Clinical colleagues tell me that peptic ulcers are rarely seen and that manifest ulcers tend to heal in pregnant women The pregnant rat seems to be ideal for studying the way in which the stomach is protected from ulceration (Incidentally the strong claim for histamine as the final link in the physiological chain of events stimulating acid gastric secretion should be mentioned Gastrin appears to liberate histamine [Emmelin and Kahlson 1944, Kahlson 1948, Smith 1954] ^{14}C-histamine, deposited after injection of ^{14}C-histidine, is released in the rat's stomach on feeding [Schayer and Ivy 1957, 1958]) Here we are concerned with non-mast-cell histamine, since these cells are few or absent in the glandular gastric mucosa (Riley and West 1956)

Speculations on the Significance of Increased Histamine Formation

One can do little more than guess the meaning of the rapid histamine formation observed in pregnancy If we knew of major changes in the rat fœtus at the 15th day of gestation and the day before term (the days of onset and decline of the changes in the histamine-forming capacity) this would give a clue. The smooth muscle of the uterus, which is subjected to mechanical stimulation by distension during the period of rapid growth of the fœtuses, does not contract before term The uterine muscle seems to be inhibited in some way, and such inhibition may originate from fœtal histamine This period coincides largely with that of increased histamine formation. In the rat histamine inhibits the smooth muscle of the uterus and may well provide the requisite block Even the cessation of histamine formation before parturition appears to be appropriately timed This view is being tested by finding to what extent long-acting histamine in beeswax deposited under the skin postpones parturition

In no other species so far investigated does histamine inhibit uterine motility In these species the function of fœtal histamine formation must be different from that in the rat My colleagues and I thought that histamine formation in the fœtus might somehow be related to the general process of growth, and this idea can be examined.

Histamine and Growth

Histamine Formation in the Regenerating Liver

The growth of the regenerating liver is particularly relevant to our study, because, like fœtal growth, its rate is very rapid In the rat the median and left lateral lobes of the liver, amounting to about two-thirds in weight, can be removed This operation has little obvious effect on the rat. The remnant grows and reaches the size of the normal liver within 20 days The rate of growth is particularly rapid during the first few days after operation (see Harkness 1957)

In partially hepatectomised rats Miss Rosengren and I found that the rate of histamine formation is considerably increased during the phase of liver regeneration The rate of formation is particularly high during the first week when the growth is rapid. When radioactive histidine was injected, so that histamine was formed, decarboxylation took place faster during liver regeneration than before operation The rate of histamine formation subsided when the regenerative growth was completed. We found no mast cells in the regenerating liver tissues

Histamine Formation and Wound Healing

The results on the liver encouraged us to explore the possible involvement of histamine in a third type of growth—namely, wound healing At our institute a method has been devised by which the tensile strength of healing wounds can be measured Working with Dr B Zederfeldt on rats, we found that repeated injections of the histamine liberator 48/80 considerably increased the tensile strength of healing skin incisions Since Schayer et al (1959) demonstrated that 48/80, with the mobilisation of histamine, causes a great increase in the histidine-decarboxylase activity of rat skin, we have recognised that the augmented tensile strength of the wound may be linked with an accelerated formation of histamine We have also made measurements in rats in which histamine formation was inhibited by the combination of a pyridoxine-deficient diet and semicarbazide In these experiments the tensile strength of healing skin incisions was greatly reduced In the few experiments we have made so far at the time of "overshoot" in the rate of histamine formation after a period of inhibition, the tensile strength has been considerably increased The connection between histamine formation and constructive metabolism in healing wounds is so close as to be reciprocal At some later stage of knowledge this relation may be useful in medical practice

Enzyme Inhibition and Fœtal Development

The chain of evidence associating histamine-forming capacity with the general processes of growth and repair would be complete if one could show that these processes were impaired as a consequence of inhibition of histamine formation As I stated earlier, no specific inhibitors of histidine decarboxylase are available as yet But the combination of the inhibitory effects on this enzyme of pyridoxine deficiency and semicarbazide will reduce the rate of histamine formation to a very low level Miss Rosengren and I have investigated the effect of this type of enzyme inhibition on fœtal development in the rat

In one group of rats fed on a pyridoxine-deficient diet, semicarbazide was given for 8 days from the 7th day of pregnancy—that is at about the time of implantation of the ovum. On examining the uterine contents at the 19th day (when the weight of a normal fœtus is about 2 g), the fœtuses were dead, being reduced to a tiny mass of disintegrated material, and the placentæ were small and in a state of regression

In a second group of rats, also fed on a pyridoxine-deficient diet, semicarbazide was given for 8 days from the 15th day of pregnancy When the animals were killed on the 22nd day the findings were much the same as in the first group, the fœtuses were dead and mummified, and their growth seemed to have been arrested at about the 17th day—i e , when enzyme inhibition was greatest Supporting evidence has been obtained in another group of rats in which injections of the inhibitor were started at the 17th day

In controls fed on the deficient diet or injected with semicarbazide only no abnormalities in the course of pregnancy and fœtal development were noted (Kahlson and Rosengren 1959)

Thus, after reaching a more advanced stage of development, at about the day before term, fœtal growth seems to depend no longer on a high histamine-forming capacity As shown in fig 2 and the table, histamine formation regresses at about 24 hours before term to the non-pregnant level Accordingly we have found that living young of normal weight are born when enzyme inhibition is instituted during the last days of pregnancy

Semicarbazide, which is recognised as a carbonyl reacting agent, is known to inhibit a wide variety of enzymes, such as various aminoacid decarboxylases and amine oxidases, among them histaminase None of the agents whose formation is known to be inhibited by semicarbazide, has so far been found to be specifically related to fœtal development We have found that complete inhibition of diamine oxidase by aminoguanidine has no effect on the course of pregnancy or the fitness of the newborn (Kahlson et al 1958a) Further, Dr G B West and Dr H Westling have shown that the formation of 5-hydroxytryptamine is not increased in the rat during pregnancy Lastly, semicarbazide in doses larger than were used in our experiments did not inhibit the endogenous formation of 5-hydroxytryptamine in the guineapig (Weissbach et al 1957) Thus it seems reasonable to assume that the inhibition of fœtal development caused by semicarbazide is due to inhibition of histidine decarboxylase as shown by the measurable decrease in urinary histamine Final proof of this assumption will have to await the finding of specific non-toxic inhibitors of histidine decarboxylase The discovery of a rich source of the enzyme—the fœtal rat liver—is likely to boost the search for a specific inhibitor

Histamine Metabolism of the Brain

Prof Geoffrey Harris, Dr Dora Jacobsohn, and I (1952) showed that the parts of the brain functionally related to the anterior-pituitary gland, the hypothalamus, and the median eminence contained large amounts of histamine, whereas other parts of the brain examined contained very little My colleague Dr White (1959), who has now studied in vitro the formation and catabolism of histamine in brain tissue, using Schayer's isotope-dilution technique, finds that the hypothalamus forms histamine much faster than other parts of the brain

Our findings in 1952 induced Miss Fuche and me to investigate the effect of small "physiological" quantities of histamine on the secretory activity of the anterior-pituitary gland You will recall that Harris and Jacobsohn (1952), in classical experiments, showed that the anterior-pituitary gland depends for its proper function not on nervous but on vascular connections with those regions in which we found histamine in abundance Miss Fuche and I (1957) noted in rabbits in which the adrenal medulla had been destroyed that the intravenous infusion of as little as 50 µg per kg of histamine caused a significant lymphopenic response which in time, course, and pattern was identical with the response to injected corticotrophin This response to histamine was absent after hypophysectomy As a result of this work histamine is included among the possible chemical mediators of the cerebral control of the anterior-pituitary gland In exploring the physiological functions of histamine we again encounter non-mast-cell histamine The brain has no mast cells (Riley 1959)

Histamine in Muscular Exercise and Hypoxia

When histamine was brought on the physiological scene, it was thought to be responsible for the vasodilatation of contracting skeletal muscle and for the phenomenon of reactive hyperæmia Thomas Lewis cautiously introduced the term "H-substance" for this agent But Anrep, who contributed brilliantly to knowledge in this field by his studies on the nature of urinary histamine (in which he measured the arteriovenous histamine difference in muscles at work and skin in oxygen-lack), claimed identity of the hypothetical H-substance with histamine After histamine had thus been brought into the limelight, many investigators set out to assess its role in reactive vasodilatation Much was written on the subject from many parts of the world In Lund we have worked hard in this field, and I was privileged to study the problem in Cairo under the guidance of the late Professor Anrep But, despite all this effort, the consensus of current opinion is that histamine has not with certainty been shown to play a part in any of the various kinds of reactive hyperæmia so far investigated

Oxygen-lack is well known to affect the small blood-vessels directly, dilating them as in reactive hyperæmia, and so it seemed appropriate to examine the output of histamine in this condition In experiments made in collaboration with Miss Rosengren, our standard rats were exposed to hypoxia in the low-pressure chamber of our subdivision of Aviation Physiology The chamber was evacuated to a pressure of about 6000 m, with an oxygen content of 45% of that at sea-level In the chamber the rats showed signs of oxygen-lack Urine was collected in 24-hour periods Under the influence of hypoxia the rate of histamine formation was reduced to roughly half of normal If mobilisation of histamine were concerned in the reactive hyperæmia of oxygen-lack, the reverse should have happened. The experiments so far made are only preliminary and merely show that histamine is in some way involved We plan to study in greater detail the nature of the underlying changes in histamine metabolism

Concluding Remarks

To those, like myself, who have been trying to find a simple and clear cause-and-effect relation in which histamine acts as a direct stimulus to and controller of effector cells (such as smooth muscle, blood-vessels, and glands) the present findings may seem bewildering It now appears, however, that the histamine-forming capacity is in some way connected with the metabolic machinery common to the anabolic processes of development, growth, and repair The situation is complex and we cannot yet say whether the observed changes in the rate of histamine formation are essential to the events studied or whether they are the outcome of a different primary physiological reaction In exploring the role of histamine in normal physiology, further work on the inhibition of histamine formation and its consequences in the animal seems particularly promising, especially in relation to fœtal development.

Through the veil two facts emerge with considerable certainty

1 Histamine, as linked with the physiological events at present being studied, is not formed from mast cells

2 As far as physiology is concerned, studies of the rate of histamine formation are more promising than the measurement of histamine content.

CONTROL OF LIPÆMIA IN CHILDREN WITH DIABETES MELLITUS

THE ROLE OF INSULIN AND THE EFFECTS OF A DIET RICH IN UNSATURATED FATTY ACIDS

From the University Department of Pædiatrics and Child Health and the Children's Hospital, Birmingham

In an earlier publication (Wolff and Salt 1958) it was noted that initially high levels of β-lipoprotein lipid in the serum of untreated diabetic children were rapidly lowered by treatment with insulin Moreover, in a group of children under good or fair diabetic control, the mean levels of β-lipoprotein lipid, cholesterol, and esterified fatty acid in the serum were higher in patients with blood-sugar levels above 200 mg per 100 ml than in those with levels below 200 mg It was suggested that high levels of certain serum lipids might be at least partly responsible for the early onset of vascular complications in the young diabetic

In the present study we have attempted to define the effects of insulin on the various serum lipids Further, in a number of patients already under insulin control, we have studied the diurnal variation of serum lipids to determine how closely blood-sugar and the lipids are related

In practice, one cannot expect that blood-sugar control will be maintained through the years strictly enough to keep the serum lipids always at a minimum For this reason we have investigated, in these diabetic children, the effects of a diet rich in unsaturated fatty acid esters

In a preliminary experiment an emulsion of sunflower-seed oil was given in substitution for some of the animal fat of the ordinary diets Later, more success was obtained with foodstuffs whose fat was largely composed of corn (maize) oil. When these were given in strict isocaloric exchange with animal fat of the usual diet, certain serum-lipid concentrations were lowered to levels not attainable with insulin alone, and these low levels were maintained even when insulin therapy was somewhat relaxed

In view of the possible causal relation between elevation of the serum lipids and the early onset of vascular complications in the diabetic patient, these findings may have practical importance

The Investigation

Our fourteen patients were between the ages of 2 and 14, with diabetes mellitus of varying duration Four of them, hitherto untreated, were studied to reveal changes in the serum lipids when insulin treatment was first begun In four already under insulin control diurnal variation of the serum lipids was studied Eight under insulin control were fed sunflower-seed oil emulsion, five other patients were given a diet containing corn oil

In preliminary experiments, the usual dietary fat was reduced and a 50% emulsion of sunflower-seed oil in water, suitably flavoured, was given thrice daily The daily

TABLE I—BLOOD-SUGAR AND SERUM-LIPID LEVELS IN FOUR PREVIOUSLY UNTREATED PATIENTS DURING THE FIRST PHASE OF INSULIN THERAPY

Patient	Hours after insulin therapy begun	Blood-sugar (mg per 100 ml)	Serum lipid (mg per 100 ml)										Total lipid

amount of 50 g oil contained about 30 g linoleic acid as the main unsaturated (dienoic) fatty acid

In later experiments, the diets contained special milk, margarine, and cheese-spread, all made with corn (maize) oil instead of animal fat Corn oil contains about half its weight of linoleic acid as the main unsaturated fatty acid The diets were arranged to contain 50 g corn oil per day for the older children and 40 g for the younger, as well as known amounts of protein (40 to 60 g) and carbohydrate (170 to 230 g) graded according to age The quantities of corn oil, together with 15 g other dietary (animal) fat, replaced the total animal fat included in the control diets given before and after the periods of corn-oil feeding The protein and carbohydrate contents of the corn-oil and control diets were kept constant for each patient throughout the experiments

In three patients fat-balance studies for periods of 3 days showed normal fat absorption on the corn-oil diet

Blood-sugar was estimated by the Folin-Wu micro-technique, using unlaked blood in Herbert and Bourne's method (Harrison 1937)

Serum lipoprotein was separated electrophoretically on absorbent paper into ω, β, and α fractions, after staining with oil red O these fractions were estimated on a relative basis by the method described by Salt and Wolff (1957) The fractions were calculated as absolute concentrations by reference to the serum total-lipid concentrations determined by the method of de la Huerga et al (1953)

Analyses of sera for esterified cholesterol and unesterified cholesterol (Schoenheimer and Sperry 1934), lipid phosphorus (method adapted from Gomori 1942) and total esterified fatty acid (Stern and Shapiro 1953) were also made

In calculations, a representative molecular weight of 277 2 was used for fatty acid, phospholipid (M W 806) was obtained by lipid phosphorus ×26, triglyceride was computed by difference calculation

Results

Effects of Insulin on Hyperlipæmia

Table I shows the effects of insulin on the serum lipids and lipoproteins in four previously untreated patients They were all conscious on admission, patient A was drowsy and she was the only one who was dehydrated Ketonuria was present in patients A, B, and D

Under insulin the high values for serum total-lipid, esterified fatty acid, triglyceride, phospholipid, and β-lipoprotein lipid were lowered to normal within 24 or 48 hours The α-lipoprotein lipid fraction showed little change, raised β/α ratios decreased rapidly No uniform change occurred in the serum-cholesterol levels In three cases these were already normal, in patient B, in whom the concentration was initially high, it was brought down to normal In patients B and D the initially high ω-fraction became normal

In patient A the β-lipoprotein was very high at first but the ω fraction was not raised and the serum was optically clear As the serum-cholesterol and phospholipid values were normal but the triglyceride markedly raised, we conclude that the high β fraction resulted from accumulation within it of triglyceride In patient C the findings were similar, though the hyperlipæmia was less In patient D the excess triglyceride was largely in the form of chylomicrons (ω fraction), and the serum was turbid

The observations suggest that, in these untreated diabetic children, an initial excess of triglyceride was usually and mainly responsible for the hyperlipæmia, and was present either in the β-lipoprotein complex or in the form of chylomicrons (ω fraction) Insulin treatment rapidly lowered the raised triglyceride levels irrespective of whether the excess was in the ω- or β-lipoprotein fractions

Diurnal Variations in Serum Lipids

We next tried to determine whether there was any relation between blood-sugar levels and any of the serum lipids during a 24-hour period in patients in whom diabetic control had already been established

Blood specimens were so timed as to avoid postprandial elevations of serum triglyceride In one patient, blood-sugar and the various serum lipids were estimated at 4 separate times, spaced at intervals between 7 A M and midnight, on 4 different days The widest variation in diurnal blood-sugar observed was from 52 to 384 mg per 100 ml On this day, as on the other occasions, the diurnal variation in all the lipid fractions was trivial In this patient on a later occasion, and in three other patients, comparable observations of blood-sugar and serum-lipid concentrations were made just before and 3 hours after the midday meal

The results confirmed the diurnal constancy of the lipid levels

Effects of Unsaturated Fats

Sunflower-seed oil—The effects of this oil on serum-lipid concentrations were studied in eight diabetic children already under established control with insulin The first trial extended over 28 days while the patient was in hospital and the unsaturated dietary fat was given in place of an equal amount of the usual (largely animal) dietary fat Initially the serum lipids were all within the normal range The effect of the oil feeding, observed at 14 days, was a lowering of the serum esterified-cholesterol and β-lipoprotein-lipid concentrations At 28 days the lower levels were maintained

This patient on a later occasion, and seven others, were fed sunflower-seed oil at home for periods of 22 to 42 days Under home conditions there was some uncertainty about the maintenance of the diet, and in some patients the insulin dosage had to be increased a little during the trial These factors may have led to less clear results However, the serum β-lipoprotein lipid fell in every patient, and the esterified cholesterol fell in most of those whose initial levels were not already low On a mean basis, serum β-lipoprotein, esterified fatty acid, and phospholipid were lowered to about 80% of the initial levels, esterified cholesterol to about 90%, and triglyceride to about 60% When sunflower-seed oil feeding was discontinued, all these lipids reverted to previous levels

Corn oil —Table II shows the effects of the corn-oil diet on the serum lipids in five patients

The blood specimens were taken at noon, before the midday meal, so that alimentary lipæmia would not complicate the findings The ranges and mean values for the serum-lipid concentrations are given only for periods when steady levels had been achieved with the different diets Analytical values were also recorded for the transition periods but are excluded from the calculations

In patients B and D the diagnosis had been made recently, and the rapid changes induced by insulin therapy have already been described In patient E the disease was also of short duration In all three cases the corn-oil diet was started only after the initial hyperlipæmia had responded to insulin and the various serum lipids had reached steady levels for 1–3 weeks

Patient F, in whom the diagnosis had been made 2 years previously, was also given the corn-oil diet In his case evaluation of the data was complicated, because diabetic control was being improved by an increase in insulin dosage during the first control period and shortly before the change to the corn-oil diet The increased insulin control caused a progressive fall of the blood-sugar, serum-phospholipid, triglyceride, and β-lipoprotein-lipid levels

Patient G was newly diagnosed and was fed the corn-oil diet from the beginning of insulin therapy, consequently there was no initial control diet period The values recorded for the corn-oil period (table II) were obtained only when insulin control had become established

The corn-oil diet reduced esterified cholesterol and β-lipoprotein lipid to about 60% of the initial control levels, total-lipid and esterified fatty acid to about 75%, unesterified cholesterol and phospholipid to about 80% The α fraction was lowered to about 90% and the β/α ratio to about 65% of the control levels Serum triglyceride and the ω fraction showed no consistent change

Two of the patients are being maintained on the corn-oil diet and the results will be reported

In three patients (E, F, and G) the diet was changed again from corn oil to control The effects of the isocaloric change are shown in table II As was expected, a marked rise occurred in all the serum-lipid levels which had been lowered by the corn-oil diet, though at the end of 3 weeks some fractions had not fully regained the levels characteristic of the initial control period

The detailed effects of the corn-oil diet are shown for patient B in fig 1 α-lipoprotein lipid increased during the transition period while other serum-lipid levels were falling Later, when the new equilibrium levels were reached, the α fraction had fallen and reverted to the control level In patient D similar changes were observed

Insulin and Corn Oil

In two patients we tried to find out whether the corn oil could prevent the rise of certain serum lipids which is to be expected when diabetic control is allowed to deteriorate

Fig 2 shows the results for patient E, in whom insulin dosage was approximately halved for a time Despite the corn-oil diet, when blood-sugar was elevated there was a definite rise in serum triglyceride, esterified fatty acid, and ω fraction, a slight rise in the β fraction, and a fall in the α fraction These changes are in the opposite direction to those already described in the previously untreated patient when started on insulin therapy and they were in the same lipid fractions

Whereas in patient E the insulin dose was decreased abruptly, in the other patient (F) the reduction was more gradual Similar lipid changes occurred but became

TABLE II—SERUM-LIPID LEVELS IN FIVE PATIENTS UNDER INSULIN CONTROL DURING STEADY STATE PERIODS ON DIFFERENT DIETS DATA FOR THE TRANSITION PERIODS ARE NOT INCLUDED

* Blood sugar levels were high during this period † No initial control period available (see text)

considerable only when the blood-sugar was allowed to rise to 400 mg per 100 ml or more

In both patients serum cholesterol and phospholipid remained at the low levels characteristic of the response to the diet rich in unsaturated fats The slight rise in β-lipoprotein lipid was therefore apparently due to an increase in triglyceride contained in the β complex

Discussion

Consideration of the origin and nature of hyperlipæmia in diabetes raises questions of great importance Hyperlipæmia undoubtedly exists in the untreated patient, it is promptly moderated by insulin therapy and is induced again in the treated patient if insulin is withheld In the experiments of Hirsch et al (1953) the hyperglycæmia induced in diabetics by withholding insulin was accompanied by hyperlipæmia, this consisting mainly in an increase in serum triglyceride Harris et al (1953) described a similar abnormality in diabetic acidosis, but also noted that other fractions of the serum lipids were involved in the resultant hyperlipæmia, which in their patients was often further exaggerated by hæmoconcentration

Wolff and Salt (1958) observed that in diabetic children under established insulin control the mean levels of serum β-lipoprotein lipid, cholesterol, and esterified fatty acid were correlated with the height of the blood-sugar levels

We are inclined to direct attention to the occurrence of hyperlipæmia in patients whose diabetes, though uncomplicated by ketonuria and acidosis, is not perfectly controlled, and many, if not most patients, fall into this group Of course hyperlipæmia is likely to be greatest in extreme decontrol with acidosis and ketosis, and we may here recall that juvenile diabetes has a tendency to ketoacidosis

Strisower et al (1958) showed by ultracentrifugal fractionation that diabetics in a non-acidotic decontrol phase had mild hyperlipæmia due mainly to an increase in the S_f0-12 lipoprotein class, in diabetics with acidosis there was pronounced hyperlipæmia due to gross increases in lipoproteins of the S_f20-400 classes and this was slightly offset by depletions of the S_f0-12 class and of the high-density lipoproteins Correlations between ultracentrifugal lipoprotein classes and paper-electrophoresis fractions (Smith 1957) have helped to elucidate these observations

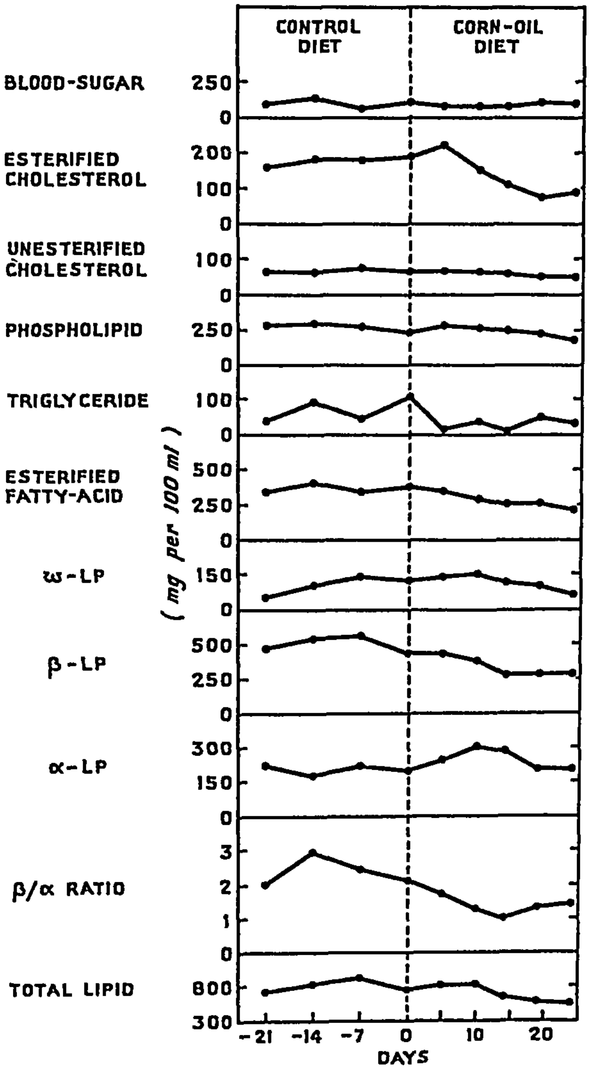

Fig 1—Effects of corn oil diet in patient B

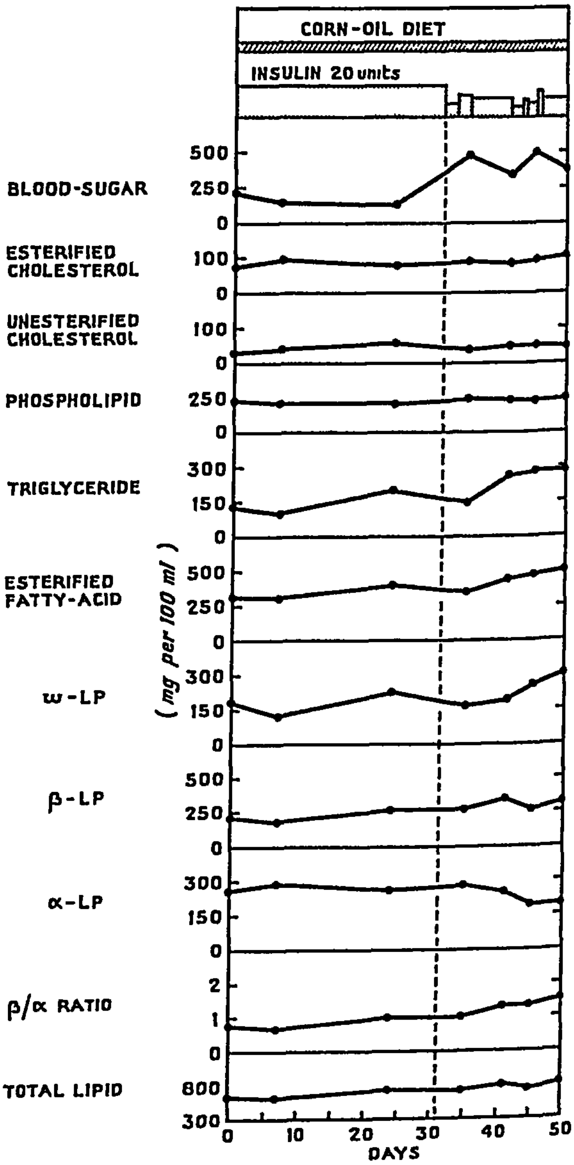

Fig 2—Effects of corn-oil in patient F

In discussing the nature and causes of diabetic hyperlipæmia, Albrink and Man (1958) stress the close relation between carbohydrate metabolism and serum-triglyceride concentration. They point out that some excess triglyceride can accumulate in the β-lipoprotein complex, the serum still being clear, but if greater amounts are present they must accumulate in the serum in particulate form. The serum is then turbid. On centrifugation at 18,000 r.p.m. for one hour, a cream-layer (chylomicrons) separates from a clear infranatant solution. We are in agreement with these observations, but have encountered certain sera from hitherto untreated cases in which the infranatant layer was not completely clear. The nature of the material causing the opalescence is under investigation; at present we suspect that it consists of β-lipoprotein containing an excess of triglyceride.

The mechanism responsible for accumulation of triglyceride in the diabetic remains obscure; failure to clear dietary fat is likely to play a part, but endogenous sources are also undoubtedly implicated. Albrink and Man emphasise that with persistent chylomicronæmia there is an associated excess of cholesterol and phospholipid commensurate with the triglyceride. Cholesterol may further accumulate in the β-lipoprotein complex. The excess cholesterol in the diabetic is thought to originate from increased production by synthesis from acetate fragments.

Our present results confirm that hyperlipæmia in diabetic children can be diminished by adequate insulin therapy, the serum triglyceride being mainly affected; and we show that the concentrations of certain serum lipid components, notably β-lipoprotein lipid, can be further diminished by feeding an unsaturated, instead of a saturated, type of dietary fat.

When sunflower-seed oil was fed, serum β-lipoprotein, esterified fatty acid, phospholipid, esterified cholesterol, and triglyceride were lowered. (The lowering of triglyceride may perhaps have been, partly at least, a result of unavoidable increases in insulin dosage.) On the corn-oil diet, serum esterified cholesterol, unesterified cholesterol, phospholipid, esterified fatty acid, and β-lipoprotein lipid were all lowered. Similar results have been reported in adult diabetics from the feeding of safflower-seed oil (Gordon 1957) and of vegetable (nut) oil (Kinsell et al. 1954).

The mechanism by which unsaturated dietary fat lowers the level of serum β-lipoprotein lipid is not clearly understood. Our observations suggest that a transfer of lipid from β- to α-lipoprotein may be an intermediate step, since α-lipoprotein was seen to rise transitorily at the time when β-lipoprotein was being lowered.

In the experiments designed to show the effects of insulin decontrol while the corn-oil diet was being fed, serum triglyceride and esterified fatty acid increased but cholesterol, phospholipid, and β-lipoprotein lipid remained low, showing that the influence of corn oil had persisted. This finding has a special significance for the diabetic in whom the disorder of carbohydrate metabolism, unless constantly well controlled, leads under usual dietary conditions to a rise in cholesterol, phospholipid, and β-lipoprotein lipid levels.

In the young diabetic prevention of vascular disease is the outstanding problem. The lipæmia of diabetes resembles in some respects that known to precede atheroma in older non-diabetic subjects. In both, the β-lipoprotein and cholesterol levels are raised; thus diabetic lipæmia could be a factor in the early development of vascular disease in the young. Though the serum lipids of diabetics can be kept within normal limits by perfect control, the practical difficulties of control are such that it is unlikely to be maintained constantly over long periods. Moreover, excessive insulin dosage must be avoided, because of the risk of hypoglycæmia, suppression of residual endogenous islet function, and development of insulin antagonists. Hence, additional control of lipæmia by dietary means demands a long-term trial.

Summary

In four previously untreated diabetic children, insulin therapy lowered the initially high values for serum triglyceride, β-lipoprotein lipid, esterified fatty acid, and phospholipid to normal within 24 or 48 hours. In one of the patients, in whom the serum-cholesterol level was initially high, insulin brought it down to normal.

In four patients under established diabetic control, observations of the diurnal variations of the various serum lipids and blood-sugar levels revealed a relative constancy of the lipid levels in the face of considerable variation in blood-sugar.

In thirteen diabetic patients under insulin control the effects of feeding unsaturated fats on the serum lipids were observed. Eight were given an emulsion of sunflower-seed oil; this led to a lowering of serum β-lipoprotein lipid, esterified fatty acid, phospholipid, esterified cholesterol, and triglyceride concentrations to levels below the control levels. Five were given a diet in which most of the usual (animal) fat had been replaced by corn oil. The isocaloric change from the control to the corn-oil diet led to a fall in esterified cholesterol and β-lipoprotein lipid to about 60% of the initial control levels, esterified fatty acid to about 75%, and unesterified cholesterol and phospholipid to about 80%.

In two patients on the corn-oil diet the effects of lessening the insulin dosage were observed. The cholesterol and phospholipid remained at low levels, but the diet did not prevent a rise in triglyceride, esterified fatty acid, and the ω (chylomicron) lipid fractions.

The hyperlipæmia of diabetes has similarities to that preceding atheroma in older non-diabetic subjects. It may play an important part in the causation of the vascular complications.

Hyperlipæmia could no doubt be prevented by perfect control of the diabetic process with insulin, but such control, however desirable, is rarely if ever maintained for long periods. As an additional controlling measure, a diet rich in unsaturated fat deserves long-term trial.

We gratefully acknowledge the help of Miss A. S. Fosbrooke, Mr. G. A. Brown, and Mr. B. T. Rudd in the analytical work, of Mr. A. E. Marston in preparing the sunflower-seed-oil emulsions, and of Sister H. R. Jukes in preparing the corn-oil diets. Unilever Ltd. gave us the sunflower-seed oil, and Alfonal Ltd. the corn-oil foods. We are grateful also to the endowment research fund of the United Birmingham Hospitals for financial support.

POTENTIATING EFFECT OF QUINOLINES ON THE ACTION OF TETRACYCLINE IN AMŒBIC DYSENTERY

S J POWELL
M B Cape Town, M R C.P E
A J WILMOT
D M Oxon, M R C P
R ELSDON-DEW
M D W'srand, F R S (S Af)
From the Amœbiasis Research Unit,[*] *Durban, South Africa*

THE usefulness of antibiotics in the treatment of amœbic dysentery is now widely accepted, and the tetracyclines have been shown to be the most valuable Tetracycline, chlortetracycline, and oxytetracycline are almost equally effective In a dosage of 1 g daily they produced in our hands immediate cure in 92–97% of cases (Elsdon-Dew et al 1952, Elsdon-Dew 1954–55) Their main disadvantages are expense, failure to prevent hepatic involvement, and a significant relapse-rate Because of this we have never claimed that tetracyclines can fully replace emetine as the treatment of choice Nevertheless these antibiotics are of great value for ambulant patients, and we now treat satisfactorily several thousand cases of amœbic dysentery each year as outpatients with tetracyclines together with diiodohydroxyquinoline

TABLE I—RESULTS OF TREATING 50 CASES OF AMŒBIC DYSENTERY WITH TETRACYCLINE, DIIODOHYDROXYQUINOLINE, AND CHLOROQUINE

Day of assessment	*10th*	*15th*	20th	27th	Cumulative (27 days)
Success	12 (*24%*)	31 (*62%*)	44 (*88%*)	47 (*94%*)	47 (*94%*)
Probable failure	38 (*76%*)	19 (*38%*)	6 (*12%*)	0	0
Parasitic failure	*0*	*0*	*0*	3 (6%)	3 (6%)

In the following trial our object was to see whether effective treatment could be given at lower costs, with small doses of tetracycline We also hoped to assess the effect of giving chloroquine and/or diiodohydroxyquinoline in addition

Material and Methods

Four drug combinations were tested

1 Fifty patients were treated with tetracycline 50 mg thrice daily for 10 days, diiodohydroxyquinoline 600 mg thrice daily for 20 days, and chloroquine sulphate 800 mg immediately, followed by 400 mg 6 hours later, and then 200 mg twice daily for 14 days

TABLE II—RESULTS OF TREATING 25 CASES OF AMŒBIC DYSENTERY WITH TETRACYCLINE AND DIIODOHYDROXYQUINOLINE

Day of assessment	10th	15th	20th	27th	Cumulative (27 days)
Success	6 (*24%*)	9 (*36%*)	14 (*56%*)	15 (*60%*)	15 (*60%*)
Probable failure	17 (*68%*)	11 (*44%*)	5 (*20%*)	3 (*12%*)	3 (*12%*)
Parasitic failure	2 (*8%*)	3 (*12%*)	1 (*4%*)	1 (*4%*)	7 (*28%*)

2 Twenty-five patients had tetracycline and diiodohydroxyquinoline in the above dosage, but no chloroquine

3 Twenty-five patients were given tetracycline and chloroquine in the same dosage as the first group, but no diiodohydroxyquinoline

4 Twenty-five patients had diiodohydroxyquinoline and chloroquine in the stated dosage, but no tetracycline

All were African males complaining of diarrhœa with blood and mucus, showing ulceration on sigmoidoscopy, and with actively motile *Entamœba histolytica* in the stools and ulcer scrapings Severely ill patients, and those with complications of coexisting disease, were excluded

Sigmoidoscopy was performed on admission and on the 5th, 10th, 20th, and 27th days after starting treatment Daily stool examinations were performed

Results were classified into the following categories

1 *Success*—Symptom-free, ulcers healed, and no parasites demonstrated

2 *Probable failure*—Persistent open ulceration, but no parasites demonstrable in stools or scrapings

3 *Parasitic failure*—Amœbæ still present, with or without open ulceration

TABLE III—RESULTS OF TREATING 25 CASES OF AMŒBIC DYSENTERY WITH TETRACYCLINE AND CHLOROQUINE

Day of assessment	10th	15th	20th	27th	Cumulative (27 days)
Success	4 (*16%*)	8 (*32%*)	8 (*32%*)	12 (*48%*)	12 (*48%*)
Probable failure	15 (*60%*)	14 (*56%*)	7 (*28%*)	1 (*4%*)	1 (*4%*)
Parasitic failure	6 (*24%*)	3 (*12%*)	7 (*28%*)	2 (*8%*)	12 (*48%*)

Cases which remained or became parasitic failures on or after completing their course of treatment under trial were removed at this point and given other treatment

Results

Tables I–IV indicate that in all groups the majority of patients still had open rectal ulceration at 10 days Thereafter the ulcers tended to heal But those who received only diiodohydroxyquinoline and chloroquine (table IV) tended to relapse as soon as their treatment was completed at the end of 20 days, so that by the 27th day only 20% could be classified as successes, and the combined failure-rate was 80% The group which had tetracycline and diiodohydroxyquinoline (table II) showed only a slightly better success-rate at 27 days (60%, with a combined failure-rate of 40%) than those who had tetracycline and chloroquine (48%, with a combined failure-rate of 52%) On the other hand the group which received both diiodohydroxyquinoline and chloroquine with tetracycline showed a success-rate at 27 days of 94% and a combined failure-rate of only 6%

TABLE IV—RESULTS OF TREATING 25 CASES OF AMŒBIC DYSENTERY WITH DIIODOHYDROXYQUINOLINE AND CHLOROQUINE

Day of assessment	10th	15th	20th	27th	Cumulative (27 days)
Success	6 (*24%*)	13 (*52%*)	14 (*56%*)	5 (*20%*)	5 (*20%*)
Probable failure	15 (*60%*)	8 (*32%*)	8 (*32%*)	4 (*16%*)	4 (*16%*)
Parasitic failure	4 (*16%*)	4 (*16%*)	3 (*12%*)	13 (*52%*)	16 (*64%*)

Follow-up Studies

Follow-up was incomplete But of those patients who received *all* three drugs three had relapsed within a month, giving a total failure-rate of 12% Three relapsed in the tetracycline and diiodohydroxyquinoline group, and one in the tetracycline and chloroquine group, giving total

TABLE V—RESULTS OF FOLLOW-UP OF 27-DAY "SUCCESSES" 1 *MONTH* AFTER DISCHARGE

—	*No of* successes available	No who attended	No of failures	Total failure-rate
Tetracycline, diiodohydroxyquinoline, and chloroquine	47	32 (*68%*)	3 (*6%*)	*12%*
Tetracycline and diiodohydroxyquinoline	*15*	*5 (33%)*	3 (*20%*)	*52%*
Tetracycline and chloroquine	12	6 (*50%*)	1 (*8%*)	*56%*
Diiodohydroxyquinoline and chloroquine	5	3 (*60%*)	1 (*20%*)	*84%*

---

[*] *The Amœbiasis Research Unit is sponsored by the South African Council* for Scientific and Industrial Research, the Natal Provincial Administration, the University of Natal, and the United States Public Health Service (grant E-1592)

failure-rates of 52% and 56% respectively Of those who had duodohydroxyquinoline and chloroquine alone one relapsed, giving a total failure-rate of 84%

Discussion

The use of a systemic amœbicide, such as chloroquine, together with antibiotics, in the treatment of amœbic dysentery is fully justified to prevent hepatic complications Chloroquine is valuable in hepatic amœbiasis though it has little effect in dysenteric forms of the disease Our results, however, show a striking increase in the cure-rate when chloroquine and duodohydroxyquinoline are given in association with suboptimal doses of tetracycline

Armstrong et al. (1955) found that chlortetracycline in a dosage of 80 mg daily for 10 days gave a success-rate of 63% at 10 days, but by the 27th day this had fallen to 53%, with a total failure-rate of 47% In a further series they therefore gave a combination of chlortetracycline 100 mg daily for 10 days, duodohydroxyquinoline 600 mg thrice daily for 20 days, and chloroquine 500 mg daily for 15 days, and achieved a satisfactory success-rate of 85% at 10 days, and of 91% at 27 days, with a total failure-rate of only 6% The improved response in this series was ascribed to the addition of duodohydroxyquinoline, and the possible role of chloroquine was not emphasised.

The results of the present trial lead to surprising conclusions Earlier trials of duodohydroxyquinoline gave a success-rate of 58% at 20 days (Armstrong et al 1949) which corresponds with the success-rate of 56% at 20 days now obtained with duodohydroxyquinoline and chloroquine combined In other words, the addition of chloroquine to duodohydroxyquinoline did not affect the success-rate Moreover, a high proportion of these patients have now been shown to relapse immediately the drugs are discontinued

Armstrong et al. (1955) had a success-rate of 53% with small doses of chlortetracycline We have now shown that the addition of either duodohydroxyquinoline or chloroquine did not significantly increase the successes But when the three drugs were used together the proportion of successes rose strikingly to 94% This seems to indicate that tetracycline in small doses is the most effective drug, but in order to achieve a high proportion of successes the addition of both chloroquine and duodohydroxyquinoline is necessary Whenever dysenteric amœbiasis is treated with tetracyclines, therefore, it seems reasonable that chloroquine should be given in addition to duodohydroxyquinoline not only to safeguard the liver but also because of the enhanced efficacy of combined therapy

When tetracycline 1 g daily was given for 10 days the rectal ulcers were healed in 89% of patients by the 10th day, and in 94% by the 15th day (Elsdon-Dew 1954–55) By contrast, when tetracycline 150 mg daily was given with duodohydroxyquinoline and chloroquine, the ulcers were healed in only 24% of patients by the 10th day, and in 62% by the 15th day Thus when tetracycline is used in small doses the rate of healing of ulcers is considerably slower, although the end-result is satisfactory In view of the slower clinical response and less rapid healing of ulcers tetracycline in small doses is not recommended in acute amœbic dysentery, but it may be justified sometimes where reducing the cost is vital

Summary

Amœbic dysentery has been treated with four drug combinations

1 Fifty cases had both chloroquine and duodohydroxyquinoline in addition to suboptimal doses of tetracycline

2 Twenty-five cases were given suboptimal doses of tetracycline with duodohydroxyquinoline.

3 Twenty-five cases had suboptimal doses of tetracycline with chloroquine.

4 Twenty-five cases were given duodohydroxyquinoline and chloroquine

Although the addition of either chloroquine or duodohydroxyquinoline to small doses of tetracycline had little effect, a combination of the two drugs with tetracycline resulted in an immediate cure-rate of 94% This compares favourably with the results from using tetracycline in the usual dosage, although the ulcers heal more slowly

We should like to thank Dr S Disler, superintendent, King Edward VIII Hospital, Durban, for facilities

PSEUDOXANTHOMA ELASTICUM

G M Berlyne
M.B Manc., M.R.C.P

TUTOR IN MEDICINE, UNIVERSITY DEPARTMENT OF MEDICINE, MANCHESTER ROYAL INFIRMARY

Diagnosis depends primarily on the physician's high index of suspicion for certain symptom complexes, this is particularly important in the "rare" diseases, many of which are more prevalent than the sparseness of case-reports would indicate In this paper I direct attention to the disease known as pseudoxanthoma elasticum (P.X.E), or the Grönblad-Strandberg syndrome, in which widespread alteration in the elastic tissue produces a characteristic skin appearance, angioid streaking of the retina, and sometimes gastrointestinal bleeding which may be fatal. Every case of hæmatemesis and melæna should be examined for evidence of P.X E in order to avoid unnecessary surgical intervention (McKusick 1956) My first patient was recognised thus during systematic examination in the casualty department of the Manchester Royal Infirmary.

Case-reports

Case 1—A 22-year-old, single, shorthand-typist gave a history of gradually deteriorating vision of her left eye for 6 months She was otherwise well until 3 days before admission to hospital, when she noticed that she was passing black tarry stools She was not taking any medicine On the morning

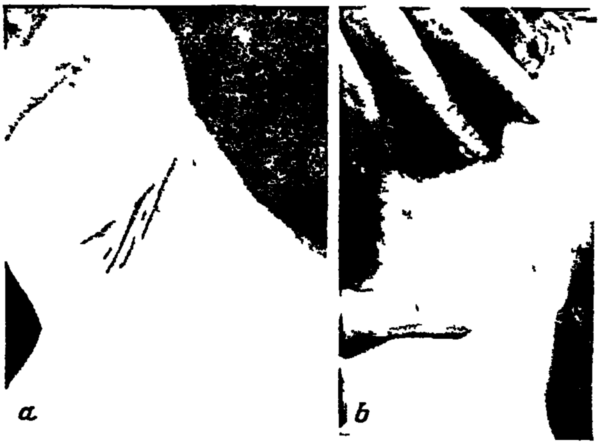

Fig 1—Case 1 (*a*) redundant folds of skin of the neck, (*b*) coarse-grained appearance of the skin

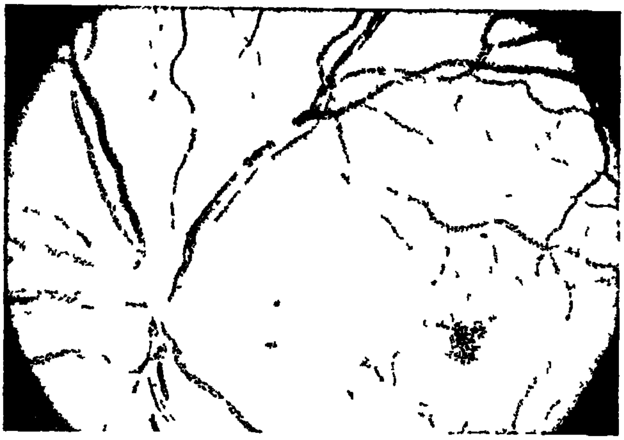

Fig 2—Case 1 Retinal photograph showing angioid streaks and pigmentation in the region of the macula

before admission she felt faint and dizzy on running upstairs, and this persisted for 5 minutes Next day (Nov 7, 1958) she rose at 5 A M to micturate and fainted on standing upright Later in the day she felt something in her throat, and then vomited a large amount of dark red blood, containing clots She had no abdominal pain She had not had any serious illness previously

Examination

She was slightly distressed The skin of her neck showed redundant folds and was covered with numerous yellow plaques (fig 1), some of which had apparently suppurated recently The skin of the axillæ, antecubital fossæ, and groins was affected similarly, otherwise the limbs were normal Her mucosæ were pale, there were no buccal lesions Both optic fundi showed numerous angioid streaks, and the left macula was pigmented (see fig 2) Visual acuity was J20 in the left eye and J1 in the right eye (uncorrected) The cardiovascular system was normal except for absence of the posterior tibial pulses

On admission her blood-pressure was 130/80 mm Hg, and her pulse-rate 120 per minute and regular The respiratory system and abdomen were normal The fingers were not clubbed, and there were no spider nævi Rectal examination was normal apart from melæna

Gastrointestinal hæmorrhage due to the Grönblad-Strandberg syndrome (P X E with angioid streaks in the retina) was diagnosed

Further Investigations

A skin-biopsy specimen from the right antecubital fossa was taken on Nov 11 The histological report was

> The epidermis and superficial quarter or fifth of the dermis shows changes in the elastic fibres, they are greatly increased in bulk, with bulbous or irregular swelling, and extensively fragmented Von Kossa's method shows widespread calcification of these fibres An occasional " foreign-body " giant-cell is seen alongside altered elastic fibres, but there is no other cellular reaction The collagen fibres appear more or less normal, there is perhaps a little focal formation of slender new fibres The picture is that of P X E (figs 3a and b)

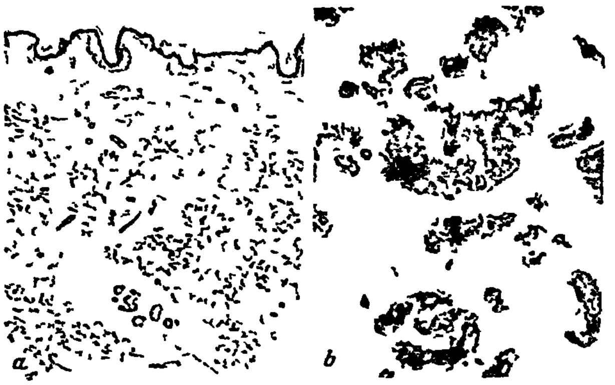

Fig 3—Skin-biopsy specimen of case 1 (*a*) showing degeneration of elastic fibres (Verhoff-Van Gieson stain for elastic tissue ×30), (*b*) showing calcification of the elastic tissue (Von Kossa's reaction for calcium ×225)

An electrocardiogram and a chest radiograph were normal Radiographs of the lower limbs showed no calcification in muscles or vessels At barium-meal examination the outline and mucosal patterns of the œsophagus, stomach, and duodenum were normal, and there was no evidence of peptic ulceration

A full blood-count on Nov 11 showed Hb 48% (7 2 g per 100 ml), colour-index 1 0, white-cell count 8100 per c mm. (polymorphonuclears 69 5%, lymphocytes 27%, monocytes 2%, and eosinophils 1 5%), platelets 360,000 per c mm, and erythrocyte-sedimentation rate (Wintrobe) 10 mm in the 1st hour Tests for occult blood in the fæces were strongly positive Prothrombin activity was 100%

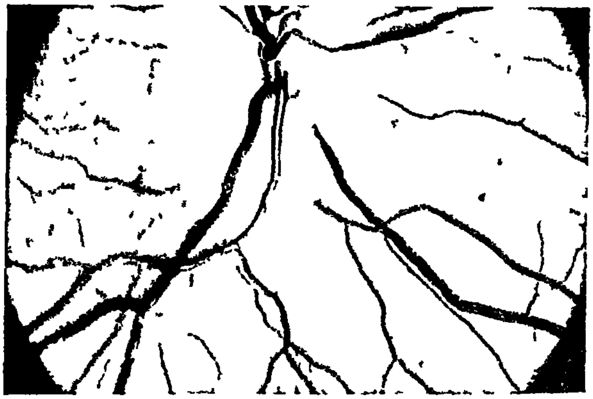

Fig 4—Case 2 Retinal photograph showing numerous angioid streaks

Liver-function tests showed serum-albumin 3 4 g per 100 ml, globulin 2 6 g per 100 ml, bilirubin 0 8 mg per 100 ml, thymol-turbidity 0 8 unit, alkaline phosphatase 6 5 King-Armstrong units, serum-glutamic-oxaloacetic-transaminase 7 units per ml, serum-protein electrophoresis normal, serum-free-cholesterol 45 mg per 100 ml, ester-cholesterol 140 mg per 100 ml, and phospholipids 200 mg per 100 ml The total fatty acids were 290 mg per 100 ml, neutral-fat content was 55 mg per 100 ml, serum-calcium 10 mg per 100 ml, and serum-inorganic-phosphorus 2 9 mg per 100 ml

Progress

The hæmoglobin (Hb) on admission was 56% (8 g per 100 ml) She was given a transfusion of 2 pints of whole blood, but next day her Hb had fallen to 38% (5 6 g per 100 ml), and she was given a further 10 pints of blood over the next 5 days, while she continued to pass melæna stools The melæna abated by Nov 12, when her Hb had risen to 76% (11 4 g per 100 ml) Her blood-group was O (rhesus-positive) She was treated at first by a modified Meulengracht regimen She was discharged symptom-free on Dec 12, and has remained well When last seen on Jan 14, 1959, her Hb was 92% (13 6 g per 100 ml)

Family history

All members of the patient's immediate family were examined Both parents were healthy, with no skin or retinal abnormality and no history of gastrointestinal bleeding or peptic ulceration A brother, aged 18, was unaffected, but a sister, aged 14, had both skin and retinal manifestations of the Grönblad-Strandberg syndrome (case 2)

Case 2 —This girl had no symptoms Her skin showed the typical changes of P X E. She was normotensive The retinal appearances were similar to those of her sister—namely, angioid streaks and perimacular pigmentation (fig 4) She had never had gastrointestinal bleeding Skin biopsy was not performed, nor, unfortunately, was visual acuity determined

Discussion

The skin manifestations of P X E were first described in 1884 by Balzer, who classified the disease as one of the xanthomatoses This was corrected by Darier (1896), who named the syndrome pseudoxanthoma elasticum, and defined the histological changes in the skin The symptom-complex of skin and retinal changes associated with gastro-intestinal hæmorrhage, failing vision, and weak peripheral pulses in the same patient, was gradually unfolded in several papers over the course of 14 years, starting with Chauffard's description in 1889, followed by Besnier and Doyon (1891), Darier (1896), and finally Hallopeau and Lafitte (1903) The connection between skin and retinal changes was first clearly indicated in the classical papers of Grönblad (1929) and Strandberg (1929), because of which the disease enjoys the eponymous title of the Gronblad-Strandberg syndrome

Clinical Features

The clinical manifestations of the disease are all dependent on the widespread degeneration of elastic fibres Collagen itself is not affected directly (Moran and Lansing 1958) The two most striking features are the changes in the skin and retina, but there are less constant manifestations—namely, gastrointestinal hæmorrhage, intermittent claudication, weakness or absence of peripheral pulses by the third decade, dilatation of the aorta, and mental changes

Skin changes may not appear before the second decade, although in the two cases here reported and in two sisters described by Worringer and Gerhard (1957) the skin changes were noticed in the first decade The sites of abnormal skin are the neck, axillæ, antecubital areas, inguinal folds, and periumbilical region The affected skin is coarser and thicker than normal, looking rather like coarse-grained Moroccan leather or a plucked chicken (Szymanski and Caro 1955), the elevations being slightly yellow The skin is often prone to pyogenic infections, elasticity is lost, and it hangs in redundant folds, particularly in the axillary and inguinal regions Buccal, rectal, and vaginal changes have been described (Giesen 1936, Carlborg 1944) But the skin may appear normal to the naked eye although histologically abnormal

Eye changes.—The typical change is angioid streaking of the optic fundus, although this is not always the only finding Angioid streaks are lines fanning out from the optic disc, which vary in colour from grey to red-brown They may be due to degeneration of elastic fibres causing cracking of Bruch's membrane, or, as Scholz (1941) suggested, to pigmentation in affected vessels Angioid streaks may occur also in Paget's disease (Scholz 1941) Other retinal manifestations are macular or perimacular hæmorrhages, colloid bodies (white or yellow discs), and central choroidoretinitis Blindness may ultimately occur

Gastrointestinal bleeding.—Massive gastrointestinal hæmorrhage is common (Kaplan and Hartman 1954), and may occasionally be fatal McKusick (1956) thinks this complication is so important that in all cases of gastro-intestinal hæmorrhage the physician should make a special search for skin changes Some patients have numerous hæmatemeses before the diagnosis of P X E is established finally Occasionally the diagnosis is only made on histological examination of the stomach after gastrectomy (Edwards 1958) Often the entire mucosal surface of the stomach oozes blood, there being no discrete bleeding point suitable for surgical attack Histologically there are often numerous microaneurysms, due to elastic-tissue degeneration in the gastric arteries, with intimal obliterative sclerosis Four cases of P X E with gastrointestinal hæmorrhage during pregnancy have been described, one of which underwent partial gastrectomy (McCaughay et al 1956, Woo and Chandler 1958) In view of the increase during pregnancy of factors which relax tissue (Allen et al 1939), one might speculate that the mechanism of bleeding is a summation of the effect of pregnancy and damage to elastic tissue in the gastrointestinal arteries Medical treatment seems desirable for patients with P X E and gastrointestinal hæmorrhage rather than surgical exploration, with the almost inevitable sequel of partial gastrectomy, which can be of little benefit when the entire mucosal surface of the stomach is oozing blood Symptoms of peptic ulceration are unusual Barium-meal examination rarely demonstrates an ulcer crater (Van Embden Andres 1952) Hæmorrhages from nose, uterus, and bladder, and into the subarachnoid space have been reported, also spontaneous hæmarthroses and purpura, without disturbance of the clotting factors The peripheral arteries may become calcified due to premature arteriosclerotic changes brought about indirectly by the damaged elastic tissue This may cause intermittent claudication, with absent or diminished peripheral pulses and peripheral arterial calcification demonstrable radiographically in the legs (McKusick 1956) The arterial degeneration may cause hypertension, intracranial aneurysm, coronary sclerosis with angina pectoris, or aortic aneurysm

Prognosis

The life prognosis in P X E is good, although patients may die from torrential gastrointestinal bleeding, or from premature coronary atheroma or hypertension Blindness is common and is often the reason medical advice is sought The occular complications cannot be treated effectively

Genetics

P X E is rare in successive generations but multiple involvement in individual sibships is high, indicating that the mode of inheritance is probably recessive This should give a ratio of affected/unaffected siblings of 1/3, instead of 1/1 as in most reported cases, but this discrepancy may be due to faulty sampling Remarkably few detailed kinships of P X E have been described, thus precluding adequate statistical investigation of the genetics of the disease

Touraine (1940a and b, 1941) found that more females than males were affected, of a hundred and sixty-five cases a hundred and four were female Cockayne (1933) suggested that P.X.E was partly sex-limited to the female McKusick (1959) thinks transmission is by an autosomal recessive gene, but he fails to explain the greater prevalence in females Hermann (1956) concluded that the P.X E. gene is usually dominant, but admitted that it may occasionally be recessive Until more case-reports with adequate family histories are published these statements cannot be subjected to adequate statistical analysis

Summary

Pseudoxanthoma elasticum (Gronblad-Strandberg syndrome) is described in two sisters

The clinical manifestations are (1) characteristic coarsening and elasticity of the skin due to widespread degeneration of elastic fibres, (2) angioid streaking of the retina causing visual deterioration, and sometimes (3) gastro-intestinal bleeding, which can be fatal

Genetically the syndrome is probably due to a recessive gene

In management active but conservative treatment of gastrointestinal bleeding is important

My thanks are due to Dr H T Howat for permission to publish these cases, and for many valuable suggestions, to Prof D A K Black for constructive criticism, and to Sir Robert Platt for encouragement and discussion, particularly of the genetic aspects I am indebted to Prof A C P Campbell for the biopsy report and the photomicrographs, to Dr R G W Ollerenshaw of the department of medical illustration for the clinical photographs, and to Dr P J D Snow for the retinal photographs

SALMONELLA OSTEITIS IN NIGERIAN CHILDREN

R G HENDRICKSE
M D Cape Town, M R C P E
LECTURER IN PÆDIATRICS

PATRICK COLLARD
M D Lond, M R C P
PROFESSOR OF BACTERIOLOGY

UNIVERSITY COLLEGE, IBADAN, NIGERIA

SALMONELLA osteitis is a rare clinical entity, by 1950 only nineteen cases had been recorded (Wigh and Thompson 1950) Patients with sickle-cell anæmia, however, seem to be peculiarly susceptible to this complication Hodges and Holt (1951) first drew attention to the relation between sickle-cell anæmia and salmonella infections, though isolated examples had been reported as early as 1937 (Diggs et al 1937)

Vandepitte et al (1953) described five cases of salmonella osteitis seen in patients with sickle-cell anæmia in the Belgian Congo, and mentioned the association Earlier a greater susceptibility to salmonella infections had been observed among sicklers than non-sicklers in the Belgian Congo (Lambotte-Legrand and Lambotte-Legrand 1951) In 1957 Hook et al were able to find twenty-nine reported instances, and to add four new cases of their own In 1958 Roberts and Hilberg described four more cases of salmonella osteitis complicating sickle-cell disease, one of their patients having sickle-cell hæmoglobin-C disease It has become increasingly apparent that the occurrence of salmonella osteitis and sickle cell anæmia is not merely fortuitous The *British Medical Journal* (1957) stated " It seems therefore established that there is a highly significant association between salmonella osteitis and sickling," and drew attention to the possibility, suggested by the Lambotte-Legrands (1951) and Raper (1956), that carriers of the sickle-cell trait might be more liable to salmonella infections than non-sicklers, which would call for reorientation of " our conceptions of the population dynamics of sickling "

TABLE I—SALMONELLA OSTEITIS IN PATIENTS WITH SICKLE-CELL ANÆMIA

Case no	Age (yr)	Sex	Site	Bacteriology
1	9	M	Both ulnæ, left radius, both tibiæ	Salmonella isolated from blood, serum agglutinated *S dublin* (g p) 1/1280 and *S typhi* O (9, 12) 1/320
2	$1^{1}/_{4}$	F	Multiple phalanges, metacarpals, metatarsals, and left radius	Salmonella belonging to group B isolated from pus and stools
3	3	M	Both femora	Salmonella isolated from blood, serum agglutinated *S typhimurium* H (i) 1/1280
4	$^{3}/_{4}$	M	Left radius, multiple phalanges of feet	Serum agglutinated *S typhi* O (9, 12) 1/640, *S enteritidis* H (g m) 1/1280, and *S menston* H (g s t.) 1/640
5	1	F	Bilateral metatarsals	*S dublin* isolated from pus
6	$3^{1}/_{4}$	M	Bilateral radii, ulnæ, and tibiæ	Serum agglutinated *S paratyphi C* O (6, 7) 1/320, and *S paratyphi C* H (c) 1/1280
7	$1^{1}/_{4}$	F	Bilateral metatarsals and right ring finger	*S dublin* isolated from pus, serum agglutinated *S dublin* H (g p) 1/1280, *S menston* H (g s t.) 1/640, and *S london* O (3, 10) 1/160

The object of this paper is to report thirteen cases of salmonella osteitis seen in the children's department of University College Hospital, Ibadan, between June, 1956, and October, 1958 In seven instances infection was in a proved case of sickle-cell anæmia One patient was a non-sickler In the other five patients sickling tests were not performed One of this group was an 8-day-old infant, and, in view of the known paucity of sickled cells in the blood of the newborn (Watson et al 1948), it seems highly unlikely that sickling per se was related significantly to the infection

Clinical Findings

SALMONELLA OSTEITIS IN SICKLE-CELL ANÆMIA

Table I shows the age, sex, sites involved, and bacteriology in seven cases of sickle-cell anæmia complicated by salmonella osteitis All recovered on chloramphenicol, but in the majority the response was slow, and treatment had to be continued for long periods

Illustrative Case-report (Case 7)

A Yoruba girl, aged 15 months, presented with painful swelling of the hands and feet of 4 days' duration, associated

TABLE II—SALMONELLA OSTEITIS IN FIVE PATIENTS WHOSE HÆMOGLOBIN GENOTYPES WERE NOT KNOWN, AND IN ONE NON-SICKLER

Case no	Age	Sex	Site	Bacteriology	Comment
8	3 mos	F	Left humerus and left scapula	*S enteritidis* isolated from stools and pus	Anæmia, hepatosplenomegaly, terminal bronchopneumonia, died
9	1 yr	F	Right femur (lateral condyle)	*S enteritidis* isolated from pus	Hæmoglobin 60%, general condition good, no hepatosplenomegaly, good recovery
10	8 days	F	? Left femur	*S enteritidis* isolated from blood	Toxic deeply jaundiced premature infant, died within 12 hours of admission
11	9 mos	F	Right scapula	*S chasley* isolated from pus	Not anæmic, good recovery
12	$5^{1}/_{2}$ yr	F	Both tibiæ	*S ank* ('new species ') isolated from pus	
13	14 mos	F	Right knee, left humerus	*S saint paul* isolated from pus from both sites	Non-sickler, hæmoglobin 38%, presented with diarrhœa, dehydration, and bronchopneumonia, osteitis apparent 11 days after admission, good recovery

with fever She was pyrexial and anæmic. There were tender brawny swellings over the dorsum of both feet, and a tender fluctuant swelling over the proximal phalanx of the right ring finger The liver was palpable No other abnormality was found clinically

Special investigations—Hæmoglobin 6 1 g per 100 ml, white blood-cell count 18,800, sickling positive, hæmoglobin electrophoresis showed hæmoglobin S only Pus aspirated from the ring finger grew *Salmonella dublin* on culture The serum agglutinated the following

S dublin H (g p) at 1/1280
S menston H (g s t.) at 1/640
S london O (3, 10) at 1/160

Radiographs taken when the patient first attended showed changes attributable to sickle-cell anæmia only, but later films showed osteitis of several metatarsals and the proximal phalanx of the right ring finger

Progress—The child was treated with chloramphenicol, and the osteitis resolved completely

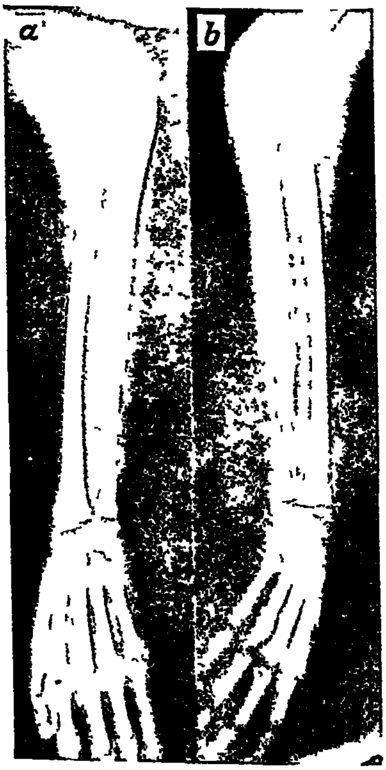
SALMONELLA OSTEITIS IN PATIENTS WITH UNKNOWN HÆMOGLOBIN GENOTYPES, AND IN A NON-SICKLER

Table II shows the age, sex, site, salient clinical features, and bacteriology in five cases of salmonella osteitis in which the hæmoglobin genotypes were not known, and in one patient who was a non-sickler All were treated with chloramphenicol except case 11, which appeared to respond to chlortetracycline

Discussion

These thirteen cases represent the largest series of salmonella osteitis described to date Unfortunately, information about erythrocyte sickling is not available in five Taking into account the many cases of sickle-cell anæmia in the Ibadan area (25% of the population show the sickle-cell trait [Garlick and Barnicot 1957]), some of these are likely to have been cases of sickle-cell anæmia The clinical findings in one instance (case 8) were highly suggestive of the disease. Our finding seven examples of salmonella osteitis in proven cases of sickle-cell anæmia supports the observation that people with sickle-cell anæmia are peculiarly susceptible to this complication There can be little doubt that the association is significant

Ten of our thirteen cases were seen during the months of July to November Conclusions about the seasonal incidence of salmonella osteitis cannot be drawn from so small a series, but analysis of the monthly isolations of salmonellæ in Ibadan during 1956 showed a definite peak incidence during the months of June, July, and August (Collard and Sen 1958), when the rainy season is at its height. The observed incidence of osteitis in our cases correlates with Collard and Sen's findings if we allow a time-lag between bowel infection and the onset of osteitis In five cases we obtained a clear history of diarrhœa preceding the osteitis, and in two, identical strains of salmonellæ were isolated from pus and stools



Figs. 1—Case 1 Salmonella osteitis in sickle-cell anæmia, showing bilateral symmetrical involvement of ulnæ.

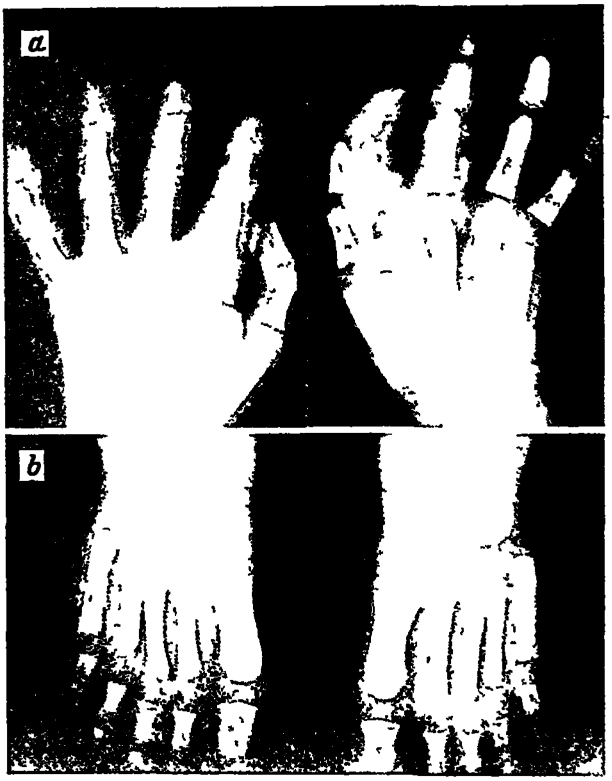


Fig 2—Case 2. Salmonella osteitis in sickle-cell anæmia involving many bones in hands and feet Note the symmetrical involvement of the index figures and fifth metatarsals

In our series salmonella osteitis was most frequent in the first 2 years of life, nine of our thirteen cases fall into this age-group Other reports also show a higher incidence in this age-group than at any other time (see Hook et al 1957, Roberts and Hilberg 1958) This finding is probably determined by

(1) The high incidence of gastrointestinal infections during infancy, especially in underdeveloped areas

(2) The progressive fall in the number of patients with sickle-cell anæmia seen in successive age-groups This results mainly from increase in mortality but the observed tendency for the disease to become attenuated with age may be a contributory factor (Lambotte-Legrand and Lambotte-Legrand 1951, 1955, Trowell et al 1957, Scott et al 1955, Hendrickse 1959)

Until 1957 reports indicated that males were more often affected than females (3/1), and that *S paratyphi B* or *S typhimurium* accounted for 67% of infections (Hook et al 1957) Our own findings differ Nine cases were female and four were male, and eight different species of salmonellæ were isolated The only organism frequently encountered was *S enteritidis*, which was found in four cases The majority of the eight types isolated belonged to serotypes associated with an invasive clinical picture

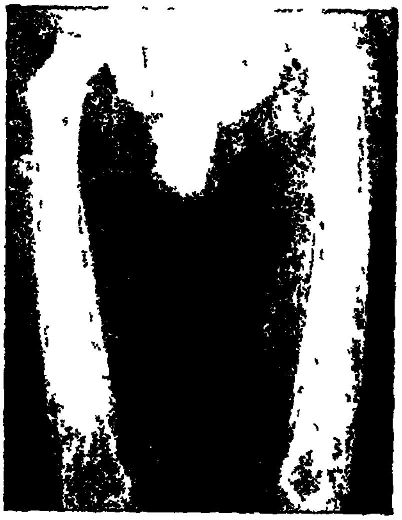

Fig 3—Case 3 Salmonella osteitis in sickle-cell anæmia, with bilateral symmetrical involvement of femora

Sickle-cell anæmia often masquerades as osteitis These patients are prone to episodes of fever, accompanied by pain and sometimes swelling over bone, associated with leucocytosis and sometimes radiological changes in bone due to infarction Clinically these episodes are virtually indistinguishable from acute osteomyelitis except by their course and response to treatment When osteomyelitis does arise, the clinical picture varies very little with different pathogens, except in the response to treatment In general, salmonella osteitis responds only to chloramphenicol, but even with optimum dosages of this drug response is slow, and relapses tend to follow months or even years after apparent eradication of infection (Hook et al 1957)

Table I and figs 1–3 show that multiple sites were affected in all our cases, and that in some the lesions were bilateral and symmetrical This agrees with other reports (Smith 1953, Vandepitte et al 1953, Hook et al 1957, Hughes and Carrol 1957, Wigh and Thompson 1950, Goldenberg 1955) Such a distribution of osteitis is not peculiar to salmonella infections but is seen with other organisms as well Further, the sites most often affected by osteitis are similar to those most often involved in the spontaneous peripheral manifestations of sickle-cell anæmia The obvious inference is that areas devitalised by the pathological processes peculiar to the disease become infected by a transient bacteræmia, which in normal persons usually has no serious consequences Two other factors probably also contribute to the high incidence of salmonella osteitis in sickle-cell anæmia (1) Capillary thrombosis consequent on intravascular sickling, which probably decreases the resistance of the gastrointestinal tract to invasion by pathogens, and (2) salmonellæ may remain dormant in bone-marrow for long periods (Vandepitte et al 1953, Roberts and Hilberg 1958)

Normal people harbouring the organism usually remain symptom-free, though occasionally localised circumscribed areas of osteitis (Brodie's abscess) may arise In sickle-cell anæmia debility lowers the general resistance to infection, and thrombotic episodes in hæmopoietic tissue and bones lowers local resistance In these circumstances active infection is to be expected sooner or later in anyone harbouring the organism

Autosplenectomy in sickle-cell anæmia has been suggested as an additional factor in lowering resistance to infection and predisposing to invasion by salmonellæ (Hook et al 1957) While the theoretical grounds for this suggestion cannot be contested, most cases of salmonella osteitis reported are of an age where autosplenectomy is rare Among more than two hundred cases of sickle-cell anæmia under 10 years of age seen in the children's department at University College Hospital, Ibadan, more than 70% had splenomegaly, and autosplenectomy was not observed Thus in our series autosplenectomy does not seem to be a significant factor in determining salmonella osteitis in sickle-cell anæmia

Summary

Thirteen cases of salmonella osteitis in Nigerian children are reported In seven cases salmonella infection complicated sickle-cell anæmia, in five erythrocyte sickling was not looked for, and one patient was a non-sickler

Our findings suggest a seasonal incidence, and indicate that salmonella osteitis is commonest during the first 2 years of life Eight strains of salmonellæ were isolated *Salmonella enteritidis* was found in four cases

The peculiar susceptibility to salmonella osteitis of persons with sickle-cell anæmia may be due to (1) diminished resistance of the gastrointestinal tract to invasion by pathogens, and (2) diminished resistance to infection in the hæmopoietic tissue and bones These both result from tissue ischæmia following intrascular sickling and thrombosis Autosplenectomy is unlikely to have any great significance in determining the incidence

INDUCTION OF ANÆSTHESIA IN YOUNG CHILDREN *

R J Hamer Hodges
F F A R C S
ANÆSTHETIST, PORTSMOUTH GROUP OF HOSPITALS

MANY studies of the psychotraumatic aspects of pædiatric surgery and anæsthesia have shown that not all young children survive a stay in hospital unscathed (Gwathmey 1936, Coleman 1950, Albany Research Project 1952, Eckenhoff 1953, Levy 1955, Junkin 1956) The possible causes of psychic trauma (nursing, anæsthesia, surgery, maternal separation) are not segregated easily, though some reports dissociate unjustifiably the induction of anæsthesia from the general adverse effects Failure to provide suitable sedative premedication is often regarded as a major ætiological factor in late psychic upsets (Slater and Stephen 1951) Unfortunately, therefore, efforts have been directed primarily towards improving premedicant drugs (Slater and Stephen 1951, Rendell 1954, Gusterson 1955, 1957) rather than towards lessening the general psychic trauma of surgery and anæsthesia Incidentally premedication itself may lead to psychic trauma (Barnes 1952, Ellison 1955, Goulding et al 1957, Halstead 1955, Rollason 1955, Morton 1957)

---

* Being part of a paper gaining a research prize awarded by the South West Metropolitan Regional Hospital Board, 1958

In most children subjected to “everyday” surgical procedures adequate sedative premedication is either contraindicated or impossible. Of nearly nine thousand such children anæsthetised in 1957 in one hospital group, 90% were outpatients or underwent otolaryngeal procedures (Hodges 1959) I believe that failure lies not in lack of premedication but in the way the children are approached and in their reactions to an unpleasant anæsthetic experience

In a large series of unpremedicated or lightly premedicated children I gained the impression that an anæsthetic technique based on either a single dose of thiopentone, or on thiopentone and nitrous-oxide/oxygen (with suxamethonium where necessary in the longer procedures) lessened some of the untoward sequelæ associated with induction and recovery from the anæsthetic

Psychiatrists strongly support the belief that neither docile resignation nor an outward calm in the face of disturbing circumstances indicates reliably a child's emotional state Hence I thought that further study of the true emotional state was necessary before the technique of inducing anæsthesia intravenously in children with little or no premedication is accepted as successful

The Patients

Children having their tonsils and adenoids out (the most common operation in elective pædiatric surgery) are ideal for studying the psychic trauma of introduction to hospital In otolaryngeal surgery many think that sedative premedication is contraindicated These patients, therefore, fulfil the criteria for “everyday” anæsthesia Their basic reactions to environment and experiences, unmasked by drug sedation, can be studied, providing a baseline for the assessment of premedicant drugs

A hundred and fifty-five children admitted consecutively for adenotonsillectomy were studied They were aged from 3 to 12 years, but they mostly fell into the 4½–7½ age-groups (fig 1)

Children with whom one cannot establish contact (usually, though not invariably, the under-3-year age-group) constitute a special problem. Therefore those who could not be approached verbally because of age (three patients), language difficulties (three patients), or congenital maldevelopment (four patients), were excluded from the series Three children over the age of 10½ years were excluded also because in this more mature group the problems are less Thus a hundred and forty-two children remained in the series

Method

Admission

24 hours before surgery, the children were admitted to an ear, nose, and throat surgical ward catering exclusively for them. Children in various stages of their hospital stay were intermingled, and, as far as their surgical condition allowed, encouraged to play together They were screened from the rest of the ward immediately before and after operation, and no new patients were admitted meanwhile. The short-stay routine surgical patients were not visited by their parents

Preoperative Approach

My practice is to visit these children on the morning of admission. The necessity for a “psychological approach” to children has been stressed often (*British Medical Journal* 1954, Leigh 1949, Collins and Granatelli 1956), and the advantages of intelligent cooperation are obvious

The technique is not, as many think, time-consuming These children were treated satisfactorily as a group, and no more than 20 minutes was spent in the essential preoperative examination and explanation. I hold what I call a “pre-anæsthetic class” for the ten to fifteen children scheduled for operation next day, and I think the children find it encouraging to be together The interviews are informal but disciplined.

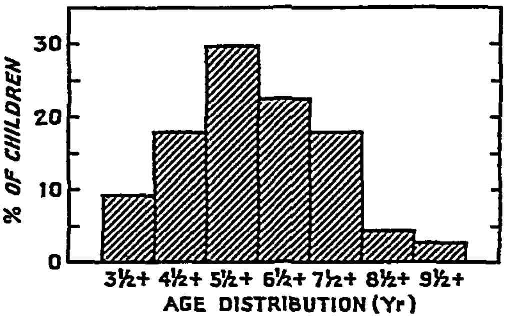

Fig 1—Age-distribution of the children studied

The children are asked whether they understand why they are in hospital, and then the preoperative ritual is explained, and, if necessary, demonstrated simply Questions are encouraged and answered. No promises of freedom from pain or discomfort are made Once explained, the procedure should be followed implicitly, for it is the unexpected that alarms most. The importance of a truthful explanation cannot be stressed too highly Most reasonable parents appreciate this, but through their own ignorance they may be unable to explain adequately

Premedication was by atropine gr 1/100 (0·6 mg) by hypodermic injection in the early part of the investigation, and by mouth in the later part.

Before operation the children were segregated in a side-room and then taken in turn to the nearby operating-theatre by the theatre porter Unnecessary people were kept out of the anæsthetic room, and face-masks were not worn.

Induction of Anæsthesia

Thiopentone sodium intravenously was used to induce anæsthesia in all cases but one (case 30) This technique has a particular advantage.

If a child's resolution breaks down during induction he can be calmed and reassured after venepuncture and before injecting thiopentone. In my experience, this has rarely been possible with a child who has become distressed in the initial stages of an inhalation induction.

During the induction of anæsthesia two observers attempted to classify the apprehensiveness of the patient into five grades Grades 1 and 2 were regarded as successful inductions, grades 4 and 5 as unsuccessful, and grade 3 as intermediate. Variations were recorded in these grades between the time the child entered the anæsthetic room and the establishment of anæsthesia

Maintenance of Anæsthesia

Anæsthesia for tonsil dissections was maintained with thiopentone intravenously followed by 60–70% nitrous oxide in oxygen through an endotracheal tube, which was passed nasally after suxamethonium had been given intravenously Small increments of the relaxant were repeated as necessary No other inhalation agent was used. When the tonsils were guillotined a single dose only of thiopentone was used (Hodges 1955)

After Operation

I make a point of talking with each child as soon as possible after consciousness is regained, and at least once before discharge from hospital, particularly if he has been upset by his experience. Much can be done by way of reassurance at this stage to make future encounters smooth.

The children were given a sedative after operation when necessary (usually an opiate derivative in small doses), and they were kept in bed for 24 hours They stayed in hospital for about 4 days, depending on the type of operation. The ward-sister was asked to make notes of any abnormal behaviour

Follow-up

A month after operation I saw the children as outpatients A questionnaire was sent to the parents of each child after 2–3 months and again after 2½ years With each questionnaire a covering explanatory letter was sent stating the object and

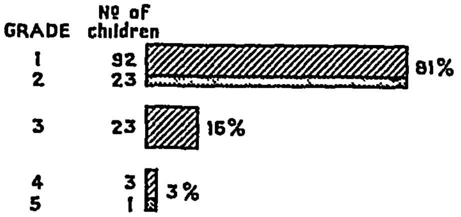

Fig 2—Grading of apprehension at the time of venepuncture

aims of the investigation. Finally the results of the first questionnaire were compared with those in a similar series of children who had had anæsthesia induced by inhalation, but who were treated comparably otherwise.

Results

Technique

In three of the hundred and forty-two children venepuncture was difficult, and in one (case 30) it was abandoned. No local complications arose from the intravenous injections.

Apprehension

The gradings at the time of venepuncture represent the greatest apprehension of the children during the period in the anæsthetic room (fig 2). Though many were successfully upgraded, no child became more apprehensive afterwards (fig 3). Only three times was a child precipitated from grade 1 to grade 3 by intravenous injection, and then not irretrievably.

These results correspond closely to the clinical impressions gained in many years' study of induction of anæsthesia intravenously.

In the initial clinical assessment of the whole series (table I), there is a suggestion that the younger children are more susceptible to psychic trauma as judged by their reactions during anæsthetic induction. 6% of children under $5^1/_2$ years, compared with 2% of children over this age, had an unsuccessful induction.

Postoperative Course

Immediately after recovery of consciousness I found the children neither difficult to manage nor resentful. No child was persistently distressed, and no abnormality nor behaviour change was obvious in hospital. This impression was confirmed in outpatients later. Only two children were obviously reluctant to return to hospital, one had been told by his parents when brought for admission that "he was NOT going to stay in", and the other, a 4-year-old, was very dependent on his mother.

Answers to Questionnaires

Detailed replies to the first questionnaire were received from the parents of a hundred and nineteen children—i e, 84% of the parents circularised. There seemed to be a higher proportion of replies from the group classified clinically as intermediate and failures, than from the more successful cases, but in all other respects there was no difference between the children of those parents who responded to the questionnaire and those who did not.

The replies to the questions are outlined in fig 4a analysed below.

Previous hospital experience.—Nineteen children had had some previous experience of hospital, but, according to the parents, only six (5%) were old enough at the time to appreciate it. Five children had previously had an anæsthetic—all as outpatients—and one of them (case 60) had had two.

TABLE I—CLINICAL ASSESSMENT OF 142 CHILDREN RELATING AGE TO STATE OF APPREHENSION

Age-group (yr)	$3^1/_2$	$4^1/_2$	$5^1/_2$	$6^1/_2$	$7^1/_2$	$8^1/_2$	$9^1/_2$	Total

	6%		2%					

Reasons given for hospital admission.—The reasons supplied by the parents to their children were classified as adequate, when a simple truthful explanation had been given, or inadequate, when the explanation might have led the child to expect something different from what was to happen. Explanations based on the necessity to cure some chronic symptom of which the child was quite aware, but without details of what would happen, were also considered adequate—e g, "to cure those coughs and earache". Obviously inadequate explanations included such fantasies as "like going to fairyland", or "like a holiday from school", and such deliberate deceptions as "the doctors are only going to look", or "you're not going to stay in". Explanations were also classified as inadequate when the treatment was allegedly to improve some vague condition in which the child had no interest or of which he might be unaware—e g, "to stop you snoring", or "because your tonsils are too big". Sometimes it was impossible to decide whether or not the explanation offered was adequate, but nine children (8%) had been given an obviously inadequate explanation.

What did your child think of his or her stay in hospital?—The parents of 75% of the children said that their child was contented and happy in hospital. Many children were enthusiastic, often using expressions such as "I enjoyed it" (forty-nine children), "I wish I could have stayed" (four children), or "it was very nice". 18% of the children expressed no adverse comment but had no particular liking for their experiences. Only 7% commented adversely. Two children were "not keen"—one because of homesickness. Two were "disappointed". Two were "rather unhappy"—one because of fear of smells and injections (case 30) and one because of homesickness. Two children who gave an unqualified "did not like it" were a 9-year-old delinquent boy and a wayward 8-year-old girl.

Comparison with previous experiences.—In the few cases where this question applied no significant information was gathered

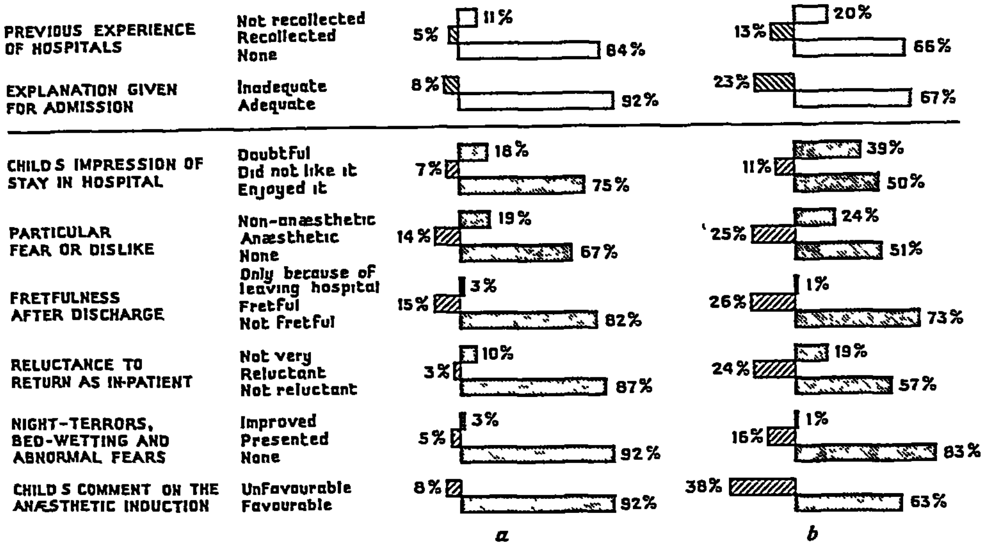

Fig 4—Replies to the questionnaires (*a*) anæsthesia induced intravenously, (*b*) anæsthesia induced by inhalation

Was there anything that the child particularly disliked or would be frightened of in the future?—Seventy-nine children (66%) had expressed no particular fear or dislike Forty children had dislikes, but in twenty-three they were not associated with the anæsthetic. These dislikes were minor and insignificant (mouthwashes, food, nightclothes, toys, cots) with the exception of two children who were homesick. Nineteen children had fears which could not be dissociated from anæsthesia Two were frightened of the hospital " atmosphere ", smells, equipment, &c. In case 60 this fear was related to the previous admissions to hospital, he was consequently only reluctant to return to the previous hospital Three other children were reluctant to return to hospital, and these together with twelve others (13%) " disliked " injections, but in only one child (case 30) did this amount to fear Seven were referring to their premedication hypodermic atropine and not to the intravenous injection. (Because in the early part of the investigation several children found the atropine injection was their most unpleasant experience, the premedication was later given by mouth.)

TABLE II—RESULTS OF SECOND QUESTIONNAIRE

Question	Answer	No of children
Does child talk of hospital now?	When reminded or asked	6
	Still mentions ' smells "	1*
	Only to comfort others	1
	Only lightheartedly	1
	Does not want to return	1
	Never mentions it	8
Was child permanently upset?	Not permanently	2
	Not at all	16
Did behaviour change persist?	No	17
	Recent tantrums	1
Has child been to hospital since?	No	16
	Yes	2
Did child go quite willingly?	Not applicable	16
	Yes	2

* This child was anæsthetised by an inhalation technique (case 30).

Was your child fretful after leaving hospital?—Three mothers replied, in effect, " only because he didn't want to come home " Eighteen others (15%) were fretful after leaving hospital, but in only one child (case 60) was this more than slight and transient

Would your child be reluctant to become an inpatient again, and why?—The parents of a hundred and four children (87%) said " no " dogmatically Twelve (10%) said " Not very, but " Three of these children had been homesick, one was fearful of the hospital " atmosphere ", and eight showed reluctance for unspecified reasons Only three children were extremely reluctant to return Two of these were below school age and homesick, and one (case 30) was frightened of needles

Behaviour changes—A hundred and four children showed no change in behaviour and in four children previous behaviour difficulties were improved. In eleven children changes of some sort appeared for the first time, or an established difficulty became worse Minor fears—e g , of smells and strangers—arose in five patients and severe night terrors in six (5%)

Did your child make any comment on how he or she was put to sleep for the operation?—A hundred and ten children (92%) made favourable or non-committal remarks—e g , " just a prick ", " it didn't hurt a bit ", " I didn't mind ", " it was wonderful ", &c. Of the five children who had previously had an anæsthetic three said that it was " better than the mask ", one (case 60) " did not like the smell " (a reply which may have been related to the previous experience), and the other said he would " rather have a balloon " The parents of nine children (8%) gave unfavourable replies, in eight cases because of the injection.

Other comments included a mixture of helpful suggestions, minor criticisms, and thanks, which were not strictly relevant to this paper

The replies to the second questionnaire were either entirely negative or were a recapitulation of the facts already known In none of the eleven patients had the previously reported behaviour change persisted The replies from the parents of these and eleven other children in whom at the final assessment there was reason to doubt the success of the technique are listed in table II)

Classification of Findings

The children can be divided into two groups In group 1 all psychic trauma had been avoided, but in group 2 it had not (see table III)

The children in group 1 showed no fretfulness nor behaviour changes after operation, and their parents thought they would submit willingly to a similar procedure Ninety-seven children (82%) fall into this category as judged by the results of the first questionnaire These included eighty-one of the ninety-five children in whom anæsthesia had been induced successfully on clinical grounds, thirteen of the twenty-one classified as intermediate, and all those classified as failures In none of the children with clinically successful inductions who ulti-

TABLE III—CLASSIFICATION OF 119 CASES FOLLOWED-UP FOR $2^1/_2$ YEARS AFTER OPERATION

Grade of state of apprehension at induction	1 and 2	3	4 and 5	Total
Group 1 (successful) No fretfulness, no behaviour change, would be willing to submit to similar procedure again	81	13	3	97
Group 2a (successful) Same as group 1, but fretful postoperatively	8	3		11
Group 2b (unsuccessful) Children with postoperative behaviour changes				
Minor	3	2		} 11
Major	3	3		
Total	95	21	3	119

mately showed psychic trauma could anæsthesia be incriminated Thus clinical assessment seems to be a fairly reliable though possibly pessimistic guide to the success of anæsthetic induction

Most of the children (eighty-eight) in group 1 made no adverse comment on the induction of anæsthesia, but nine confessed to a dislike of "needles" Seventy-seven admitted to no dislike or fear, but eighteen had a minor dislike of some sort which was not related to the anæsthetic, and one child mentioned homesickness

The general impression gained was that, far from being harmed, most of the children in group 1 had benefited from their stay in hospital The experience was of a maturing nature The parents said, for example, "it made her feel quite grown-up, and she loved helping the nurses" or "it was an enjoyable adventure, something to boast about" Even children who appear distressed when anæsthesia is induced, and who may show reluctance to return to hospital, have probably not undergone psychic trauma provided that they show no specific fear and no behaviour changes after operation

The children in group 2 are more difficult to assess In 27% of cases (compared with 8% throughout the whole series) the parents had given inadequate explanations of the reason for admission The second questionnaire was completed by 82% of the parents of these children (table II)

TABLE IV—THE PROBABLE CAUSE OF PSYCHIC TRAUMA IN CHILDREN WITH POSTOPERATIVE BEHAVIOUR CHANGES

Case no	Age (yr & mo)	Particular dislike	Reluctance to return	Induction comment	Behaviour change	Cause of psychic trauma
68	$7^{4}/_{12}$	+	+	?	Fear of smells	Hospital "atmosphere"
78	6		+		Fear of strangers	Maternal separation
119	$4^{1}/_{12}$		+		"	"
94	$7^{7}/_{12}$	+ (anæsthetic)			"	Anæsthetic
147*	$4^{9}/_{12}$		+ + +		" and smells	Parental deceit
85	$7^{1}/_{12}$	+	+		Night terrors	Maternal separation
76	$7^{1}/_{12}$	+	+		"	Inadequate parental preparation
43*	$5^{10}/_{12}$				"	Maternal separation
143	4	+	+		"	"
148	$4^{9}/_{12}$	+ (anæsthetic)			"	Anæsthetic
11	$6^{8}/_{12}$	+ (anæsthetic)	+	+	"	"

* *Did not reply to the second questionnaire*

Within group 2 the children can be divided into two categories Those in the first category may have had some shortlived minor upset (e g, homesickness, dislike of injections, or discontent) as signified by their transient fretfulness, but, as none of these children had any other behaviour change, their management can probably be regarded as successful In the second category the children all showed behaviour changes, and their management cannot be regarded as successful The psychic trauma which caused minor behaviour changes was attributable to the anæsthetic in only one case, but in two children with major behaviour changes anæsthesia was probably responsible (table IV)

TABLE V—RELATION OF AGE TO FINAL ASSESSMENT IN CASES WHICH WERE NOT CONVINCINGLY SUCCESSFUL

Age-group (yr)	$3^{1}/_{2}$+	$4^{1}/_{2}$+	$5^{1}/_{2}$+	$6^{1}/_{2}$+	$7^{1}/_{2}$+	$8^{1}/_{2}$+	$9^{1}/_{2}$+
No in final classification							
Group 2a	1	1	3	4	2		
Group 2b	2	2	3	2	2		
Percentage of each age-group	33%	13%	16%	17%	20%	0	0
	18%		15%				

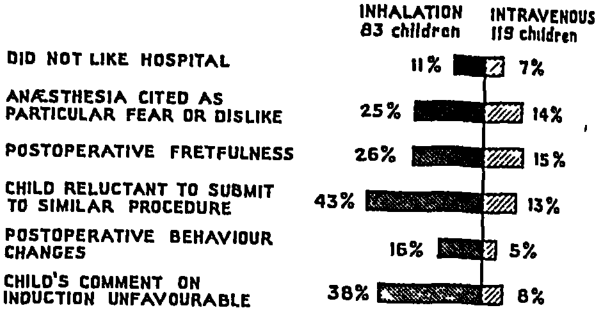

Fig 5—Comparison between sequelæ of anæsthesia induced by inhalation and by intravenous injection

Three patients (2%) in the whole series, therefore, could be regarded as showing psychic trauma due to anæsthesia At first it seemed that the younger children were more susceptible to psychic trauma (table I) But in the final assessment, taking all factors into consideration, age had less statistical significance than had been expected 18% of the children below $5^{1}/_{2}$ years and 15% of those above this age fell into group 2 (table V)

Finally, in an attempt to assess the value of intravenous induction of anæsthesia, the results of analysis of the first questionnaire were compared with those from the previous study in which the children were anæsthetised by open induction (fig 4*b*) The obvious and significant difference in the results (fig 5) is heavily in favour of those children in whom anæsthesia was induced intravenously

Conclusions

Of the hundred and forty-two children, most (84%) had not been in hospital before, but despite the anæsthetic and operation many (75%) were said to have enjoyed their stay Still more (87%) would submit, in the opinion of their parents, without protest to a similar procedure if it became necessary

The intravenous induction of anæsthesia in these children (without sedation) was technically successful in over 99% of cases, and only 3% were distressed during the induction period In only 2% could the anæsthetic be incriminated as a cause of behaviour changes

The results demonstrate clearly that psychic trauma is not an inherent part of anæsthesia and surgery, and that good results can be achieved without any drug premedication This series may be useful as a baseline for assessing premedicants given to children

In this series two factors seem to be mainly responsible for success—namely, the way the children were treated by everybody concerned and the method of inducing anæsthesia by giving thiopentone intravenously, which was neither frightening nor toxic

In children admitted to hospital factors other than anæsthesia may be more often responsible for psychic trauma Of the specific dislikes here encountered, 58% were not associated with the anæsthetic Homesickness was not uncommon among both the successful and unsuccessful cases Although it has always been accepted that the difficulties are greater in the very young, there was no significant correlation between age and success But children under 3 years should not be admitted to hospital for elective surgery if this can safely be postponed

Using this technique avoidance of psychic trauma depends not on the anæsthetist alone but on the whole team One person's lack of kindness and gentleness may utterly outweigh the highest degree of skill shown by any other

I should like to record my appreciation of the assistance and tolerance shown by my colleagues—anæsthetists and surgeons alike My thanks also go to the sisters and nurses, the theatre porters, and all concerned with the handling of these children, to the hundreds of parents who responded to the questionnaires, and to the thousands of children who directly and indirectly assisted me in this investigation

A PERSPEX ICTEROMETER FOR NEONATES

I H GOSSET
M.A , B M Oxon, M R C P
CONSULTANT PÆDIATRICIAN, NORTHAMPTON GENERAL HOSPITAL

THE icterometer is a simple device for estimating quickly the depth of jaundice in newborn babies at the cotside without taking a blood specimen The principle is to blanch the baby's skin by pressure, and match the resulting shade of yellow against a colour scale

The device is valuable as a means of (1) following the depth of jaundice in individual babies from day to day, and (2) indicating which babies ought to have their serum-bilirubin estimated

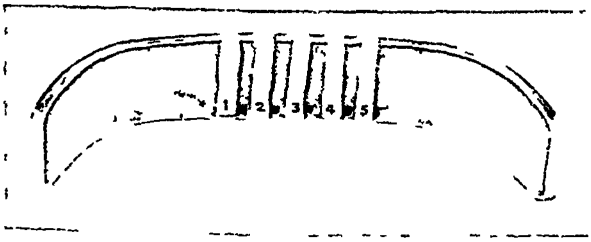

Fig 1—The icterometer

The icterometer (fig 1) is a strip of transparent perspex, $^1/_8$ in thick, $1^1/_4$ in wide, and 7 in long, curved at both ends for ease of handling On its convex surface are painted five transverse yellow stripes, in slightly different shades * These stripes and the spaces between them are $^3/_{16}$ in wide The stripes are numbered 1–5, the lightest in colour being 1, and the darkest 5

Method of Use

When the icterometer is used, the painted (convex) side is pressed against the tip of the baby's nose until the skin becomes blanched (fig 2) The yellow colour of the skin can then be matched with the yellow stripes on the scale The reading is recorded according to the number of the best match, or, if the colour falls half way between two stripes, as $1^1/_2$, &c

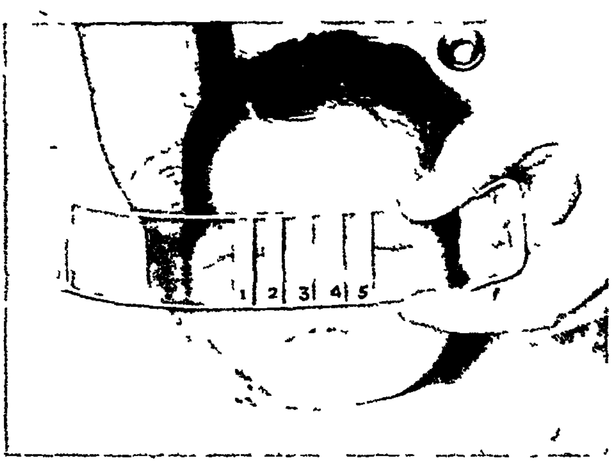

Fig 2—The icterometer in use

The nose is the obvious place for the test, because it is so easily accessible I have tried using other parts of the body but have found that readings were quite different

The instrument is washed with soap and water before being used on another baby Disinfectants or boiling could damage the perspex or discolour the yellow paint

The icterometer was originally devised in March, 1954, as a means of following the depth of jaundice in a baby from one day to the next In this it has been highly successful, for it shows at once whether the baby's skin is more or less jaundiced than it was the day before This is often all one wants to know It also enables the depth and duration of the jaundice to be permanently recorded, which may be invaluable later on

Correlation with Serum-bilirubin

In order to see how far the icterometer reading could be correlated with the serum-bilirubin level, a series of 229 comparative readings was made The results (fig 3) show broad agreement between the two methods, but the scatter is fairly wide, and one cannot deduce from a given icterometer reading what the serum-bilirubin level will be This is not surprising, because the series comprises many different babies, and the icterometer is influenced

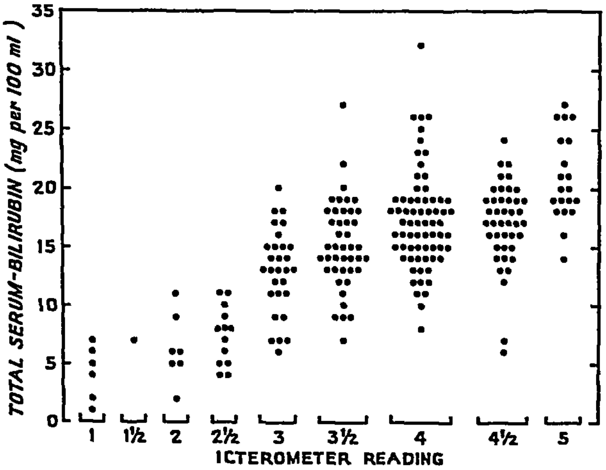

Fig 3—Icterometer readings compared with total serum-bilirubin levels (estimated by Molloy and Evelyn s method) Each dot indicates one reading

not only by jaundice but also by slight variations in skin colour between one baby and another

---

* These were of Robbialac Colorizer' paint no 501, shades A, B, C, D, and E made up in robbialac grey base undercoat

Fortunately one is much more concerned in practice with the interpretation of serial readings in single babies than with random sampling of the kind shown in fig. 3, and my experience has been that when serial observations are made on individual babies from day to day, the serum-bilirubin levels *and icterometer readings do in fact tend to rise and fall together*

A Screening Test

Recording the intensity of jaundice in premature babies during the first week of life is important because an exchange transfusion may be necessary to prevent kernicterus Because the depth of jaundice cannot be judged by simple inspection, a great many babies are subjected to serum-bilirubin estimations to make sure of detecting the few at risk By using the icterometer as a preliminary screening test, some of these serum-bilirubin estimations can be avoided

At Northampton General Hospital we take 24 mg per 100 ml of total bilirubin (using the method of Molloy and Evelyn) as our threshold for replacement transfusion It follows that an accurate laboratory estimation of the serum-bilirubin is needed as soon as a level of about 20 mg. per 100 ml. is exceeded But fig 3 shows that in comparative tests no serum-bilirubin levels over 20 mg per 100 ml were encountered in babies with icterometer readings of 3 or less. We have therefore made it our practice for the past 2½ years not to ask for serum-bilirubin estimations until the icterometer reading is 3½ or over, and we have no reason to believe that we have missed a case of kernicterus

Disadvantages

The icterometer is so simple that there are obvious snags

(1) The yellow stripes do not always give a perfect match with the baby's skin, but in practice this does not seem to matter, because different observers get closely comparable results

(2) It may not be reliable in artificial light

(3) It cannot be used for babies with bruised noses (e g, following face presentation)

(4) Its use is limited in black-skinned or yellow-skinned babies, in whom it will merely show whether or not the jaundice *is increasing from day to day A Siamese baby, for example,* had at birth an icterometer reading of 3, which rose gradually during the next few days to 5, and then fell back again to 3 and stayed there This enabled us to spot her jaundice, and to say when it had passed its peak, but we had to invoke the laboratory to determine the extent of jaundice, because our scale was not calibrated for Siamese babies

(5) Milia on a baby's nose are a nuisance, but do not prevent the use of the icterometer

(6) When neonatal jaundice develops rapidly (as in blood-group incompatibility) the serum-bilirubin can rise so fast that the skin colour lags behind Hence babies developing jaundice within 36 hours of birth should always have their serum-bilirubin estimated, for in these circumstances it would be dangerous to rely on the icterometer as a screening test

(7) Cross-infection is an obvious possibility, but after more than 4 years the icterometer has not yet been incriminated The risk could be reduced by having a separate icterometer for each baby

(8) All the icterometers that I have used so far have been painted from five tins of robbialac paint made up in 1954 The colour shades of icterometers made from different batches of paint may not be identical with those I have described in this paper, although the makers of robbialac claim that their colorizer paints are standardised The same general principles will apply, however, and the colour differences are unlikely to interfere with the usefulness of the icterometer as a rapid cotside test

My thanks are due to the staff of the premature unit in the Barratt Maternity Home for testing and using the icterometer, to Dr D Phillpott and his laboratory technicians for their cooperation in *calibrating it against the serum-bilirubin, to Mr J Pamely for fig 1, and to Dr. W J A Hall Turner for his help in collecting the* data for fig 3

Icterometers are now manufactured (using the original tins of paint) by Thos A Ingram & Co, Ltd, Santon Works, Prescott Street, Birmingham, 18, at a cost of 9*s* 6*d* each for quantities of a dozen For larger quantities the price will be lower

CLINICAL ASSESSMENT OF DEPTH OF JAUNDICE IN NEWBORN INFANTS

P E Culley
M B Manc
RESEARCH ASSISTANT, BIRMINGHAM MATERNITY HOSPITAL

J A H Waterhouse
M A Cantab, Ph D Birm
READER IN MEDICAL STATISTICS, UNIVERSITY OF BIRMINGHAM

B S. B Wood
D M Oxon, M R C P, D C H
CONSULTANT PÆDIATRICIAN TO THE UNITED BIRMINGHAM HOSPITALS

Kernicterus, the most important complication of neonatal jaundice, has three main causes

(1) Rhesus incompatibility, where, because maternal blood tests in pregnancy and the cord-blood findings at birth give reliable forewarnings, appropriate early exchange-transfusion can be undertaken

(2) ABO incompatibility, where Tovey et al. (1959) found that the only important guides to treatment are the appearance of early jaundice and the frequent estimation of serum-bilirubin *(to measure its approach to the potentially toxic level of 25 mg* per 100 ml)

(3) Immaturity, the jaundice of which appears later but which requires the same control as that of ABO incompatibility (Crosse et al 1958)

Odell (1959) has suggested that kernicterus may depend upon the diffusibility of bilirubin, and that this may be determined by its degree of coupling with plasma-albumin, he further postulates that this may explain the occasional case of kernicterus at low serum-bilirubin levels

The relation of skin colour and serum-bilirubin has been the subject of discussion for many years

Davidson et al (1941) pressed a transparent tongue-depressor on the baby's skin and showed a qualitative relation between the degree of jaundice and the bilirubin level Allen (1958) described the value of polished lucite in the early detection of jaundice, although Lathe et al (1958) pointed out occasional high serum-bilirubin levels without apparent skin change It is well known that as jaundice fades the skin colour lags behind the serum-bilirubin level

A simple instrument, the icterometer, has been devised by Gosset (1960) to estimate the degree of skin icterus We have used this in an attempt to determine whether skin colour bears any relation to serum-bilirubin levels We set out to assess the value of this method as a screening test in neonatal jaundice, and, in view of the important observation of Davidson et al (1941) that one baby had a serum-bilirubin level of 12 1 mg without showing clinical jaundice, to assess the chances of missing a dangerously high level

ICTEROMETER READINGS CORRESPONDING WITH INDIRECT SERUM-BILIRUBIN LEVELS

Icterometer reading	No of observations	Serum-bilirubin (mg per 100 ml., indirect)		
		Mean	S.D	Range
2	4	5·55	1·61	3·9
2½	29	7·57	2 27	11 7
3	38	10·03	2 26	10·1
3½	65	12 31	2·50	12 3
4	27	15 73	3·03	11 7
4½	19	19·06	3·62	13 8

Method

Between December, 1958, and June, 1959, inclusive, there were 998 live births in the Birmingham Maternity Hospital Of these, 669 babies who remained in hospital for six days or more were available for synchronous icterometer and bilirubin estimations 165 babies were jaundiced, 59 being premature, and a total of 183 observations were made. Those babies with fading jaundice, and those who had recently had exchange transfusions were excluded Towards the end of the study only those showing icterometer readings over 3 were included. Icterometer readings observed by one, two, or three of us never varied by more than a half reading Blood was taken by venepuncture, or occasionally by heel prick, and bilirubin was estimated by the method of Lathe and Ruthven (1958) The differences between venous and heel-prick blood were not regarded as important in this correlation.

Results

The icterometer readings corresponding with the indirect bilirubin levels are shown in the table together with the mean, the standard deviation, and the range The relation between icterometer readings and the mean indirect bilirubin level is shown in fig 1

From these data fig 2 has been prepared to show the proportion of cases at or above a given bilirubin level that would be missed by taking a selected icterometer reading as a criterion

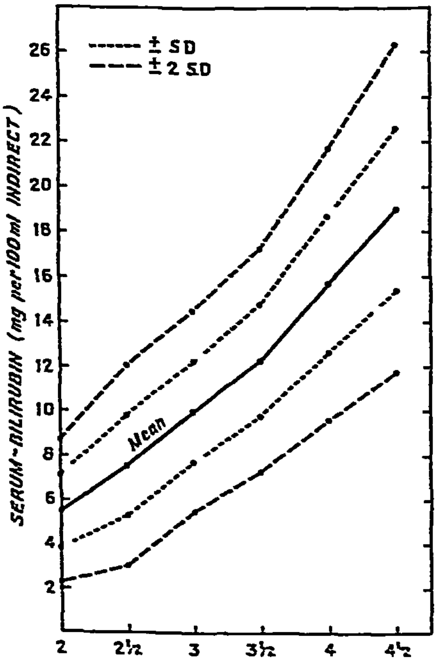

Fig 1—Relation between icterometer readings and the mean indirect bilirubin level.

Curves are drawn for three adjacent icterometer readings within the critical region, and they are related to indirect bilirubin levels Thus, for example, taking an icterometer reading of 3, only 1% of cases with an indirect level of 16 mg per 100 ml. or more will be missed.

Discussion

This simple instrument, which can be carried in the pocket and washed after use as one washes one's hands, seems to have a place in the nursery for the newborn Hitherto the timing of bilirubin estimations has depended on the unaided eye of the clinician, but this new instrument provides both a direct colour match and a means of expressing the blood, with the resultant pink colour, from the superficial skin layers Odell (1959) points out that measurement of the serum-bilirubin itself by present methods gives no indication of the degree of saturation of the serum-proteins with bilirubin, possibly, as a measure of diffusible bilirubin and the risk of kernicterus, the degree of skin pigmentation may be as good or even better

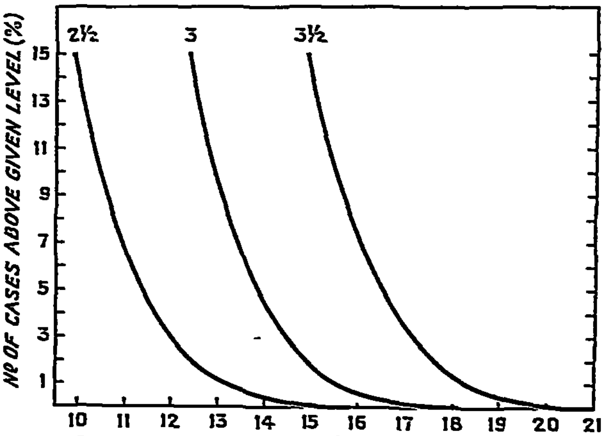

Fig 2—Proportion of cases above a given bilirubin level that would be missed by using the icterometer

For practical purposes our work suggests that, in cases other than those with rapidly increasing jaundice in the first twenty-four hours of life (such as in rhesus incompatibility), if the icterometer reading is 3 or below serum levels can be omitted, whereas above this reading blood studies should be undertaken Our observations were made in daylight, but artificial daylight lamps seem to give comparable results at night, and would be useful in a neonatal department

We are very grateful to Dr Dorothy Barrow for help with the clinical side of this work, and to Mr W F Johnson and Miss J M. Reynolds for performing most of the bilirubin estimations One of us (P E. C.) was in receipt of a grant from the United Birmingham Hospitals endowment fund.

THE posterior-chamber acrylic * lens was described by Harold Ridley (1951) and the anterior-chamber implant by Strampelli (1954) Since the Strampelli type of lens was introduced into this country in 1956 it has been used to treat many hundreds of patients, and it is now recognised as a useful aid where uniocular aphakia cannot be corrected by a contact lens (*Lancet* 1958)

Eye injuries are not uncommon in childhood and when they result in uniocular cataract or aphakia the problem is urgent Amblyopia ex anopsia will probably complicate the picture within six to twelve months of the injury and is usually irreversible Very few of these young patients can be fitted with contact lenses within this period and the anterior-chamber implant offers the only opportunity of restoring reasonable visual acuity and binocular function

Some months ago I reported a series of 100 cases (Choyce 1959) In a second 100 I have used an implant differing in a number of respects from that originally designed by Strampelli The two most important differences are

1 Flattening of the anterior radius of curvature from 12 to 14 mm
2 Reduction of the thickness of the haptic portion from 0 91 to 0 50 mm

With this new thin implant the incidence of serious complications, such as endothelial corneal dystrophy, has been much lower These wholly transparent implants can also be used to treat, with success, cases of uniocular high myopia in young persons, but the climate of opinion in this country is against their use to correct binocular myopia or hypermetropia, because this can be adequately corrected by spectacles or by contact lenses

Obviously it would be an advantage if either the haptic or the optic portion of these implants could be made opaque, while the other portion remained clear The problem is how to tint or colour the polymethyl methacrylate of which they are composed

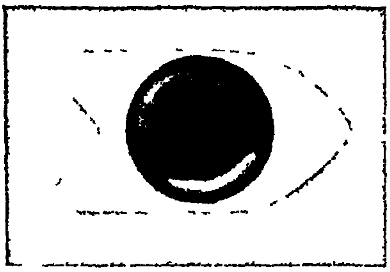

Fig 1—Anterior-chamber all-acrylic implant with transparent haptic and black optic the occlusive implant

Black perspex is readily made by introducing carbon-black, and it can be thermally fused with transparent perspex so that one can make an implant with a clear haptic and a black optic, or vice versa The result is a homogeneous piece of perspex (fig 1) which has the same mechanical properties as an ordinary implant and therefore will not break into its black and transparent portions after introduction into the eye

The implant with a black optic and a transparent haptic can be used to relieve intractable diplopia as in the following case

A patient with a severe anxiety state was referred by the psychiatrist because of diplopia Caused by a head injury in his teens, this remained constant and disabling despite numerous operations on the eye muscles The conventional shade over the squinting eye afforded no relief

Insertion of this occlusive implant relieved his diplopia and also his anxiety state For the first time in many years he is usefully employed and leading a contented home life If later he should need to make use of the sight in this eye, the implant can be removed

This type of implant can also be used to improve the appearance of a blind eye with an ugly complicated cataract such as is often seen after longstanding retinal detachment

The reverse of this type of implant—i e, with black haptic portion and a clear central optic—could be used in many cases where the iris is absent or deficient, but the large black pupil which would result would be very unsightly Imperial Chemical Industries were therefore asked to find some way of colouring the polymethyl methacrylate with pigments which would not diffuse into the eye and irritate it They have produced a partial answer in the form of perspex in three shades of blue and one shade of dark brown which (like black perspex) can be thermally fused with a clear central optic At the moment, matching a green iris is rather unsatisfactory Experience shows that, when inserted into the anterior chamber of a patient with a green or tawny iris, a brown haptic portion looks better than any of the blues

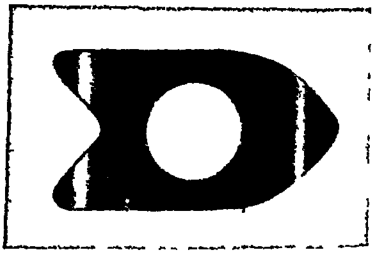

Fig 2—Anterior-chamber implant with coloured haptic and transparent optic for cases with iris deficiency

Thus the surgeon can introduce into the anterior chamber an implant which appears to fill in a coloboma of the iris with a haptic portion of appropriate hue If the coloboma is large, the diameter of the optic can be reduced to 2, 3, or 4 mm, thus sharpening the retinal image, as by the use of a stenopæic aperture (fig 2) If spherical ametropia is also present, a suitable correction can be moulded on the posterior surface of the central optical portion The following are examples of cases treated in this way

1 A youth of 16, with partial albinism, was also a low-grade myope Insertion of an implant, with brown haptic and a 4 mm optic with suitable myopic correction, has almost eliminated the photophobia from which he has always suffered The nystagmus is greatly reduced and the visual acuity, which was 6/60 with a myopic correction, is now 6/18

2 An engineer with a heavily pigmented brown iris sustained a perforating corneal wound with an iris prolapse, which resulted in a substantial temporal coloboma of the iris He suffered intense photophobia, not relieved by a tinted contact lens He had to wear a shade over this eye most of the time Insertion of an implant with a brown haptic has relieved the photophobia, and from a distance of a few feet the eye appears normal

3 A blue-eyed patient sustained a perforating wound in childhood which left him with a large iris coloboma above and temporally, and aphakia Before operation his corrected visual acuity was 6/60 After insertion of an implant with a dark-blue haptic and with an optical portion which corrected the aphakia, the photophobia has been eliminated and the visual acuity is 6/18

---

* Acrylic = polymethyl methacrylate or 'Perspex'

Congenital aniridia seems to offer another promising field for the use of this type of implant

I am indebted to Mr P M. Caudell of the instrument department of Rayner Ltd., and to the plastics division of Imperial Chemical Industries, fo- their collaboration in the development of these new implants

REDUCTION OF SPUTUM VISCOSITY BY A WATER AEROSOL IN CHRONIC BRONCHITIS

K N V PALMER
M.A., M.D Cantab, M.R.C.P
SENIOR LECTURER IN MEDICINE IN THE UNIVERSITY OF ABERDEEN

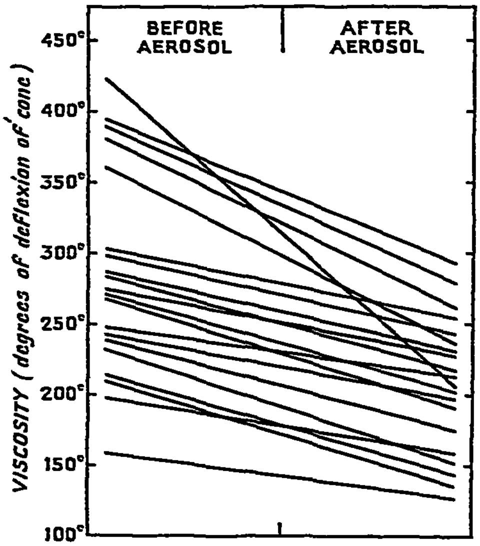
SPUTUM in chronic bronchitis is of two main kinds "mucoid", which is clear, gelatinous, and viscid, and "purulent", which is yellow, opaque, and less viscid Although purulence of sputum is shortlived when suitable antibiotics are used, mucoid sputum is not reduced by chemotherapy (May 1953), and persistent viscid mucoid sputum is an important manifestation of chronic bronchitis (Oswald 1954) Mucoid sputum is a mucoprotein gel, its viscosity depending on its mucoprotein content and the degree of hydration of the gel To reduce the viscosity of mucoid sputum, aerosol inhalation of enzymes and detergent solutions has been used (*British Medical Journal* 1954) Good results have been reported with solutions of trypsin (Unger and Unger 1953, Harwood Stevenson and Kinmer Wilson 1957), but others have thought it too irritant and have not been impressed by its mucolytic action in vivo (Farber et al 1954, Forbes and Wise 1957) Recently a less irritant derivative of trypsin—chymotrypsin—has been used by insufflation of the dry powder into the bronchial tree, with promising results (Robinson et al 1958)

The aerosol detergent used most often has been 'Alevaire' (which is a solution of a detergent with sodium bicarbonate and glycerin), and symptomatic benefit has followed its use, but a control solution containing water and sodium bicarbonate without detergent has been shown to facilitate expectoration as effectively as alevaire. Moreover, an hour's aerosol inhalation with either alevaire, the control solution, normal saline solution or water is followed by a reduction in sputum viscosity of approximately equal degree (Palmer 1957) This suggests that these solutions owe their effect to their water content. I have, therefore, measured the effect of the aerosol inhalation of water on the viscosity of mucoid sputum in chronic bronchitics

Method

Twenty inpatient chronic bronchitics were admitted to the trial. Measurements were made in the afternoon because, in a period of control observation, the viscosity of the sputum was found to be most constant at this time.

Each patient was studied for three hours In the first hour sputum was collected in a dry container and its viscosity measured (vide infra) In the second hour about 15 ml. of water was nebulised in a 'Collinson' or 'Oxygenaire' apparatus by oxygen. In this way the water is administered as a fine "dry" mist with a particle size of 0 5–3 0μ. Sputum produced for one hour after the inhalation was collected and its viscosity measured. Patients were asked whether expectoration was easier after the inhalation, and improvement in rhonchi was noted.



Effect of water aerosol on viscosity of sputum.

Viscosity was measured in a cone and plate viscometer which was specially designed for this purpose (Palmer 1957) Viscosity is expressed in degrees of rotation of the cone—the deflection increasing with greater viscosity

Results

The results (see figure) show that there was a reduction in sputum viscosity in all twenty patients after the aerosol inhalation of the water mist for one hour, and that generally this was greatest where the initial viscosity was highest. The mean reduction in viscosity was 71 4° (21 5%) (range 221–23°) All the patients felt that coughing was easier afterwards, and notable reduction in rhonchi was observed in many

Comment

An hour's aerosol inhalation of water reduced viscosity and greatly assisted expectoration in chronic bronchitics with viscid mucoid sputum Reduction in viscosity was greatest in those with the most viscid sputum, probably because the mucoprotein gel takes up water most avidly in this type of secretion

This treatment is non-irritant, is devoid of toxic effects, and is physiological in action In this trial oxygen was used to aerolyse the water In patients with chronic bronchitis and emphysema and incipient respiratory failure (carbon-dioxide narcosis) continuous oxygen for an hour may be contraindicated (Westlake et al. 1955) For these patients the water may be aerolysed by compressed air, or compressed air alternated with oxygen

Summary

In twenty chronic bronchitics with mucoid sputum, aerosol inhalation of a water mist for an hour reduced sputum viscosity and made expectoration easier

AUTOIMMUNE HÆMOLYTIC ANÆMIA TREATED WITH VENOM ANTISERUM

INDER SINGH
M.B. Rangoon, F.R.C.P.E., F.R.F.P.S.
PROFESSOR OF MEDICINE

G. W. G. BIRD
M.B. Madras, Ph.D. Lond.
OFFICER-IN-CHARGE, BLOOD-TRANSFUSION DEPARTMENT

ARMED FORCES MEDICAL COLLEGE, POONA, INDIA

VENOM antiserum ('Antivenene') is concentrated polyvalent anti-snake-venom serum, prepared at Haffkine Institute, Bombay, against the venoms of the four common poisonous snakes of India—i.e., cobra, common krait, Russell's viper, and saw-scaled viper. When injected intravenously with the venom into white mice each millilitre of the serum neutralises not less than the following quantities of dried venom: cobra 0.6 mg., common krait 0.45 mg., Russell's viper 0.6 mg., and saw-scaled viper 0.45 mg. If venom antiserum is given intravenously or intramuscularly the antibody in autoimmune hæmolytic anæmia is quickly removed, the antiglobulin test becomes negative, and hæmolysis ceases speedily.

Material and Methods

Venom antiserum was given to twenty-seven patients, comprising twenty-two men and five women. Their ages ranged from 19 to 32 years, and the duration of anæmia was from 3 weeks to 2 years. Twelve gave a past history of malaria 3–7 years previously, and seven had evidence of ankylostome infection, but antimalarial therapy and disinfestation before treatment with venom antiserum had not altered the course of the disease. Two women were in mid-pregnancy. Twenty-one patients were seen between the cold months of October and March. Four cases were acute, and the other twenty-three were chronic.

A clinical as well as a serological remission, as in case 26 (vide infra), was desired. Venom antiserum was effective by both the intravenous and the intramuscular route, but the intravenous route was used for treating severe cases only. It usually sufficed to inject 20 ml. of concentrated venom antiserum intravenously and 20 ml. intragluteally, the intramuscular injection being repeated on the 3rd, 7th, and 14th days of treatment. In very severe cases an additional intravenous injection was required on the 3rd day for complete clinical and serological remission. In mild cases 20 ml. of concentrated venom antiserum injected intragluteally on the 1st and 14th days was usually enough. But sometimes complete serological remission was not obtained with this dose, as in case 11 (vide infra), and we now think an additional dose of 20 ml. on the 3rd day is advisable.

Results

The mild cases showed no further hæmolysis after the first injection of venom antiserum, and the blood-picture improved steadily.

The severe cases showed a dramatic remission in constitutional symptoms within 48 hours of the first intravenous and intramuscular injections of venom antiserum, and the patient was well on the way to recovery within a week.

During follow-up for 5–26 months there were no clinical failures.

Mode of Action

Venom antiserum was first used in the treatment of autoimmune hæmolytic anæmia because it prevented hæmolysis in blackwater fever (Singh and Singh 1944). Although it has always been effective in autoimmune hæmolytic anæmia so far, the mechanism by which it prevents hæmolysis is not yet absolutely clear. The serological results in the following cases indicate that venom antiserum rapidly "removes" the antibody and potentiates in vivo an unknown protective mechanism.

Case 26 (blood-group B) had a powerful, apparently non-specific, agglutinin acting at the following titres:

	37°C	*4°C*
Own cells	*512*	*8192*
Other cells	64	2048

The direct Coombs' test was positive. No separable components for O, A_1, or B cells were present, the specificity of the autoagglutinin was unknown.

5 days later, after a course of amodiaquine ('Camoquin'), which had been administered for suspected malaria, the antibody concentration was not significantly different, and the direct Coombs' test was still positive. But 2 days after venom antiserum was given the antibody titre dropped appreciably:

	37°C	*4°C*
Own cells	0	64
Other cells	0	16

and the direct Coombs' test was negative.

Inhibition tests were made in vitro using the original sample of the patient's serum. An ampoule of dried venom antiserum was reconstituted with 10 ml. distilled water. This solution was diluted 150 times to attain a concentration corresponding roughly to the serum level immediately after the intravenous injection of venom antiserum, and to inactivate agglutinins for human erythrocytes in the reconstituted venom antiserum. Equal volumes of diluted venom antiserum and the patient's serum were mixed, left at room temperature for 30 minutes, and then tested against various erythrocytes; there was no inhibition of agglutination.

Thus the therapeutic response to venom antiserum cannot be attributed to the direct inhibition of the autoagglutinin.

Case 11.—The antibodies in the serum of this patient have already been described (Bird 1951). After a 2-week course of venom antiserum, given as for a mild case, her autoantibodies became active only at low temperatures. 6 months later they were active against her own cells at 37°C, but she showed no signs of overt or masked hæmolytic anæmia, and the direct Coombs' test was negative. Some in-vivo protective mechanism, therefore, seemed to be at work.

We are grateful to Lieut.-General B. Chaudhuri, Director-General, Armed Forces Medical Services, India, for permission to publish this report.

"... if someone were to plead the virtues of an intellectually pastoral existence, not merely quiet but acquiescent, and with no more than a pensive regret for not understanding what could have been understood, then I believe I could listen to his arguments and, if they were good ones, might even be convinced. But if he were to say that this course of action or inaction was the life that was authorised by Nature, that this was the life Nature provided for and intended us to lead, then I should tell him that he had no proper conception of Nature. People who brandish naturalistic principles at us are usually up to mischief. Think only of what we have suffered from a belief in the existence and overriding authority of a fighting instinct, from the doctrines of racial superiority and the metaphysics of blood and soil, from the belief that warfare between men or classes of men or nations represents a fulfilment of historical laws. These are all excuses of one kind or another, and pretty thin excuses. The inference we can draw from an analytical study of the differences between ourselves and other animals is surely this, that the bells which toll for mankind are—most of them, anyway—like the bells on alpine cattle; they are attached to our own necks, and it must be our fault if they do not make a cheerful and harmonious sound."—Prof. P. B. MEDAWAR, *Listener*, Dec. 24, 1959, p. 1118.

THE LANCET

LONDON 9 JANUARY 1960

Poliomyelitis Vaccines

Killed poliomyelitis vaccine can prevent paralytic poliomyelitis: this was demonstrated in a statistically sound controlled trial in the U.S.A.,[1] and subsequently confirmed in this country by a similar trial.[2] These trials showed that a primary course of vaccine was about 70% effective in preventing paralytic poliomyelitis (this means that the attack-rate in the vaccinated was 30% of that in the unvaccinated). There were, therefore, high hopes that poliomyelitis would dwindle into clinical and epidemiological insignificance, although many authorities still believed that the final answer might be an attenuated vaccine—mainly because of doubts about the duration of immunity conferred by killed vaccine. A living vaccine is thought likely to give a durable immunity because of the finding of Paul et al.[3] that poliovirus antibodies apparently persisted for forty years in an isolated Eskimo population, and a living vaccine has been favoured because yellow fever and smallpox are successfully controlled in this way (though the immunity after smallpox vaccination is not lifelong). On the other hand, poliovirus neutralising antibodies fall in titre during convalescence at very much the same rate as they decay in people vaccinated with killed or attenuated virus,[4–6] so the superiority of living vaccine in this respect cannot be taken for granted.

Unfortunately, despite the widespread use of killed vaccine, there have been several substantial outbreaks of poliomyelitis, especially in the U.S.A.: in 1959 there were almost certainly as many paralytic cases in the U.S.A. as there were in 1956. This situation has led to disquiet lest the vaccine should be proving less effective than was to be expected from the Francis report,[1] and it has also stimulated intense interest in attenuated-virus vaccines. Soon after the Francis report appeared, the Cutter disaster led to changes in manufacturing and safety-testing requirements for killed vaccine. It is clear that these changes produced a safe product—but was potency sacrificed? There is some evidence that the antigenic potency of American vaccines has declined: for example, Salk[7] has found, in a survey of children in Pittsburgh, that the antibody response in 1956 was much superior to that in 1958. Similarly, other workers in the U.S.A. have reported very low levels of antibody response in children. In Barr's experience[8] more than 50% lacked antibodies to type-1 and type-3 virus after three doses. Fox et al.[9] recorded similar experiences and also found that Salk vaccination did not appear to prevent natural infection of the alimentary canal with polioviruses, whereas naturally acquired antibodies did prevent infection. This difference is probably due to differences in circulating antibody titre, but it has been suggested that a local alimentary immunity conferred by natural and attenuated virus infection is responsible.[10] The vaccine used in the Medical Research Council trials in this country, which assessed both antigenic potency and effectiveness in preventing paralysis, was made with material that had passed the more stringent control tests introduced in this country after the events in America. The impression that killed vaccine may be less effective than had been expected was to some extent supported by preliminary data published by the U.S. Communicable Diseases Center in poliomyelitis surveillance reports, which showed substantial numbers of cases in individuals given three doses of vaccine. Recently, however, a new report[11] gives reassuring preliminary figures of vaccine effectiveness. From census figures and an extensive sample survey of immunisation status, age-specific attack-rates for unvaccinated and vaccinated individuals were calculated. From these figures the effectiveness of the vaccine can be estimated. In 1958 and the first 45 weeks of 1959 for age-groups up to 14 the estimates exceed 90% against paralytic poliomyelitis for those given three or more doses of vaccine. It must be emphasised that the results are preliminary, especially those for 1959. Two important confusing factors are present: for 1959 the diagnosis of paralytic poliomyelitis has been accepted although revision of the diagnosis in some cases is probable at the 60-day follow-up report, and there is considerable heterogeneity in the immunisation status of the population. Thus, a protection-rate calculated on the basis of the overall national immunisation-rate may overemphasise the protective effect of vaccine for poorly vaccinated population subgroups. Similarly, both the national immunisation surveys were carried out in September, which may boost the apparent effectiveness, since unvaccinated people who succumb early in the year would count in the unvaccinated attack-rate, yet those who escaped paralysis in an early epidemic and were subsequently vaccinated would be counted as vaccination successes. The effect of errors of diagnosis would be mainly to include cases presenting with paralysis which were not due to poliovirus. This source of error might, therefore, to some extent counterbalance the effect of different vaccination-rates. It is probable, however, that some cases of apparently non-paralytic poliomyelitis would have to be added to the paralytic group after follow-up. There is some evidence that the viruses isolated from both paralytic and non-paralytic cases are less likely to be poliovirus (and more likely to be other enteroviruses) in vaccinated than in unvaccinated people. Lennette et al.[12] report that poliovirus was isolated from 81% of unvaccinated patients with paralytic poliomyelitis under 5 years of age and other enteroviruses from 2%, whereas the isolation-rate was 36% for polioviruses and 21% for enteroviruses in infants who had had two or more doses of vaccine

[12] Lennette, E H Magoffin R L, Schmidt, N J, Hollister, A C, Jr *J Amer med Ass* 1959, 171, 1456

Although the exact figure of effectiveness may be subject to revision, it is unlikely that it will prove seriously wrong since it is confirmed in a preliminary study of a major outbreak in Des Moines The estimates of vaccine effectiveness exceed 85% for three doses for 3 separate population groups (Negroes and lower and middle socio-economic white groups), based on immunisation surveys early in the epidemic The mere concentration of cases in the least vaccinated groups—for example, the majority of cases were in the 0–4 year age-group and in Negroes (in the whole U S the rate for Negroes is twice that in whites and in localised epidemics is up to 15-fold higher)—provides prima-facie evidence of high vaccine effectiveness

It seems, therefore, that there are good grounds for believing that the killed vaccine has proved highly effective, but that immunisation programmes have proved less so Some of the proponents of attenuated vaccine have argued that the capacity of these attenuated strains to spread in the community and therefore to vaccinate involuntarily some of those reluctant to accept parenteral vaccine might be a positive advantage Moreover, they point out that killed vaccine has failed to halt the progress of several outbreaks,[13] and they contend that attenuated vaccine may well be effective under these conditions, not only by producing antibodies more rapidly but also by producing interference in the alimentary tract before active immunity is acquired Indeed, it has been suggested that epidemics may end not by exhaustion of susceptibles but by the emergence of attenuated viruses All this is, for the moment, supposition The best way of combating an epidemic of poliomyelitis is probably the method of passive and active immunisation found so successful for diphtheria [14] It is known that gamma-globulin is effective in preventing poliomyelitis [15], indeed, when used for treatment, gamma-globulin of very high titre has mitigated the severity of experimental poliomyelitis in monkeys [16] Combined gamma-globulin and poliovaccine, perhaps in larger doses,[17] should therefore prove effective

Recently MELNICK and his colleagues [18] examined some of the candidate strains for inclusion in attenuated vaccine They found both Sabin and Lederle strains to be more virulent than expected They also found evidence that Sabin strains (which were the most attenuated) could undergo mutation to substantially greater virulence during passage in man The difficulties of conducting an adequate trial of safety when virulent virus causes only 1 clinical case in 100–500 infections are considerable There are also formidable technical difficulties of manufacture to face in order to establish consistently safe vaccine when the virus is mutable and the tissue used to cultivate it is potentially contaminated with numerous viruses [19] These viruses, except virus B, which is a fatal human pathogen, are of unknown effect in man The remarkable properties of the newly discovered S E polyoma [20] virus should perhaps be a warning against dismissing these viruses from consideration as human pathogens In view of these manufacturing and testing difficulties, the great economies which it was hoped might follow from the use of living vaccine may prove illusory, but the difficulties have been no deterrent to the mass programme already completed, particularly in Russia and Eastern Europe In Russia, where Sabin strains have been used, over 10 million people have received all three types of virus, and neither here nor elsewhere has there been any suggestion that poliomyelitis has been caused by any of the strains of attenuated virus The attenuated vaccine will probably prove effective provided there is not too much interference with the establishment of the poliovirus infection by other enteroviruses, as has been noted, for example, by HORSTMANN et al [21] MELNICK et al , however, plead for caution in the development of attenuated vaccines The introduction of killed vaccine required caution, and yet disaster was not wholly avoided greater caution is called for in introducing a vaccine known to be able to spread uncontrollably in the community And the need for care is further underlined by the apparently reassuring figures of the efficacy of killed vaccine It may be that killed vaccine can be made more widely acceptable by the use of combined antigens, which are being effectively given in Canada [22], and this would also have advantages in reducing the number of injections—a change that would be attractive to children, mothers, doctors, and the Chancellor of the Exchequer

Breech Presentation and Delivery

UNDER the most favourable circumstances fœtal loss associated with breech delivery is very low COX [23-25] has shown that at the Liverpool maternity hospital the fœtal mortality in uncomplicated cases has fallen steadily until now several resident obstetricians from that hospital can claim large personal series of deliveries with a fœtal loss below 1 5% These excellent results come from a teaching hospital which has long taken great interest in the management of breech delivery It is encouraging to learn from DALEY and MICHAEL [26] and HAY [27] that in non-teaching hospitals, even where breech deliveries are carried out by different people over the years, equally good results are attainable To some extent such results reflect a tradition passed from one generation of resident staff to another, but much of the credit must lie with the senior consultant staff who are ultimately responsible for standards It would be unrealistic to claim that hospital management of breech delivery is generally associated with such good results,

but the available evidence suggests that confinement in hospital is safer than at home Cox,[23] in his account of breech delivery in Liverpool in 1933–49, reported a fœtal mortality of 20% among 120 cases of uncomplicated breech delivery carried out by midwives in the patients' homes this despite the fact that the midwives were well trained in the Liverpool technique of delivery It is impossible for anyone, single-handed, in domiciliary surroundings to compete with the results obtained by a team in a hospital labour ward Nevertheless, some doctors and midwives still consider that a multiparous breech delivery can safely be conducted at home This is a dangerous belief, for there is good evidence [23 26 28–30] that the risk to the fœtus is greater in multiparous than in primiparous breech delivery

In order to assess fœtal mortality associated with breech delivery, Cox and others have excluded from their final figures cases complicated by such factors as placenta prævia, twin pregnancy, prematurity, and prolapse of the cord Although this arrangement is helpful, not all workers agree about which cases should be considered "complicated" and therefore excluded some maintain that prolapse of the cord, contracted pelvis, or long labour should be regarded as part of the intrinsic risk to the fœtus The Royal College of Obstetricians and Gynæcologists [31] gave some guidance on this point in 1948, but there is need for further clarification

Opinion remains divided on the advisability of external version Twenty-five years ago Wrigley [32] reported a fœtal mortality of 13% when the manipulation was applied under anæsthesia today the figure is likely to lie somewhere between 1 and 2% [33 34] Without anæsthesia the risk to the fœtus is significantly less [35–37] In modern obstetric practice, where fœtal survival in uncomplicated breech delivery can be 98%, the place of external version, particularly under anæsthesia, must be reviewed very carefully When the patient is to be delivered in a large maternity unit by a skilled team much can be said for White's [30] view that external version should be reserved for patients with slight or moderate pelvic contraction When external version fails and there is some doubt about the fœtal-pelvic relationship, an important decision about the mode of delivery has to be made Some obstetricians, with X-ray confirmation of even minor pelvic contraction, would favour elective cæsarean section, but where the disproportion is borderline the majority would probably be prepared to allow a trial of labour The experienced observer can learn much, under these circumstances, from the pattern of uterine contractions and the progress of labour With good pains and steady descent of the breech to the pelvic outlet there is every likelihood of a safe vaginal delivery Abnormal uterine action and failure of the breech to advance point to significant disproportion and the need for cæsarean section Hay, in his series of cases from St David's Hospital, Bangor, reports that cæsarean section was carried out in 16% and suggests that this is in keeping with modern obstetric practice In fact, the need for cæsarean section in breech presentation will vary from one hospital to another Hospitals deal with selected clinical material, and the rate of cæsarean section will depend on the ages, stature, and parity of the patients and the weights of their babies and is likely to be high when there are many emergency admissions Study of a total community would give a much truer picture of the management and results of breech presentation in any particular area and would make valid comparisons possible Unfortunately, there is at present little enthusiasm for such an epidemiological approach to obstetrics

The survival and well-being of the baby depend largely on the judgment and manipulative skill of the person who conducts the delivery The best results for mother and baby will certainly be obtained in a well-run maternity hospital where obstetrician, anæsthetist, and pædiatrician work as a team in favourable surroundings But domiciliary practice will always include cases of breech presentation undiagnosed before the onset of labour When the diagnosis is made early in labour there is everything to be said for transferring the patient to a suitable hospital When the presentation is recognised late in labour, this should be regarded as an emergency and the obstetric flying-squad summoned

Ultrasonics in Ménière's Disease

The symptom-complex of paroxysmal rotatory vertigo with deafness and tinnitus has long been recognised as a disabling condition Prosper Ménière brilliantly deduced its pathology by correctly interpreting the work of his colleague Flourens, who in 1842 observed disorders of equilibrium in pigeons after injury to the semicircular canals As early as 1883 Woakes [1] advanced the hypothesis that it was associated with increased intralabyrinthine tension—a hypothesis which was finally confirmed in 1938 by Hallpike and Cairns [2] in their classic description of the distended endolymphatic system in the labyrinth affected by Meniere's disease

No wholly satisfactory method of treatment has yet been devised This failure is due to several reasons the labyrinth is enclosed in a capsule of hard compact bone within the petrous pyramid, which makes any direct observations on its delicate neuroepithelium very difficult, the disease itself is never lethal, so opportunities for postmortem study are rare, and assessment of therapeutic results is difficult because spontaneous remissions are common and may last for many years Mental strain is said to foster attacks, possibly through sympathetic-parasympathetic imbalance resulting in hydrops of the labyrinth But, while emotional stress is often evident in Meniere's disease, this is to be expected in a condition where a fit person is suddenly struck down with acute vertigo at unpredictable moments In treatment simple sedation, vasodilators, histamine, vitamins, diets, and anti-histamine drugs are all used singly or in combination Relief of symptoms followed by remissions is achieved in a high proportion of cases, but in most

published series gradual deterioration of hearing in many cases, and development of the disease on the other side in some, have been noted Surgery is indicated when medical treatment has failed, and should be undertaken without undue delay Three main types of operation are in use intracranial section of the vestibular fibres of the eighth cranial nerve, destruction of the labyrinth, and sympathectomy In most cases the paroxysmal vertigo is relieved by the first two methods The hearing is totally destroyed by any direct operation on the vestibular end-organ, and it is often damaged by partial section of the eighth nerve Sympathectomy was introduced to preserve the hearing, but it does not always control the vertigo As Menière's disease becomes bilateral in 10–30% of cases, great efforts have been made to devise treatment that is effective and yet does not impair the hearing

The possibility of applying ultrasonic frequencies to a restricted part of the inner ear, without damaging adjacent structures, was demonstrated by KREJCI and BORNSCHEIN[3], and LUMSDEN[4] has now described his experience of ultrasonic ablation of the vestibular end-organ Ultrasonic waves do not pass from air to a solid or liquid medium (or vice versa) because they are reflected at the interfaces The bony external semicircular canal is therefore exposed surgically and ultrasound applied directly to the canal The irradiation is directed so that both the cochlea and the facial nerve are avoided Ultrasound may act by means of its mechanical, thermal, or chemical effects, but its precise mode of action on the labyrinth has not yet been established this is one objection to its routine use Undoubtedly, however, tissue destruction results from the application of suitable ultrasonic doses, and this constitutes a difficulty in clinical practice, where dosage must be based on the inexact signs of nystagmus and on previous experience ARSLAN[5] has reported the biggest series hitherto in six years' follow-up 95% of patients were free of acute vertigo and the majority had unimpaired hearing LUMSDEN found that in the first few weeks after operation modified attacks of vertigo might occur while the degeneration of the labyrinth became complete, continued vertigo usually denoted an inadequate dose A second application sometimes controlled the symptoms Facial palsy is the most important complication, but in all the reported cases spontaneous recovery has ensued The effect of ultrasound on persistent tinnitus is somewhat unpredictable, but ARSLAN seems to have had more success than some other workers

A good deal of work on the effects of ultrasound in Menière's disease remains to be done But, though still in the experimental stage, ultrasonic ablation of the labyrinth is already worth considering in cases with good hearing that do not respond to medical treatment, or where the patient is already deaf in the other ear from previous disease, labyrinthectomy, or other causes Ultrasound may eventually prove superior to all other forms of treatment[6 7]

SEWAGE AND THE BATHER

FOR some years concern has been expressed in Parliament and in the Press about the risk of contracting infectious diseases (and especially poliomyelitis) by bathing in seawater polluted by sewage A committee of the Public Health Laboratory Service has for some years been inquiring into this danger and its findings have now been published in a scientific report[1] and an abbreviated version thought suitable for politicians and journalists[2] Having reviewed evidence from many sources, the committee can say without qualification that there are no grounds for thinking that bathing in the sea involves any appreciable risk of diseases

The most popular beaches are those adjacent to large towns, and almost all these towns discharge their sewage into the sea Most samples of water from these beaches show clear evidence of fæcal pollution and some contain *Salmonella spp* in small numbers Technical difficulties make the hunt for poliovirus very difficult, but there is no reason to doubt its presence along with the other fæcal organisms The chief virtue of discharging sewage into the sea is that it is quickly diluted, and to this dilution the bathers owe their freedom from infection Except for *S typhi*, the dose of salmonellæ needed to produce disease in man is large, and, for reasons not yet fully understood, human pathogenic bacteria do not survive very long in seawater On the epidemiological side the evidence is scanty—partly because the person who has bathed has probably also eaten ice-cream, winkles, and fish-and-chips—to say nothing of looking at the peepshows on the pier

One of the major tasks of the committee was the collection of bacteriological data—counts of coliform organisms and fæcal coli—from many beaches The interpretation of these is difficult No two beaches and no two sewage outfalls are alike The vagaries of local tidal currents are unpredictable without long experience and exact tests with floats or radioctive tracers Dilution is not immediate and its efficacy will obviously depend on the distance of the sampling-point from the outfall and upon the temporary effects of wind and waves At no point within the range of the sewage outfall can the water be considered as a homogeneous fluid, and a difference of an hour (in relation to high water) can give very different bacteriological results For this reason the committee rejects the idea of a standard of bacteriological purity for bathing-beaches similar to that used for drinking-water Such standards exist in a few places in the U S A, and there is no evidence that they have had any effect on the public health or that they are enforceable The bacteriological survey has, however, some uses Sampling at short intervals along the beach, continued for many months in all sorts of weathers, will give a reasonable idea of the amount of fæcal pollution and may be essential in judging the need for a new outfall or assessing the results of such an improvement But—like a bacteriological finding in clinical medicine—it means very little unless it is considered in conjunction with all the other factors involved, and a few unplanned and irregular tests can only be misleading To compare the health-giving properties of Brinyville and Foulwater Bay by such tests is dishonest

[1] Report *J Hyg, Camb* 1959, 57, 435
[2] Medical Research Council Memorandum no 37 *H M Stationery Office* 1959 Pp 24 2s 6d

So far so good, and it is satisfactory to know that one potential source of risk to health has been given an approximate quantitative value We hope, however, that this report will not be used as an excuse for making our beaches even more foul than they are today The population of seaside towns is increasing above the average rate, and more people spend more time on the beach Because fæces and toilet-paper are not yet common objects of the seashore is no excuse for a practice which is almost always dictated by cries for economy It is true that a greater danger to health and natural beauty comes from the pollution of our estuaries (about which the committee was not concerned) The dilution factor in an estuary is variable, affected by wind, water, and the flow of fresh water, and usually insufficient. An oversight by the legislators of the last century allowed estuaries to be treated as the open sea, and the result is only too obvious in the Thames, the Dee,[3] the Tyne, and fifty other rivers As a factor in robbing the water of oxygen, sewage is ancillary to industrial effluents, and the result is a fluid which will support no form of life—except bathers (There is no more popular bathing-place in London than the plage just above Tower Bridge)

The committee did not consider the dangers of bathing in fresh water, and about this we know very little The Thames Conservancy forbid the discharge of excreta from any boat on their waters and enforce this by-law strictly Other bodies with similar problems should follow the Conservancy's example The danger of catching typhoid by bathing in the Norfolk broads may be small, but nobody knows how big it is We must be grateful to this committee for pointing out the way in which these and many similar problems can be tackled

IMMUNOLOGICAL UNRESPONSIVENESS

RECENT interest in the possible role of autoantibodies in the pathogenesis of some human diseases has been a considerable stimulus to work on fundamental processes of antibody production In this category is the study by Crampton, Frankel, and Rodeheaver[4] on the mechanism of immunological unresponsiveness Such a state of specific unresponsiveness can be induced in several species of animal by repeated injections of large amounts of the appropriate antigen[5 6], and by the use of antigens labelled with radioactive iodine Crampton and his colleagues sought to demonstrate the difference, if any, in distribution of the antigen in responsive and unresponsive animals No such differences were detected, the antigen in both series of animals being found in intracytoplasmic granules in the liver and spleen Crampton et al have, therefore, suggested that the condition of immunological unresponsiveness may result from the destruction of the specifically stimulated cells by an intracellular antigen-antibody reaction As long as an excess of antigen is made available it is presumed that sufficient free antigen will be contained in the antibody-producing cells to encompass their own destruction With the relatively minute quantities of antigen usually used to stimulate antibody formation the quantity of antigen within some, at least, of the stimulated cells is presumably too small to be lethal

The distinction between immunological unresponsiveness and immunological tolerance is noteworthy unresponsiveness is brought about and maintained by repeated injections of large quantities of antigen at almost any period of life tolerance is a more or less permanent state induced by the injection of living cells within a very short period of birth[7] Since the persistence of tolerance also requires the survival of the injected foreign cells or their descendants the final mechanism may well be the same—namely, self-destruction of the specifically stimulated cell, the result of intracellular reaction of antigen and antibody

A particularly attractive feature of this hypothesis of Crampton et al is the explanation that it affords of the differences between a primary and a secondary response Thus, following primary stimulation by a small amount of antigen the antibody that subsequently appears in the plasma is the product of those specifically stimulated cells that have survived any intracellular antigen-antibody reaction Whatever is the precise nature of these cells when first they make contact with antigen they subsequently acquire the cytological characteristics of plasma cells, and thus have apparently lost the ability to take up antigen intracellularly Since they continue to secrete specific antibody protein it is reasonable to assume that they are still capable of reacting specifically with any future access of antigen It is postulated, however, that such a surface interaction results, not in death, but in stimulation to proliferation The secondary response is therefore characterised by both its speed and its magnitude

A slightly different but even further reaching hypothesis was put forward by Burnet in 1957[8] This too requires that according to circumstances the antibody-forming cells are killed or excited to reproduce. The recent work of Crampton and his colleagues offers a plausible explanation of the way in which these strikingly different results could be brought about

THE GAMMA SYSTEM IN MAN

THE gamma system comprises the small-diameter efferent nerve-fibres which originate from small anterior-horn cells, together with the intrafusal muscle-fibres which they supply within the muscle spindles As Leskell[9] originally showed in cats, this system can change the sensitivity, or bias, of the primary (annulospiral) sensory endings to imposed stretch Subsequently both the functioning of the gamma system and its supraspinal control have been intensively studied Apparently, in many postural reflex contractions of striated muscle, nerve impulses are initially routed from the spinal cord via the small efferent fibres to produce a shortening of the intrafusal muscle-fibres This shortening stretches the primary sensory endings and increases their afferent discharge The resultant enhanced bombardment of large anterior-horn cells leads to contraction of the extrafusal striated muscle-fibres, which diminishes the spindle afferent discharge. The primary sensory endings here operate as null detectors, discharging afferent impulses at a rate which is proportional to the differing lengths of the intrafusal and extrafusal muscle-fibres This conception of the muscle-spindle's function enlarges the earlier view that the spindle acted merely as a detector of muscle stretch, though both of these activities ultimately depend on stretch of the primary sensory ending Merton[10] further suggested that

the gamma system might play an essential part in the execution of certain willed movements He postulated that descending impulses from the supraspinal centres controlling willed movements might be routed to the small anterior-horn cells and thus produce willed contraction of striated muscles over the same pathways as those of postural reflexes

From all this work it seemed that the gamma system might be of considerable importance in man Many of the observations on man are based on a finding of Hoffmann [11] that the medial popliteal nerve may be electrically stimulated in such a way as to produce a pure reflex contraction of the gastrocnemius-soleus muscle-group This H reflex [12] was thought to follow the same reflex pathway as the ankle-jerk, but to differ from the tendon reflex in so far as the muscle-spindles (and the associated gamma efferents) were removed from circuit Differences in the responses of the ankle-jerk and the H reflex could thus be equated with the degree of activity in the gamma system

Sommer [13] observed that Jendrassik's reinforcement potentiated the ankle-jerk while leaving the H reflex unaltered, the experiments were repeated by Paillard,[14] and reinforcement has been ascribed to enhanced activity of small motor-fibres leading to increased sensitivity to stretch of the primary spindle-endings Similarly Buller [15] suggested that the hyperreflexia of early hemiplegia is due to resetting of the muscle-spindles on the abnormal side, and Benson [16] has argued that some labyrinthine reflexes are effected via the gamma system The validity of all these arguments rests on the assumption that the central reflex pathways of the ankle-jerk and the H reflex are identical But Magladery and Teasdall [17] have shown that in man probably neither the ankle-jerk nor the H reflex pursue purely monosynaptic paths, and they have questioned whether the ankle-jerk and H reflex do follow identical central pathways If the pathways are different—if, for example, the spinal pathway subserving the ankle-jerk includes an interneurone which is not also activated during elicitation of the H reflex—then supraspinal control of that intraneurone [18] might explain the differences between the tendon-jerk and H-reflex responses attributed by Sommer,[13] Buller,[15] and Benson [16] to gamma-system activity Thus, while the observations of these three workers suggest that the gamma system is functionally important in man, they do not prove it

Further indirect evidence of the existence of tonic gamma-system activity during the waking state is provided by the observation of Buller and Dornhorst [19] that local infiltration round the medial popliteal nerve with cinchocaine abolishes the ankle jerk while leaving the H reflex unaltered By analogy with the differential gamma-fibre blocks produced in the cat with procaine,[20] Buller and Dornhorst suggested that they had selectively blocked the gamma efferent fibres to the muscle-spindles supplied by the medial popliteal nerve If this is correct, it would seem that in the waking state the intrafusal muscle-fibres are continuously under gamma control, and therefore probably accessible to reflex or supraspinal control

All these observations on man have been concerned with the tendon-jerk The gamma system also takes part in determining the static stretch reflex, which is estimated clinically as muscle tone That the tendon-jerks and muscle tone may vary independently is known from clinical experience, and has been clearly shown by Hammond [21] The explanation of this independence probably lies in the separate supraspinal control of synapses on the central pathway for tone which do not form part of the spinal pathway of the tendon reflex Such synapses may be at interneurones and/or Renshaw cells While the discharge from the muscle-spindle (itself determined by gamma activity) is important in determining both the tendon reflex and muscle tone, differences in the intraspinal pathways of these two reflex arcs allow independent supraspinal control

Thus, in man there is indirect evidence that the gamma system plays a part in both the phasic and the static reactions of the stretch reflex It seems likely that gamma efferent activity is maintained throughout the waking state and may be modified as part of normal postural reflex activity, and also as a result of damage to the central nervous system The part played by the gamma system in willed movement is still unknown

NEW YEAR HONOURS

In recognition of his presidency of the Royal College of Surgeons, Sir James Paterson Ross receives a baronetcy Even before his election, Sir James did much for the college in the congenial role of dean of the Institute of Basic Medical Sciences, and in the difficult period of financial reconstruction that has coincided with his term of presidential office the college has been fortunate in having at its head a man so much respected alike as a surgeon, as a teacher, and as a person Similarly, as president of the Royal College of Obstetricians and Gynæcologists, since 1957, Prof Andrew Claye has given a great deal of time and thought to its development, and his knighthood will give pleasure both on public and on personal grounds Dr Ivan Magill, who is promoted to a knighthood in the Royal Victorian Order, is one of the innovators who have created modern anæsthesia, and by his tubes, his laryngoscope, and his rebreathing bag his name is known wherever this art and science are practised As a practical prophet, he is very far from being without honour in his own country Prof Derrick Dunlop not only has been chairman of the British Pharmacopœia Commission, and much else that officially justifies his knighthood, but also is a great Edinburgh personality and memorable teacher Moreover, unlike so many knights nowadays, he lives in a real castle In Australia, Sir Charles Blackburn, who is created K C M G, was knighted in 1936 and has been chancellor of the University of Sydney since 1941 he is consulting physician to the Royal Prince Alfred Hospital Of the knights bachelor, Prof Edward Ford became director of the School of Public Health and Tropical Medicine in Sydney in 1947, having done much work in the Army which his colleagues rated especially high, and Dr W W S Johnston, who has a fine record during and after both world wars, has been consulting physician to the Royal Melbourne Hospital, and chairman of the Melbourne Permanent Postgraduate Committee, for four years Prof J P Walsh, now K B E, is dean of the University of Otago Dental School

The remainder of the list published on p 106 contains the names of many other medical men and women who are held in high regard by those who work with them and by those for whom they work

HOTELS OR HOSPITALS?

J A Stallworthy
M.A Oxon, M B N Z, F.R.C S, F R C O G, Hon F A C S
DIRECTOR, AREA DEPARTMENT OF OBSTETRICS AND GYNÆCOLOGY, UNITED OXFORD HOSPITALS

There can be no dispute concerning the national need for new hospitals Conflict of view on what form they should take, and what function they should serve, may provoke original thought and avoid perpetuating unfortunate and costly errors It would be flippant to suggest that the Government should build expensive hotels in which hundreds of thousands of citizens could live expensively but free (in so far as anything paid for by taxes is free) for such varying times as they or their doctors considered their health was below par Unfortunately, however, there is a real danger that many of the millions pledged for hospital construction may provide hotels instead—and very expensive ones! The name "St Trinian's Hospital" rather than "Hotel Sans Souci" in neon lights over the palatial entrance to a modern skyscraper will not alter the use made of its beds

Intelligent planning and bold but reasoned experiment are necessary to build a hospital service worthy of the latter half of the 20th century and not a mere chromium-plated replica of a system now outmoded A revolution in building and administration must be preceded by a revolution in thought Most people find revolutions disturbing, but, in fairness to Governments that build and citizens who pay, a warning seems justified To clamour for the spending of £750 million is foolish unless guidance is given on how it may best be spent Wise planning and spending could result in Great Britain leading the world in a new concept of hospital service

Great advances in medicine have transformed the legitimate demands that should be made on hospitals Diagnosis is more rapid and accurate, and to an increasing extent is, or should be, an outpatient procedure, whereas previously it was not unusual for patients to occupy hospital beds for days and even weeks "under observation" while a diagnosis was made (Although the justification now seldom exists, the practice is not entirely obsolete) Treatment is now more precise Where patients were once admitted with acute infections from which many died and others required long periods of intensive nursing, most are now treated effectively at home by the family practitioner Developments in anæsthetic and surgical techniques have revolutionised surgery The patient is no longer an invalid for weeks or months after a simple abdominal operation He serves tea to his fellow patients a few days after a bowel resection or a lobectomy, and feels the better for it! Emphasis on positive health and rapid rehabilitation is increasing The illness or the operation is an unfortunate interlude to be forgotten as soon as possible, and the whole hospital service should be so designed and maintained as to facilitate this process

VALUE FOR MONEY

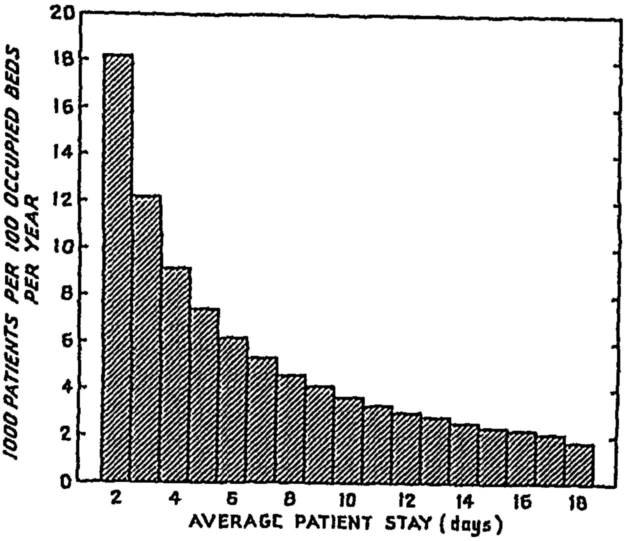
New techniques can demand highly specialised and expensive equipment and staff, and add to capital and maintenance charges This is one excuse made for the high cost of the present hospital service, and will doubtless be used to justify greater expenditure in the future The excuse is only partly valid Accumulating evidence in published estimates suggests that it is widely accepted that hospital construction must be relatively expensive, even when special facilities and equipment are either not required or are minimal For example the cost of new "acute" hospitals, planned or recently built, varies within a range of £3000 to £6000 a bed Even the lower figure is nearly three times the estimated cost of accommodation per guest in new luxury hotels now being built in the London area It is true that hospital charges expressed in this way include the cost of theatre suites, expensive equipment, nurses' accommodation, &c, but it is also true that with hotels the estimate provides for public rooms, ballrooms, restaurants, private bathrooms with every bedroom, and the other amenities considered essential in a modern hotel of international repute This comparison is not to suggest that one is too expensive or the other surprisingly cheap, for only those with an intimate knowledge of all the factors associated with modern building could evaluate the two It should however emphasise the great cost of a modern acute hospital and the relative expense of simpler institutions used in the hospital service

If hundreds of millions sterling are to be spent on building, it is essential that the Government and the taxpayer receive value for the money Expensive equipment should be used as far as possible solely for the purpose for which it was designed, and to the maximum of its capacity industry achieves efficiency in this way A surgical theatre suite makes its contribution to each patient in a relatively short time varying from minutes to hours Too often, however, theatre and other expensive facilities are limited in the work they could do because beds are fully occupied In the meantime waiting-lists grow with all the associated implications of disordered homes and absence from work The generally accepted solution to the waiting-list problem appears to be "more beds" This would mean bigger hospitals, or more of them, with a corresponding increase in the cost of the hospital service To adopt this policy would be short-sighted, for there are weighty arguments to support the view that a more efficient service could be provided with smaller acute hospitals and fewer beds Factors already discussed are decreasing the demands made on certain sections of hospital beds at present available in fever and other hospitals Many of these beds could now be used to advantage as suggested later

STAY IN HOSPITAL

With these general concepts in mind, study of the Ministry of Health national costing returns for 1958 discloses some startling facts Even the official definitions used are relevant An "acute" hospital is one in which *not more than 15%* of the beds are "allocated to the excluded departments" This means set aside for the use of chronic sick and other categories of non-acute conditions A "mainly acute hospital" can have *up to 40%* of its beds allocated to these purposes This should be remembered when one considers the equipment, staff, and expense of a modern acute surgical or medical unit To serve hot dogs at a shilling a time in the Savoy Grill would be uneconomic, and so is the established practice of keeping convalescent patients in acute hospital beds What is urgently needed is a reappraisement of what is meant by a convalescent patient

The 1958 report records that hospital A (a famous London teaching hospital of about 700 beds) had an average stay per patient of eighteen days Hospital B (a teaching hospital of about 400 beds) had an average stay



Graph to correlate the number of patients who could be treated in 100 occupied beds with the average number of days they spend in hospital

of nine days There must inevitably be many factors other than the time patients are kept in hospital which differ in the two institutions, but they have this in common that both are general teaching hospitals with special departments, and both have reason to be jealous of the high standard of medical care provided The 700 beds in hospital A treated just under 14,000 inpatients in the year, while hospital B with 400 beds treated nearly 17,000 If hospital A reduced its average stay per patient to nine days it would double the number of patients treated to 28,000 If these patients were not available it could either close beds and reduce the size of staff, or admit from the waiting-lists of other hospitals working under greater pressure Furthermore, if hospital A were scheduled for rebuilding, it would be unrealistic to claim that it should be reconstructed as a 700-bed unit unless a reasonable case were made to justify this in terms of increased medical demands expected to be made upon its services

Conversely, if hospital B (average patient stay of nine days) decided for some reason it would work to a basis of an average stay of eighteen days, it would treat only 8500 inpatients instead of 17,000 as at present This would increase further its already huge waiting-list to such an extent that a public outcry (though misinformed) would almost certainly demand more beds and more staff To treat the same number of patients as at present, only with an eighteen-day average stay, it would need to double its size to 800 beds

This perhaps oversimplifies the position, but the available evidence in hospital and national reports confirms the basic truth of the argument No London teaching hospital in 1958 had an average stay of less than fourteen days and the range was up to twenty-four In the provincial teaching hospitals the range was nine to sixteen days The non-teaching acute hospitals of the Metropolitan area and the country as a whole had a corresponding variation in the average stay of patients An increase from ten days to twelve days per patient may seem small, but it represents a fall of about 15% in the contribution a hospital has been making and in terms of national figures it is of tremendous importance The chart demonstrates how the number of patients 100 occupied beds can handle in one year is related to the average length of stay

A low average figure is not in itself a goal to be aimed at, but it emphasises certain facts which are often overlooked The patient who stays in hospital a day longer than necessary *uses the hospital as a hotel* Major discrepancies between the average stay in hospitals of comparable size and purpose are a measure of the extent to which at the present time hospitals are used as hotels It is ironical that in many cases a patient could be more comfortable, have greater privacy, better food, and more quiet at approximately half the cost if he were in a hotel with several stars to its credit

Destructive criticism is easy, but a problem as vast and important as the National Hospital Service demands a constructive approach Any major reform is certain to challenge many traditional concepts and may arouse powerful opposition Experiment with pilot schemes can be valuable, for once facts prove a contention it is difficult for opposition to survive

BETWEEN HOSPITAL AND HOME

The phase of acute illness in medical and surgical diseases is now generally short A period follows of varying length during which there could be no better place in which to recover than at home under the supervision of the family practitioner, provided the necessary facilities exist and the patient and relatives desire it In America this early return home has been made necessary by the high cost to the patient of hospital care Hospital costs in Great Britain are also high, and are steadily increasing, but the Welfare State protects most patients from any personal financial strain when, with the acute episode safely over, they prolong their stay and convert the hospital into a hotel Unfortunately home conditions in Great Britain seldom warrant an early transfer, but with rising standards of living, better housing, and an effectively organised home-help service, it would be reasonable to expect improvements in the future

A major criticism of the present service is that little thought has been given to the problem of how to bridge the gap between the acute episode and the time when the patient could reasonably return home Early convalescence is usually spent in wards designed, equipped, and staffed for acute work In his excellent article on Hospitals for Today and Tomorrow[1] Farrer-Brown referred to a Nuffield Provincial Hospitals Trust survey team's findings that a quarter of the patients in medical beds in a general hospital could have been treated at home or in the outpatient department, and that nearly half remained in hospital longer than was necessary Those who need the facilities of an acute unit are kept waiting by those who do not

The solution is obvious Hospitals designed for acute work should be used for that purpose and *for that purpose only*, with early patient transfer to a simple, quieter, less expensive environment where medical and nursing requirements would be minimal Emphasis would be on self-help and rapid rehabilitation

Practical experience of this concept has revealed the advantage of the consultant responsible for the management of the acute phase of the disease retaining control in the convalescent annexe, but there is every reason to explore to an increasing degree cooperation with the family practitioner once patients have been transferred

The siting of these annexes could well vary according to local conditions Small towns can no longer have a modern and efficient hospital (This suggestion may be resented by some but it is an economic and medical fact)

---

[1] *Farrer-Brown, L. Brit med J* 1959, i, suppl p 188

These towns, however, could be equipped with the new-purpose annexe and in this way allow their citizens to return among friends and relatives a few days after operation, or once the acute phase of illness was over This would help integrate general practitioners into the hospital service and facilitate continuity of care by the family doctor In the cities these convalescent annexes could be more closely associated with the acute hospital units, and, where space permitted adequate access to the open air and to gardens, it would probably be more economical to have them close to the acute unit In the meantime, however, use should be made of empty beds in fever hospitals and chest units

ADMINISTRATION AND NURSING

A 1000-bed hospital of the type now envisaged would differ from the present 1000-bed hospital in many ways, including nursing and administration Staffing of the acute unit would need to be generous, otherwise the strain would be too great In the annexe, however, staffing would be minimal, and all possible use could be made of part-time workers The scheme suggested could help solve the nursing problem not only of Great Britain but of other countries as well It should also lead to a reassessment of the great expansion of hospital administrative personnel since the appointed day The Whitley Council system of paying certain staff on a points-per-bed (or cot) basis might be more efficient under the proposed scheme than under the present one

It may be argued that this plan would make nurse training harder If the responsible authorities wish to continue training nurses as at present, there would be weight in the criticism, but the changing face of medicine has modified the conventional pattern of nursing duties This fact is being too often overlooked, with the result that nurses spend time and energy in badly designed wards carrying unnecessary bedpans, wash bowls, and food dishes to patients who would be much better and much happier attending to their own needs if only facilities existed for them to do so In their hours of study nurses are trained in medical and surgical detail to an extent which would enable many to compete favourably in examination with medical students, and it is certain that this increased knowledge is not an essential to devoted, sympathetic, and skilful nursing (It can in fact be a handicap) In acute wards detailed nursing care is essential, but in the annexes the attention required would be slight Adequate rest and recreation rooms, ample bathroom and lavatory accommodation, cafeteria feeding, and modern kitchen and cleansing equipment, would reduce domestic staff to a minimum Conditions would be ideal for nurses from acute units to relax while acting merely in a supervisory capacity during spells off acute duty The psychological advantage to a patient of being transferred early from the hospital atmosphere of acute wards to the simpler and more relaxed life of the annexe would be considerable

WARD/ANNEXE BED RATIO

The ideal relation between the number of acute and annexe beds would vary from specialty to specialty and would require considerable preliminary experiment. The greater the number of annexe beds in effective use the cheaper would be the hospital service From experience of practising these ideas at Oxford we believe that in gynæcology a reasonable relationship would be 30 annexe beds for an acute ward of 24 beds At no time have the convalescent facilities at Oxford been either adequate or sufficiently stable for a continued practical trial, and the ratio suggested may need adjustment after further experience Any alteration would probably be to increase the proportion of annexe beds

DEDUCTIONS FROM OXFORD EXPERIENCE

In the area department at Oxford 39 acute gynæcological beds accommodated 1991 surgical patients in 1958 and have averaged 1814 a year over the past five years 24 of these beds are at the Churchill Hospital and 15 at the Radcliffe Infirmary Because of shortage of convalescent beds the practice has been to give the Radcliffe priority over the Churchill in the use of beds available The result has been that in 1958, with the same consultant staff, 925 operations were performed from the 15 Radcliffe beds, and 1066 from the 24 Churchill beds With an adequate senior staff and constant use of even the limited convalescent facilities used by the Radcliffe, the Churchill would have been able to operate on at least 1500 patients without being given any extra acute beds This would have reduced the gynæcological waiting-list from over 600 to practically zero within a year The next step would be to *reduce the number of acute beds*

Allowing an average stay of five days in the acute ward for major operative cases (many would require less) and ten in the annexe, a unit of 24 acute beds and 30 annexe beds should be able to treat 1500–2000 patients a year Those requiring special investigations would be admitted to the annexe in the first instance, be transferred the day before operation, and return a few days later For this volume of work the 24 acute beds would require theatre facilities for at least three major lists a week, preferably with two theatres available for each Daily access to a theatre, even if for only an hour, would enable minor cases and " day " cases to be handled in considerable numbers if a few beds were set aside for patients requiring minor procedures such as cystoscopies, pyelograms, and biopsies Even these demands would occupy less than half the available theatre time The remainder could be utilised by a comparable surgical unit handling approximately the same number of patients Thus a basic acute unit of two wards of 24 beds each, and a theatre suite of two theatres with a recovery room, should be able to treat surgically a minimum of 3000–4000 patients a year The size of the theatre suite would obviously be developed in proportion to the number of acute wards attached, but it will be apparent that a suite of four theatres serving four wards with a total of just under 100 acute beds could on the above figures treat 6000–8000 surgical patients a year This may well be an underestimate

To appreciate what this means in terms of present practice, these 100 acute surgical beds with their associated annexe facilities could treat annually at least as many surgical patients as the total of all patients at present admitted to some acute hospitals, teaching and non-teaching, of 300–350 beds A comparable reduction in the number of acute medical beds at present in use would seem reasonable The result would be acute hospitals of reduced size and improved efficiency, one indication of which would be the virtual abolition of long waiting-lists

In this concept of an acute hospital service we should need staff sufficient to use the facilities to full capacity, but there should be flexibility The idea of a consultant being given *x* beds on his appointment to a hospital and regarding these as his own for the remainder of his active life, to be increased possibly but never decreased, is outmoded and uneconomic It is hard to justify consultants (or teams of consultants) in any specialty retaining a considerable number of beds when they have almost no waiting-list, while the staff in another department struggle in vain against a constantly increasing pressure of work. Admittedly the number of operations competently performed in a session is not the only index of a surgeon's contribution, but we can be pretty sure that two surgeons working as a team will do more than they could if they worked separately—and will do it with less effort. Particularly is this so when the clinical load is heavy and when two theatres are used at one operating session. When one consultant was away, or when pressure of waiting-lists required it, beds might be diverted temporarily from one service to another. These are points which should be decided on grounds of need and common sense rather than privilege or pride.

In the scheme here outlined an essential to success would be efficient teamwork by all concerned—doctors, nurses and administrators—determined to utilise to the full their resources. By so doing they would render the greatest possible service to patients at the lowest possible cost.

To explore the potential advantages, and also the difficulties both foreseen and unforeseen, a pilot trial would be necessary. In terms of the projected £750 million building programme this would be inexpensive, but its results could be far-reaching.

SUMMARY

Medical and surgical advances have changed the demands that can legitimately be made on hospitals. They are not hotels.

Hotels are cheaper than hospitals to build and maintain.

A positive attitude to health should reduce to a minimum the time a patient spends in hospital.

The acute episode of illness is usually short but its efficient hospital treatment is expensive.

Acute beds should be used for acute work only, and should be integrated with relatively inexpensive annexes. Estimates are given of the clinical potential of an acute surgical unit with annexe facilities.

The acute hospital of tomorrow could be much smaller and more efficient than its present counterpart.

An experimental pilot trial is advocated.

NEW YEAR HONOURS

THE list of honours published on Jan. 1 contains the names of the following members of the medical profession.

Baronet

Sir JAMES PATERSON ROSS, K.C.V.O., M.S. Lond., LL.D. Glasg., Hon. F.R.A.C.S.
President, Royal College of Surgeons of England, professor of surgery in the University of London at St. Bartholomew's Hospital Medical School.

K.C.M.G.

Lieut.-Colonel Sir CHARLES BICKERTON BLACKBURN, O.B.E., M.D. Sydney, F.R.C.P., F.R.A.C.P., R.A.A.M.C. retd.
Chancellor of the University of Sydney.

K.C.V.O.

IVAN WHITESIDE MAGILL, C.V.O., M.B., D.A. Belf., F.R.C.S.

K.B.E.

JOHN PATRICK WALSH, M.B. Melb., D.D.SC., F.D.S. R.C.S.
Dean, University of Otago Dental School.

Knights Bachelor

ANDREW MOYNIHAN CLAYE, M.D. Leeds, Hon. M.D. Melb., F.R.C.S.
President, Royal College of Obstetricians and Gynæcologists, professor of obstetrics and gynæcology, University of Leeds.

DERRICK MELVILLE DUNLOP, B.A. Oxon., M.D., Edin., F.R.C.P., F.R.C.P.E.
Professor of therapeutics and clinical medicine, University of Edinburgh.

EDWARD FORD, O.B.E., M.D. Melb., F.R.C.P., F.R.A.C.P.
Director of the School of Public Health and Tropical Medicine, Commonwealth Department of Health, University of Sydney.

WILLIAM WALLACE STEWART JOHNSTON, C.B.E., D.S.O., M.C., E.D., M.D. Melb., F.R.A.C.P.
Consulting physician, Royal Melbourne Hospital, for services to postgraduate education.

C.B. (Military)

Surgeon Rear-Admiral DOUGLAS MURDO BEATON, O.B.E., L.R.C.P.E., Q.H.P.

Major-General FRANK MCLEAN RICHARDSON, D.S.O., O.B.E., M.D. Edin., Q.H.S.

Major-General THOMAS FREDERICK MACKIE WOODS, O.B.E., M.D. Dubl., Q.H.P.

C.M.G.

JOHN CAIRNEY, M.D., F.R.A.C.S.
Director-General and Inspector-General of Hospitals in New Zealand.

C.B.E. (Military)

Air Commodore WILLIAM PERCIVALE STAMM, M.B. Lond., F.R.C.P., Q.H.S., R.A.F.

C.B.E. (Civil)

STANLEY ALSTEAD, M.D. Lpool, F.R.C.P., F.R.C.P.E., F.R.F.P.S.
Regius professor of materia medica and therapeutics, University of Glasgow.

LOUIS ABEL CÉLESTIN, M.C., M.D. Lond.
For public services in Mauritius.

THOMAS FRANK DAVEY, O.B.E., M.D. Manc.
Senior specialist (leprologist), Eastern Region, Nigeria.

GEORGE LIGHTBODY MONTGOMERY, T.D., M.D. Glasg., PH.D., F.R.C.P.E.
Chairman, Scottish Health Services Council, professor of pathology, University of Edinburgh.

TIMOTHY JOSEPH O'LEARY, M.B. N.U.I.
Senior flying doctor in Queensland, Royal Flying Doctor Service of Australia.

ROBERT WILFRED SCARFF, M.B. Lond., F.R.C.S.
Professor of pathology in the University of London at Middlesex Hospital Medical School.

LEONARD ANTHONY PAUL SLINGER, O.B.E., M.B. Cantab.
Director of medical services, British Guiana.

DOROTHY MARY TAYLOR, M.D. Edin., D.P.H.
Senior medical officer, Ministry of Health.

O.B.E. (Military)

Lieut.-Colonel THOMAS WELSH CARRICK, M.B. Glasg., R.A.M.C.

Colonel RICHARD GEOFFREY CHAMPION DE CRESPIGNY, E.D., M.B. Melb., F.R.A.C.P., R.A.A.M.C.

Surgeon Commander JOHN GLASS, F.R.C.P.E., R.N.

O.B.E. (Civil)

ALFRED BIMBISARA ABAYOMI-COLE, M.B. Durh.
Senior medical officer, Sierra Leone.

ROBERT CALDERWOOD, M.B. Glasg.
Lately deputy secretary, Ministry of Health, and deputy director of medical services, Singapore.

STANLEY WALKER COOPER, F.R.C.S.E.
Surgical specialist, Ghana Medical Service.

WILLIAM ALEXANDER CRAMOND, M.D. Aberd.
Physician-superintendent, Woodilee Mental Hospital, Lenzie.

JOHN RALPH DONALDSON, E.D., M.B. Melb.
Formerly commissioner, St. John Ambulance Brigade, Western Australia.

WILLIAM GLYN EVANS, M.B. Wales.
Lately director of medical services, Sarawak.

SOYODE OBAFUNMILAYO OLUMUYIWA FRANKLIN, M.B. Dubl.
Chief medical officer, Ministry of Health and Social Welfare, Western Region, Nigeria.

JEAN ARTHUR GEMMILL, M.B. Edin.
Medical superintendent, maternity clinic, Aden.

CHARLES HENRY GURD, M.D. Brist.
Physician-specialist, Fiji.

ALAN WAITES HANSELL, M.B. Lond.
General practitioner and medical officer of health, Bedale, Yorkshire.

IAN WILLIAM JAMES MCADAM, M.B. Edin., F.R.C.S.I.
Professor of surgery, University College of East Africa, Makerere.

DUNCAN MACMILLAN, M.D. Edin., F.R.C.P.E.
Physician-superintendent, Mapperley Hospital, Nottingham.

JOHN ALEXANDER MCVICKER, M.B. Belf.
Member, Northern Ireland General Health Services Board.

ELIZABETH THEODORA MESS, M.B. Lond., F.R.C.S.I.
For public services in the Northern Region, Nigeria.

ALBERTO MARIA RODRIGUES, M.B.E., E.D., M.B. Hong Kong.
For public services in Hong Kong.

DAVID SCOTT, M.D. Camb.
Specialist epidemiologist, Ghana Medical Service.

HELEN ROSAMUND BARTER SNOW, M.B. Lond.
Principal, Christian Medical College, Ludhiana.

DOUGLAS ERIC THOMPSON, M.B. Camb.
Senior medical officer, Tanganyika.

HUGH BRYSON CALWELL WALLACE, M.D. Belf.
Specialist physician, Malayan Medical Service
MAURICE HOLLAND WEBSTER, M.B. Aberd.
Director of medical services, Northern Rhodesia, for his work in providing a health service during the construction of the Kariba Dam
BASIL DUDLEY WHITWORTH, M.B. Camb.
Director of medical services, Swaziland

M.B.E. (Military)

Major DOUGLAS STUART PATON, M.B. Brist., R.A.M.C.

M.B.E. (Civil)

JAMIETRAM KRISHNARAM DAVE, L.C.P.S.
For public services in Tanganyika
FRANCES MARY HANCOX
Medical missionary in Colombia
WALTER PARKER HARRISON, M.R.C.S.
Member, National Service medical board, Lincoln
WILLIAM ALFRED CONRAD HORTOR, M.R.C.S.
For public services in Jamaica
ADAM SOLTYSIK, M.D. Lwow
Surgeon specialist, Grenada, Windward Islands
HENRY THOMPSON STRUDWICK
Medical officer, Jamaica

Occasional Book

GODEL'S PROOF

IN these days of automation, mechanical translation, and computer-made election forecasts we find mathematics everywhere pervading daily life. We are almost approaching the point where it will be the man who fears mathematics, rather than the absent-minded mathematician, who is unfitted to deal with his environment. It is therefore consoling to hear of a mathematician who can prove that the foundations of the forbidding edifice of reason erected by men such as Bertrand Russell are little more secure than those supporting the ramshackle huts of commonsense which most of us inhabit.

Two American mathematicians, Ernest Nagel and James R. Newman,[1] have lately set out to bring before a wider public the Incompleteness Theorem in which Godel shows that mathematics contains an inevitable loophole, which may be looked upon either as a fatal defect or else as a vital element of flexibility which saves it from ultimate sterility, depending on the point of view.

Kurt Gödel was born a Czech in 1906 and showed the usual early interest in mathematics. In 1924 he moved to Vienna, there reaching a post equivalent to that of assistant professor in 1933. By then his interests included the philosophical implications of mathematics and it was in 1932 that he made his most individual contribution, by proving, in his own phrase, the "inexhaustibility" of mathematics and publishing his theorem. In 1938 he emigrated to America to work at the Institute of Advanced Studies in Princeton, where he came under Einstein's influence and much of his later work has been concerned with relativity. In 1951 he was co-recipient of an Einstein award.

The proof of his theorem requires the use of a code according to which every possible mathematical statement, argument, symbol, or proof can be translated into terms of a new language. A translation of this kind is loosely similar to translating (say) English into French, but just as a mathematical language or "calculus" is more exact and unambiguous than any ordinary verbal language, so also a mathematical translation or "mapping" is more rigorous and formal than an ordinary linguistic translation.

We may describe a Gödel mapping as a coding procedure capable of converting a page of mathematical argument into a sequence of entirely numerical formulæ. For example, the identity $0=0$ becomes the Gödel Number $2^6 3^5 5^6$ (i.e., 243,000,000) according to the rules of the procedure, and any other sequence of basic mathematical-logical symbols can similarly be represented by a unique Gödel Number. Any Gödel Number can be broken down into its factors in order to arrive at the original mathematical-logical sequence which it represents and as a result of the rigid correspondence between the two parallel languages, the arithmetical relationships existing between different Gödel Numbers stand for relationships between the equivalent statements in ordinary mathematical logic. In other words, statements about Gödel Numbers are statements about mathematical logic (as distinct from statements *within*, or expressed in, mathematical logic). Furthermore the coding-rules devised by Gödel are such that the ordinary laws of arithmetic apply to Gödel Numbers—they may be multiplied, divided, factorised, and so on, as if they were ordinary numbers with no special meaning. It follows not only that arithmetical manipulations of Gödel Numbers are possible and that they are logical statements about logic, but also that the logic in which these statements are made is similar to the logic about which they are made.

When a language (composed of words or symbols of any other kind) is used in order to discuss some other language, such discussions are said to be carried on in a "meta-language". Statements about mathematical logic are therefore called "metamathematical", no matter what terms they are couched in, because mathematical logic constitutes a language, and metamathematical assertions, as we have seen, can be expressed as more or less simple calculations with Godel Numbers. Since the rules of these calculations are identical with the rules of the original mathematical calculus under discussion, it is clear that in this case the rigour of the meta-language is no greater and no less than that of mathematics itself.

Now it is obvious that mathematics cannot possibly be wholly translatable into another set of symbols (such as the Godel Numbers) until it is itself expressible in a finite number of symbols. One cannot make a strict translation from French into English of ideas which a Frenchman cannot accurately express in French. The attempt to make mathematics formally and fully expressible has been undertaken by various authors, Bertrand Russell among them, and it is what mathematicians mean by the axiomatic method.

The axioms are the basic unproved assumptions of the system. They are expressed in symbolic form as a set of statements and the symbols are of two types—variables and connecting-signs. The meaning of the axioms resides in the fact that the variables are only allowed to be connected in strictly specified ways—the axioms are in fact the exposition of the ways in which the variables and connecting-signs may be combined, reduced to the simplest terms. In addition to the axioms other "formulæ" can be made up from the same symbols. Formulæ are the formal symbolic equivalent of sentences in ordinary language and the progression from one step of an argument to the next depends on altering the first formula (or sentence) into the next, or combining two formulæ already derived, to produce a third. Strict rules define the permissible ways of making these combinations and substitutions.

A little thought will show that the axioms and the transformation rules together make up the arbitrarily established rational basis of the entire system and are, in short, its "dogma". The symbols serve only as tokens to be manipulated in obedience to the restrictions of this dogma. The axioms of a formal system must all be tautologous—that is to say that the structure of these statements is such that they remain valid irrespective of their content. For example, the algebraic identity $(a+b)(a-b)=a^2-b^2$ is a tautology and it can be verified by substituting for "a" and "b" any numbers we choose In the same way, the logical axiom $(pVq) \supset (qVp)$ is tautologous and conveys the same logical attitude about alternative possibilities, whatever phrases or sentences may be substituted for p and q Furthermore, the transformation rules are such that every formula derived from the axioms by their application must also be a tautology, such formulæ are called theorems On the other hand, it must also be possible to combine the symbols of the system in such a way that a formula results which is not tautologous, is not derivable from the axioms via the rules, and is therefore not a theorem Oddly enough at first sight, this last is a necessary condition if the axiomatic system is to be consistent, for the following reason

---

[1] Nagel, E., Newman, J. R. Godel's Proof. London: Routledge & Kegan Paul. 1959. Pp. 112. 12s. 6d.

By "consistency" is meant that the dogma of the system is such that it is impossible to derive from it both a proposition and its formal contradiction, this is obviously an indispensable condition of rational thought It can be shown that if both the proposition and its negation can be derived in a single instance, the same can be done for all propositions, therefore, any proposition whatever can be proved and the system is valueless Conversely, however, if it can be shown by metamathematical argument that there is a single proposition which cannot be proved, it follows that the system is consistent and rational To prove a system consistent, all that is needed is to discover a single formula which can be shown *not* to be demonstrable from the axioms via the rules and is therefore not a theorem To prove in addition that a formalised system is *complete* requires a metamathematical demonstration that every true statement expressible in terms of the symbols of the system must also be capable of step-by-step derivation from the axioms

What Godel did was to construct the Godel Number corresponding to a certain formula, this formula being expressed in what purported to be a complete and consistent axiomatic calculus He also constructed the Number for the negation of this formula Clearly, one or the other of these numbers must represent a true statement Now, the formula in question was the metamathematical statement that *the formula itself could not be derived* from the axioms via the rules Thus, either the formula (and the statement) are true, in which case the formula cannot be proved, or else the negation of the formula must be true, in which event the statement must be false and the formula therefore demonstrable although false Consequently mathematics must either be incomplete or inconsistent, for (when strictly coded into Godel's meta-language) it permits of the construction of this paradoxical formula

By similar methods Godel showed that it was possible to construct a Godel Number corresponding to the assertion "The calculus is consistent"—i e, "There is at least one formula in the calculus which is not demonstrable"—and then to show that this assertion was not itself demonstrable by the arithmetical manipulation of Godel Numbers The importance of this proof is that arithmetical reasoning is shown to be insufficiently powerful to demonstrate its own consistency; the possibility is, however, left open that the consistency of mathematics might be demonstrable in terms of a non-mathematical meta-language

There is an interesting psychological application of the second of these two proofs When the attempt is made to prove the absolute consistency of a formal calculus in terms of a meta-language which obeys the same dogma as the calculus itself, the situation is similar to that of a man who attempts to calibrate one instrument, such as a ruler, against another from the same factory The best that can be hoped is that the measurements made by the two instruments will lend each other support, for, when they disagree, neither can claim the final authority If we accept that human reason is incapable of achieving a watertight proof of its own rationality, even in the strict language of formal logic, the same must apply still more forcibly to reasoning carried on in the far less precise and stable language which we ordinarily use, unless we relinquish the hypercritical standards of absolute proof which logicians demand The critical evaluation of one's own reasoning, in short, is probably quite as fallible as the reasoning itself, and "second thoughts" no more reliable than "first impressions"

If it is correct to argue from the particular case of mathematics in this way, then when a man analyses a possible flaw in his own thinking, he is indulging in what might be called "meta-thinking" and the result is liable to be a deadlock unless either he is prepared to be content with something less than certainty, or he is capable of greater rigour in his meta-thinking than in his suspect first thoughts We know that this type of deadlock can occur and may reach pathological dimensions, the perfectionist is very prone to lapse into obsessional doubt, to demand absolute certainty and to ruminate ceaselessly on one topic or another It is perhaps also relevant that one symptom of the severe anxiety to which obsessionalism can lead is the fear that reason may be completely lost The analogy with "inconsistency" needs no underlining

From a therapeutic standpoint these considerations suggest that such people may be helped, in general, by whatever gives them the confidence to accept a degree of uncertainty—whether this agent be a pharmacological euphoriant or some kind of reassuring relationship Indeed, we do find that obsessional people tend to seek a father-figure Another approach should theoretically be the introduction of a fresh meta-language, capable of greater rigour than either the first thoughts or the critical second thoughts of the patient, in other words, someone who will do his meta-thinking for him This interlocutor would have to be of higher intellectual discrimination than the patient and free from the particular preoccupation which besets him, he would then be in a position to redefine the problem and to throw his weight on one side or the other

In practice the necessary "third language" is often provided by an established source of formal dogma covering the main area of conflict, whether it be religion, politics, sex, or some narrower topic A dogma relieves the victim of any need to decide and may liberate his mind for other pursuits, but for this recourse to be available to the patient the source of dogma must be acceptable It may be that the occasional effectiveness of analytical psychotherapy in relieving what are, in effect, deeply buried obsessional pre-occupations ("conflicts") depends upon a combination of two simultaneous processes—on the one hand the gradual eliciting of material and the analytical breakdown of the patient's problems to a few central issues, and on the other, the cultivation of a transference relationship which establishes the analyst as an acceptable source of dogma on these issues

The psychological analogy with Godel's work provides a crumb of comfort for those who occasionally doubt their own sanity It will be remembered that in the first of his proofs, the alternative to mathematics being irrational and inconsistent was that it must be incomplete Godel himself regarded this second alternative as meaning that mathematics was an inexhaustible field for empirical discovery, and it is consoling, surely, to feel that one can interpret one's state of mind at such times either as insanity or as intellectual fecundity

In England Now

A Running Commentary by Peripatetic Correspondents

As I approached the group of five-year-olds, I could see that they were in a state of anxiety and excitement One of them, Samuel, was near to tears At their side Samuel's large dog was happily eating my sandwich lunch " Quickly, quickly," cried a little girl, " the dog is eating your sandwiches " And Samuel added his plea, " Hurry up, Mister, white bread is bad for him "

* * *

I have lately received a number of inquiries which show that in these days of crowded resorts and high fares the hospital holiday is becoming increasingly popular Many people, I know, look with disfavour on surgical operations, though in my opinion this is generally based either on misconceptions or on deliberate misrepresentation by selfish addicts who fear to see their own pet preserves invaded I myself have always found a visit to one of our justly famous hospitals a very pleasant change

Last year I hesitated for some time between a festival of modern music, an undoubtedly attractive tour organised by a botanic garden expert, and one of the big peace marches, but recalling the delights of previous experiments in this somewhat lesser-known field—the nurses, the flowers, the grapes, the hours of leisurely reading—I found myself once again unable to resist the call of the clinic

Here let me sound a note of warning Just to decide upon any operation, without paying due attention to the enchanting alternatives offered, is equivalent to saying " I'll go to Italy " instead of " I'll go to Cannobio or Torri del Benaco " And I am sure I shall hurt no surgeon's feelings—and it is my considered opinion that no body of men has done more for the tired business man than our surgeons—when I remind readers that, just as there are hospitals and hospitals, what may be suitable for one man may prove disappointing to another Indeed, there are as many fascinating facets to the relinquishment of superfluous parts of the human body as there are lakes in Italy and Switzerland, or forms of Roman or Florentine architecture I heard, for example, of a chartered accountant who, wanting just a short break from an arduous but lucrative practice, made the mistake of choosing an incision instead of an excision His disappointment was intense, and he returned to his office feeling little better for the change True, the holiday was not a total loss there was the initial anæsthetic—that delightful moment equivalent to the first trembling of the boat beneath one's feet or the sight of the trees falling away as the plane takes off—but the exhilaration of awakening from deep sleep to find that yet another unwanted oddment of the body had been sloughed off was lacking

The wise man will select his hospital as carefully as his operation, and here let me say that it is no longer necessary to confine oneself to the better-known resorts The large and fashionable establishments such as Guy's and Barts naturally offer a wider range of exciting and even novel possibilities, and are, of course, famous for their varied choice of anæsthetics, but many smaller and less-known hospitals cater for the discerning visitor who prefers to go somewhere more off the beaten track, and at a price to suit even the slenderest purse I know of one small and unpretentious establishment within twenty miles of London which will do an all-in appendectomy for very little more than the cost of a visit to Glyndebourne

Few who have not experienced this type of rest cure can realise to the full the amenities of hospital life At what hotel, for example, are *all* meals served in the bedroom without extra charge? At what hotel will the chambermaids uncomplainingly make your bed while you are still lying in it? At what hotel will that same bed be moved in fine weather on to an airy balcony, or two creamy arms raise you carefully on your pillow when you wish to read and lower you as tenderly back when you wish to sleep?

I fear I may be taken to task if I fail to point out that many hospitals are as yet unlicensed, though an occasional glass of brandy can, I am told, be obtained by those who know the ropes In my opinion, however, this point is of less importance than might at first appear I have already referred to the variety of anæsthetics available to guests in most of our hospitals, and a wide choice of out-of-the-way beverages is to be found in the cellars of the more select houses, and I have yet to meet the connoisseur of fine drinking who, once he has discovered the fascinating bouquet and colour of some of the really great prophylactics, will willingly revert to his former tastes

One last word of warning Though hospital holidays are not yet fully commercialised, more and more people possessed of the pioneering spirit are becoming aware of their possibilities, so that already a certain amount of advance organisation is necessary Inquiries can be addressed, through your own local agent, to any reputable specialist

* * *

When I start to do a barium meal I usually like to get some grasp of the patient's complaint with the help of a few opening questions about gastrointestinal symptoms The replies are varied, often irrelevant, and often at variance with the history which has been elicited by another consultant in the outpatient department, though not necessarily on that account any less accurate Perhaps the most unkind reply, however, was " I have had everything wrong that my doctor can think of, so he sent me along here for an X-ray "

* * *

It is all very well to bemoan the pædiatrician's burden at Christmas, but has anyone given a thought to the burden of the psychiatrist in a mental hospital?

It was the Medical Superintendent's idea " All part of the open-ward policy," he explained " Father Christmas means freedom for millions A visit from him, more than anything else, will show our chronic patients that they're free to come and go as they please And you, Smith," he paused and looked at me, " will be Father Christmas "

On the day I was dressed up, given a large gin and, to the accompaniment of raucous cheers from people I had hitherto regarded as friends, started my round At the first ward the patients were all gathered in the entrance hall None of them took the slightest notice of me, despite the nurses' attempts to stir up excitement I left quickly for the next ward, my spirits rising as I calculated that I ought to be back in the mess in a quarter of an hour This shows how fatal it is to make predictions, for in the next ward I met someone who really was Father Christmas He was seething with rage at the idea of being impersonated. He told me that he was the one and only Father Christmas and that I was almost everything under the sun except Father Christmas I was so alarmed that I stepped backwards and, tripping over my gown, fell on my back. For one dreadful moment I lay helpless Then I had one of those rare moments of inspiration " Your Majesty," I babbled from beneath my beard, " I am not Father Christmas In fact I have come especially to find and escort you round the hospital The reindeer have been delayed, but we can walk "
It was four hours later before I got back to the mess

Father Christmas is a changed man and the Medical Superintendent hopes to discharge him home shortly As for me, I'm thinking of emigrating to one of the less progressive countries before next Christmas

* * *

The other day I used the word " carminative " and was promptly asked by a member of my family whether I was referring to one of the B M C. new baby cars

NATURAL HISTORY OF CAVERNOUS HÆMANGIOMATA

SIR,—Having for some years made a practice of carefully observing infantile cavernous hæmangiomas, and having rarely undertaken any early treatment for these lesions during this period, I am surprised at Mr Denis Browne's strictures on Dr Simpson's article (Dec 12) It is my practice to explain to the mother the facts about the natural resolution of the majority of cavernous lesions, if necessary to show her photographs of cases in which this has occurred, and to ask for her cooperation in regular observation of the baby In my experience the mothers are happy to follow this course, and on only one occasion has a baby subsequently been taken elsewhere (in this case to a radiotherapist who treated the lesion) I have found that, despite early enlargement of some of these hæmangiomas during the first six months, the ultimate results have generally been most satisfactory Residual lesions can be excised if necessary but it is unusual for the final condition to warrant this

Dr Jones states that statistics can be misleading and that large numbers must be studied It is a common fallacy that "large numbers" add to the validity of observations whereas the careful observation of small numbers of strictly comparable cases is often far more rewarding The figures quoted by Dr Jones are certainly rather confusing Thus, at the Presbyterian Center, New York, it is stated that 135 out of 584 patients with cavernous hæmangiomas were untreated, and Dr Jones seeks to compare these with Dr Simpson's 170 lesions of which 140 were untreated I would submit that it is unwise to attempt to compare the two series However, if one is seeking information about the natural history, Dr Simpson's series (in which 82% of lesions were not treated) should be more informative than the American series in which only 23% of patients were untreated Dr Jones includes reference to 329 patients with hæmangioma simplex in the American series, but Dr Simpson's paper was not concerned with this type of case

Dr Jones goes on to refer to 814 out of 1752 "angiomas" (were these all cavernous?) which received X-ray therapy in Sussex and Kent He states the criterion of recovery but gives no information about the results achieved, or when the improvement occurred It is implied that a number of cases had repeated treatment and it is plain that almost 25% were still being treated after a five-year period Dr Jones also states that only 20% cleaned in the first year I must confess that I find it impossible to gain any precise idea of the Kent and Sussex results referred to by Dr Jones though I gather that he regards the cosmetic result as better in the treated cases

I have read Dr Simpson's paper with care and, as a surgeon, I find little with which I disagree In his discussion he makes it perfectly plain that residual lesions can be better treated at a later date, but his brief summary gives a slightly misleading impression of his views in that it baldly concludes "no treatment is necessary"

London, W 1 REGINALD S MURLEY

LEAF PROTEIN AS HUMAN FOOD

SIR,—It would be superfluous to say that Mr Pirie's proposals for the use of leaf protein as human food (Nov 28) are highly commendable and deserve success but there are blemishes in his argument that should be removed

He stated that "it is likely that a deficiency of any aminoacid in one protein (in leaf) will be compensated for by the other proteins, so that there will be no extensive deficiencies or excesses in the mixture" Likely perhaps, but, unfortunately, not true

Cabbage protein[1] contains less than 50% of the isoleucine, leucine, S aminoacids (i e, methionine+cystine), phenyl alanine, and valine of egg protein, which can be regarded as the standard Kale contains less than 50% of the isoleucine, lysine, and S aminoacids, mustard greens less than 50% of the threonine, isoleucine, leucine, S aminoacids, and phenyl alanine, sprouts less than 50% of the isoleucine and leucine of the egg standard These analyses are supported by biological estimations on cabbage protein[2] and two fractions of grass protein[3]

The primary requirement of a protein supplement for human feeding is a high content of methionine and cystine as most human diets are limited by this pair of aminoacids[4] Leaf proteins make no major contribution to this demand The isolated proteins of lucerne[5] contain 50% of the methionine-cystine of egg, 60–70% clover, 55% groundnut leaves, 50% barley grass protein

The experiment on pigs quoted by Mr Pirie, showing that leaf protein was as good as fish meal, was supplementation of a cereal ration in which lysine, not methionine, was limiting Further, the level of protein fed was too high to reveal possible differences between leaf protein and the fish-meal control (Moreover, fish meals can range from poor to good as proteins go)

These limitations are set out not to abolish but merely to reduce the height of the hopes set on leaf protein

This said, there remains the enormous problem of presentation Mr Pirie speaks of British prejudice to the green colour, but prejudices are worldwide and difficult to overcome In Guatemala the protein intake has been substantially increased in an acceptable way by adding cottonseed-maize to the local gruel This procedure is not acceptable across the border, because the supplement imparts a slight colour to the food This would suggest that no efforts should be wasted in offering leaf protein to verdophobes but only to such areas where the colour is considered advantageous

What is needed is a good cook/chemist/home-economist to produce an edible finished product that suits local custom and thus becomes acceptable

Bovril, Limited,
London, E C 1 A E BENDER

SIR,—Mr Pirie's reply (Dec 26) to the letters of Dr Cicely Williams and Mr Allen deals effectively with their criticism, and clarifies a number of the details mentioned in his original article The problem of getting enough food is a desperately serious one to millions of people, and it is encouraging to see basic research directed towards its solution There are a couple of points which have been raised in the present discussion which seem to me to merit amplification

The first is the question of the nutritional value of leaf protein Mr Pirie states that for pigs, chickens, and rats the protein extracted (from English leaves) is as good as, or a little better than, fish meal, "though not as good as the pre-eminent proteins—casein and egg albumin" If this is found also to be true for human children and tropical leaves, it will be good news for those areas where there is a deficiency of total protein

4 Miller, D S, Dema, I S *Proc Nutr Soc* 1958, 17, i
5 Proteins in Foods Indian Council of Medical Research, 1958

in the diet. However, there are many areas where the dietary intake of protein appears to be adequate but signs of protein deficiency still abound, and it is found that the protein is almost exclusively of vegetable origin In Uganda, for instance, there is an impressive amount of kwashiorkor, and of the milder form manifested by retardation in growth, but recent experience with distribution of skim milk powder[1] showed that even those children who received a relatively small amount (well below the amount currently recommended by UNICEF) showed a substantial improvement in weight gain. The proceedings of the Third Inter-African Conference on Nutrition[2] bear witness to the need for further investigation of the nutritional status of groups consuming different proportions of foods of animal and vegetable origin, and this was emphasised in the recommendations of the conference In her admiration for Samuel Smiles, Dr Cicely Williams may be contemptuous of "the teaching propounded by foreigners, who have spent most of their time concentrating on the virtues of skimmed milk", but virtues cannot be lightly ignored, even if propounded by foreigners Self-sufficiency, particularly in the production of foodstuffs, may seem elementary good sense, but I have the impression that economists are all in favour of trade, and there appears to be plenty of scope for trade in skim milk powder—if only the powers-that-be would develop it.

The other point, a small one, springs from Mr Pirie's observation that there is room for improvement in the varieties of vegetables grown in the tropics Indeed there is, and for passing on the knowledge to local farmers At present, economic interests being what they are, tropical plant breeders are occupied almost exclusively with improving cash crops—cocoa, cotton, coffee, &c.—and with making these available to farmers Even where better varieties of food crops have been bred (as with maize at the Cotton Research Station in Uganda) no effort is made to encourage their use by farmers Here again there is scope for action by the powers-that-be.

The National Hospital,
Queen Square, London, W C 1

JOHN MCFIE

SIR,—Are not Mr Pirie (Dec 26) and Mr Allen (Dec 12) both partially correct? Of the nutritive value of leaf-protein there would appear to be no doubt, but as a processed food for human consumption would there not be many difficulties?

The essential reason for malnutrition, certainly as one saw it in the 1930s in Southern Nigeria, was poverty The same period coincided with the effects of a world economic slump which led to a prolonged and catastrophic fall in local produce prices

While recognising that certain basic dietaries in parts of Nigeria are much more vulnerable than others, one must appreciate that millions of Africans live a normal healthy life, supplementing their own dietary Any new food concentrate would have to have a very special appeal and be available to those most needing it without extra cost.

Actually the introduction of what is essentially a protein supplement would not be new to Nigeria. I understand that attempts are now being made to popularise 'Food Yeast' My own experience was with 'Marmite', and the demand for it later became so great as to far exceed its therapeutic use. Its success depended on (1) as a therapeutic agent it was dispensed free, (2) it had a visible effect on what was then a very prevalent condition, (3) its palatability appealed to those otherwise dependent on a predominantly vegetarian diet, and (4) it did not offend dietary custom or habit.

I also used a large amount of dried brewer's yeast. Though effective therapeutically, its taste made it unpopular

I doubt whether a protein leaf concentrate would achieve any direct objective On the other hand, provided costs permit, it could be supplied to animals and thereby be an indirect source of food.

Parkstone Dorset.

TREATMENT OF BLEEDING PEPTIC ULCER

SIR,—Blind gastrectomy has saved and will save many patients who would otherwise die of hæmorrhage We must stop the bleeding without exhausting the patient's reserves By all means let us try any promising method, such as that quoted by Mr Downie (Dec 12) But once it is clear that operation is necessary a determined policy must be pursued This means rapid replacement of blood, and operation within two hours of the decision to operate

When the abdomen has been opened the following rules will help young surgeons who have to do the bulk of this work.

(1) Exclude portal hypertension

(2) Rapidly examine the upper jejunum for contained blood If present, bleeding is active and there is need for haste If absent, examine the ileum. Blood within often means that bleeding from the upper alimentary tract has temporarily ceased and there is more time for search.

(3) Inspect and palpate the proximal duodenum and the whole of the stomach. The left hand is the more useful Open the lesser sac with the forefinger and middle fingers above the stomach and palpate the back of the stomach An irregular fatty patch with irregular vessels near the lesser curvature on either surface indicates an ulcer If the stomach contains much blood, open it at once. Remove clots manually and fluid with the sucker (Twice in one week I found large holes in the splenic artery from ulceration on the back wall of the stomach, far to the left.)

(4) If no obvious source of bleeding is found re-examine more thoroughly the whole of the small bowel, looking especially for such lesions as the hæmangiomata described by Mr Lytton (Dec. 26) and Mr Read (Jan. 2), or an ulcer in a diverticulum.

(5) If no bleeding point or ulcer has been found do not make further search in the stomach but do a two-thirds Polya gastrectomy In the course of this the bleeding point may become obvious, as for instance a small ulcer on the postero-inner wall of the duodenum. The crater may be seen in the open duodenal stump, or the artery (usually a short branch of the anterior pancreatico-duodenal) may be seen spurting while the duodenum is being cleared.

After operation examine the excised stomach, slitting up the greater curvature. The bleeding point may sometimes be found on holding the specimen up against the light. Mark any suspected area with a black silk stitch as a guide to the pathologist.

With such a policy, a few stomachs will be needlessly sacrificed but many lives will be saved

Edgbaston,
Birmingham.

FAUSET WELSH

SIR,—The discussion provoked by the two articles on hæmatemesis (Dec 5) raises the important issue of selection of patients for operative arrest of the bleeding There is little doubt that a policy of selective surgery is effective in lowering the mortality from hæmorrhage provided that an early decision is reached in suitable cases Early identification of the lesion responsible for bleeding is of great importance in this connection so that patients with recurrent hæmorrhage from chronic peptic ulcers can be operated upon without delay

At the Central Middlesex Hospital we have attempted to meet the need of early ætiological diagnosis by a combined procedure of immediate gastric aspiration (for pH analysis), followed the morning after admission by gastroscopy and shortly thereafter by barium-meal examination done on the ward using a portable X-ray apparatus Of the last 150 admissions for hæmatemesis correct diagnosis has been achieved in 80% by this method, usually within 36 hours of admission. The possession of information of diagnostic value as to the cause of illness in circumstances of recurrent bleeding greatly assists the often difficult choice between operative and conservative treatment Indeed, in the last week during a surge of peptic activity in north-west London, 6 patients have undergone emergency gastrectomy for bleeding in this hospital, and in all but 1 patient, whose restlessness prohibited investigation, the decision to operate was undertaken with foreknowledge of the responsible lesion 4 of these patients were bleeding from chronic gastric ulcers, a group in whom surgical treatment is particularly indicated

The importance of reaching an early decision between surgical and medical treatment of bleeding peptic ulcer cannot be overemphasised, for rapid deterioration despite apparently adequate replacement of blood by transfusion *is common and delay in seeking surgical aid too often fatal* It is our experience that the procedure of early investigation is both informative and harmless and is an important factor in the successful management of patients bleeding from an unknown lesion in the gastrointestinal tract

Though full investigation by pH analysis, gastroscopy, and early X-ray examination may be impracticable in most hospitals, we have found that ward barium-meal examination using the portable X-ray machine gives diagnostic information in more than three-quarters of patients admitted after hæmatemesis This simple radiological procedure is well within the scope of a general hospital The detailed technique will shortly be published

POSTCOITAL EXAMINATION OF SEMEN

SIR,—For the past twelve years I have, with few exceptions, referred all husbands of my infertile couples to Dr Davidson (Jan 2)—several hundred of his 12,000 cases From my personal experience I can say that Dr Davidson's direct semen examination has "saved many women a great deal of unnecessary investigation, discomfort and eventual frustration" The majority of subfertile men can be improved

I can endorse everything Dr Davidson has said in his letter

Croydon

ARTHUR CLIFT

DENTISTS AND ANCILLARIES

SIR,—I must point out that Mr Markham (Dec 5) failed to stress the fact that insufficiently trained persons will be practising on *the youth of this country if dental* ancillaries are in being

Your remarks about the apparently unattractive nature of the work of a dentist seem contrary to the fact that some hundreds of applicants all over the country are being turned away annually by the dental schools In the House of Commons, Mr Walker-Smith admitted "*As a matter of fact there is no shortage of recruits to* the dental profession at the present time" He did not think inducement grants were needed "It is really a matter of accommodation, and we are getting on as fast as possible"

Surely the public, and in particular the children, are entitled to dental treatment by fully trained and qualified dental surgeons 38 years after the 1921 Act we still see the results of unskilled treatment, and while the dental surgeon of today is doing his best in his overcrowded day, the Government, apparently with your approval, is going back half a century

Does the medical profession not realise that this dilution of the dental profession is not in the interest of either the profession *or the public, it is Government chicanery to attain cheap* dentistry, and the shortage of dentists is being put to good use

The medical profession is being abused because of possible overcrowding Were there a shortage of doctors, I wond what type of ancillary would be introduced

Instead of quarrelling about the fact that young dentists by hard work and long hours can earn professional remuneration, while young doctors are being exploited, as complementary professions each should be understanding of and sympathetic to the other and work together for their mutual benefit

If the ancillary experiment is a success and I have no doubt that it will be, we shall see the beginning of the end of dentistry as a profession and a distinct fall in the standard of dental treatment If the new ancillary training hospital at New Cross was to be used for the training of dental surgeons, and if the project Mr Walker-Smith has in hand of admitting 900 dental students per annum was speeded up, there would soon be no shortage of dentists

London, N W 7

M CHALMERS

CLASSIFICATION OF CHRONIC BRONCHITIS

SIR,—Your annotation of Dec 19 rightly draws *attention to the necessity for an agreed nomenclature in* regard to the clinical condition which, *in this country*, is traditionally called "chronic bronchitis" At present we are largely ignorant of the natural history and causes of this disease, so that any classification to be generally acceptable must be simple and based on easily distinguishable clinical features Fletcher's excellent classification,[1] to which you refer, points the way, but is too elaborate for widespread use If kept to its three broad categories, it is a useful basis from which further subdivisions may be made

The first type which Fletcher has called "simple chronic bronchitis" would surely be better termed "bronchorrhœa" This avoids the suggestion inherent in the word "bronchitis" that the process is inflammatory, and so far as I can ascertain from medical dictionaries, *simply means "an excessive dis*charge of mucus from the air passages of the lungs", and has no other connotation

Fletcher postulates infection as the dominant feature of his second type It may be only pedantic to argue that mucopurulent sputum, or recurrent chest illness, is not always evidence of infection, but certainly there is a difference between the hearsay evidence of the patient reporting thick yellow phlegm, and the *physician actually observing* purulent sputum, just as there is a difference in the readiness of different patients to admit to "recurrent chest illness" Nevertheless, it is this second stage of bronchitic disease which is likely to be the most important clinically during the next few years, and an acceptable classification could *usefully postulate the objective* observation of the patient's purulent sputum

Until recently, any definition of ventilatory impairment has been *difficult because subjective appraisal* differs widely. Fortunately, Wright's peak expiratory flow-meter now affords a means of evaluation of ventilatory capacity which can be measured easily and quickly in any hospital outpatient department, and a peak expiratory *flow-rate* of, say, less than 300 litres per minute could be *arbitrarily accepted as a definition* of moderate ventilatory impairment in a bronchitic subject

The three stages of bronchitic disease might therefore be *(1) bronchorrhœa*, *(2) recurrent infective* bronchitis, (3) recurrent bronchitis with ventilatory impairment All these can, of course, be subdivided

If some responsible body closely associated with research in this field arbitrarily ventured to postulate its definitions, it might be a considerable encouragement to *individual research-workers to publish their findings* in terms of such definitions which would facilitate the comparison of published work

PYELOGRAPHY IN URINARY INFECTION

SIR,—" Pyelography not yet justified " This statement in Dr James' article (Dec 5) prompts me to ask again when is pyelography justified in renal-tract infections? While R M O at Salisbury General Infirmary recently, I included intravenous pyelography as a routine investigation in all acute renal-tract infections amongst the nursing staff The total number of such cases was quite low but, to my surprise, three pyelograms revealed evidence suggestive of obstruction in two there was persistent unilateral ureteric kinking and in a third a double ureter was shown on one side As these were all first infections in otherwise healthy young girls surgical intervention was not sought I am still wondering whether this was the correct attitude or not

There is a wealth [1] [2] of experimental and presumptive clinical evidence showing a correlation between obstruction and renal-tract infection Of the possible permanent sequelæ to such infection we are only too well aware That obstruction was a possible factor in the pathophysiology of these cases I had little doubt Yet I am sure most surgeons would be loathe to intervene in the absence of more positive evidence, such as persistent or recurring infections, or calyceal distortion Logic teaches that this is obviously too late and that many cases of occult persistent infection will be missed Nevertheless until we are prepared to investigate and treat actively all cases of " minor " anatomical disturbance I see little point in routine pyelography I wonder does Dr James think likewise?

Dublin

JAMES G DEVLIN

TROPHOBLAST AND ITS TUMOURS

SIR,—If the trophoblast is a homograft, the full implications do not appear to be yet realised Surely if tolerance to a homograft can be induced in a fœtus or newborn animal, but not an adult animal, by injection of donor cells it is an unjustified extrapolation to suggest that a similar mechanism occurs in the human adult pregnant female host This topic is not new, in your columns I pointed out ten years ago [3] in detail the inconsistencies that the present hypothesis leads to and suggested an alternative The alternative is that the trophoblast is an autograft, at least the syncytial portion of it, and derived from the granulosa cells that cover the ovum when it leaves the follicle

Unorthodox as this suggestion is it at least makes sense, which the present orthodoxy does not I suggest that the main function of the syncytium is to protect the fœtus from the homograft reaction of the mother, and perhaps vice versa to protect the mother from the fœtus Remember that however separate the fœtus may be from the mother the syncytium is as intimately involved in the maternal circulation as any cells can be

MATERNAL INFLUENZA AND CONGENITAL DEFORMITIES

SIR,—The article by Dr Coffey and Professor Jessop (Nov 28) merits further comment, especially in view of two contradictory reports on this subject In all likelihood, these reports were not available to Dr Coffey and Professor Jessop when they completed their study

Wilson and his co-workers as a result of their investigation [1] concluded that " No significant teratogenic effect of Asian influenza was demonstrated " It is to be noted that the presence or absence of influenza in the patients they studied was confirmed by hæmagglutination—inhibition titre determinations

Walker and McKee [2] have concluded that " there was no apparent alteration in the number of anomalies in the infants of mothers who had Asian influenza during their pregnancy" In this study serological tests for influenza similar to those employed in Wilson's investigation were also carried out

On the basis of the findings of Walker and Wilson one might well question the implications of the Dublin study Moreover, the methodology of selecting patients for inclusion in the study on the basis of self-diagnosis is vulnerable to criticism This is so, not so much (in this instance of a disease with a high attack-rate) because those replying in the affirmative may not have had the disease, but, as Walker's study points out, because those replying in the negative may very well have had the disease

FORMATION OF RENAL CALCULI

SIR,—I was very interested indeed to read your annotation of Oct 24

I have been carrying out a small experiment to try to confirm or refute the claim that the administration of salicylates prevents the formation of urinary calculi

Medo-Chemicals Ltd have very kindly supplied me with a stock of their ' Salimed ' tablets and also some pseudo-salimed tablets, and I have been administering these to an unselected group of patients who have had recurrent urinary calculi, but in whom there is no local predisposing cause to recurrence, such as chronic infection or stasis This is obviously a very long-term type of investigation and as yet it is not possible to draw any conclusions

I know that claims have been made in America, both for and against its administration, but I feel that both these investigations were not sufficiently selective or continued for a sufficient length of time to justify the conclusions I hope in a few years' time that I shall be able to give some results which may help to decide whether there is any value in the administration of salicylates, or salicylate-containing substances, to patients with recurrent calculi

Hove, Sussex

S H C CLARKE

ÆTIOLOGY OF LEUKÆMIA

SIR,—The theories discussed in your leading article [3] on the ætiology of leukæmia are intriguing However, some results of our studies on human leukæmic leukocytes in vitro are in disagreement, not only with the concept of chronic leukæmia as a conditioned neoplasm resulting from deficiency of a blood-borne growth inhibitor but also with the thesis that autonomy of leukæmic cells (i e, in acute leukæmia) might be specifically indicated by an abnormal chromosomal pattern We failed to find any chromosomal abnormality in the three cases of *acute* granulocytic leukæmia reported some time ago,[4] and more recently we have found a small, but definite, abnormality, a minute replacing one of the 46 normal chromosomes, in the 2 cases of *chronic* granulocytic leukæmia investigated [5]

EMERGENCY RESUSCITATION IN RUPTURED ECTOPIC GESTATION

SIR,—The problem of inadequate sources of blood for replacement after massive hæmorrhage is probably the main bugbear of surgery in many hospitals overseas Fortunately, as Mr Azie points out (Dec 12) in the patient with ectopic gestation we have adequate blood reserves available—her own

In this hospital the patient is sent immediately to theatre, and a drip started Anæsthesia takes no longer than adequate scrubbing by the surgeon, and saves the patient from the added shock of seeing her own blood being, as she thinks, sacrificed

Through a small nick in the peritoneum a fine "sieve"-ended cannula is inserted into the cavity and the free blood drawn into sterile citrated bottles while adequate exposure is made in the more superficial layers This decompresses the abdomen and minimises blood wastage The blood collected is returned to the patient through the drip at maximum speed, the first litre being given in 5 minutes The subsequent rate is controlled by the patient's condition The blood-bottle filters seldom show clot, and we have now records of over fifty cases without mishap, and up to 2 litres of peritoneal blood have been given

Theoretically, this technique is open to objections, but to those of us who serve on the frontiers of medicine the consistently good result justifies its use We have tried the collecting, whipping, straining, and reinjecting methods and have rejected them in favour of a technique as safe as it is simple The patient is back in bed within half an hour often apparently little the worse for her experience, except for the loss of her tube

Finally, Sir, may I express my appreciation of the fact that your highly scientific journal finds space for the description of techniques which, though unnecessary in highly developed countries, may still save many lives in less fortunate areas

J ASHFORD HYDE

SIR—I was interested in the recent letters from Mr Azie (Dec 12) and Prof Chassar Moir (Jan 2) on emergency resuscitation by the use of the patient's own blood removed from the abdomen and think it may be of interest to record an early instance of the use of this method

In the spring of 1915 at Bethune I saw Capt John Fraser (later Prof Sir John Fraser) use blood removed from the abdomen of a man suffering from a gunshot wound, for transfusion after filtration through silk I do not know whether this was ever recorded elsewhere but at that time, when blood for transfusion was unobtainable, the method was regarded as unique

CLAUDE FRANKAU

URINARY INFECTION IN THE NEWBORN

SIR,—I am grateful to Dr Brown (Dec 19) and Dr McNicholl (Jan 2) for their comments on my paper of Dec 5 I regret that the pus-cell counts were omitted and they are given in the accompanying table

—		Growth of organisms			
		Sterile	Scanty	Moderate	Heavy
No of cases		4	82	9	5
Pus-cell count	Males		141→10 750→20 Others less than 24	10 138→10	27 1000→18,000 1000→1150 1000→1700
	Females	Less than 33	Less than 40	108→24 261→52 Others less than 32	11

I agree with Dr Brown that the criteria for diagnosis must be carefully assessed, and for this reason I stressed that the cell-counts in the urine must be repeated in cases of doubt, especially where there is lack of correlation between cell-count and culture He will also see that a second count is recorded in the chart reproduced in my paper

I have observed that the incidence of neonatal urinary infection varies from time to time in the same maternity unit even when constant criteria are used for diagnosis, but for this I can give no explanation

Pus-cell counts in a measured quantity of uncentrifuged urine can be reported with accuracy and results are comparable from any hospital or laboratory, whereas microscopic field counts must vary according to the size of the drop held by the coverslip

Stansfeld [1] reported that an average of 1 pus cell per high power field was approximately equivalent to 250-500 pus cells per c mm of uncentrifuged urine It is therefore evident that this method of urine examination is unsuitable for demonstrating urinary infection in newborn babies

I am most interested in Dr McNicholl's report of hæmolytic anæmia associated with renal infection I have had 2 similar cases, but in each of them the blood culture for *Escherichia coli* was positive I have observed no other cases

London, W 1
URSULA JAMES

PRISONS

SIR—Your leader of Dec 5 rightly applauds the work of the prison service in the face of an increasing prison population, but makes no mention of the appalling physical conditions existing in some prisons today Improvements in the prisoners' uniform and relaxation of the "silence" rule in workshops can only partially alleviate the problems posed by buildings which are frequently over a hundred years old, inadequately heated, and provided with sanitation barely fit for animals

An offender is sent to prison *as a punishment* and not *for punishment* [2] As you have stated, many youths wait for two months in local prisons before reaching reception centres It might usefully be pointed out that, because of the rapidly changing population, the cell blocks in which they are housed (e g, at Wormwood Scrubs) are actually in a worse state than those housing the more permanent adult prisoners The stench of urine in these blocks is overpowering It is a sorry thing that those in authority are apparently as impervious to these facts as the prison walls to the heat of a summer's day

HIRSUTISM AFTER ADRENALECTOMY

SIR,—I was very interested in the report by Professor Bruce and his colleagues (Dec 12), who noted vigorous facial hair growth after bilateral adrenalectomy and gonadectomy

Thomas and I, in a study of some 600 patients,[1] found an increase in facial hair growth and disappearance of hair from the lower abdomen with advancing years Gallwey and I, in a further unpublished study of about 400 patients, confirmed this and found a similar disappearance of hair at eight other sites Clearly facial hair behaves differently from hair elsewhere after the menopause, some factor peculiar to this area must be presumed The observations of Strong, Bruce, and Falconer suggest that this is non-hormonal, though a release from hormonal influence may be involved.

DAVID FERRIMAN

TREATMENT OF INOPERABLE CANCER WITH 5-FLUOROURACIL AND IRRADIATION

SIR,—Curren et al [2,3] have shown that the administration of 5-fluorouracil, a pyrimidine antagonist, produces significant objective improvement in an impressive number of patients with far-advanced metastatic neoplastic disease The most favourable results were in carcinoma of the breast, ovary, large bowel, and rectum, and in hepatoma Variable responses were noted in a number of neoplasms, including carcinoma of the cervix No response was obtained in carcinoma of the lung, stomach, pancreas, and kidney, and in a variety of other tumours, including embryonal-cell carcinoma of the testis Tumour regression was observed only in patients treated to a toxic level Toxicity was characterised by stomatitis and diarrhœa, and later by suppression of hæmatopoiesis, and severe toxicity by ulcerative lesions in the alimentary canal

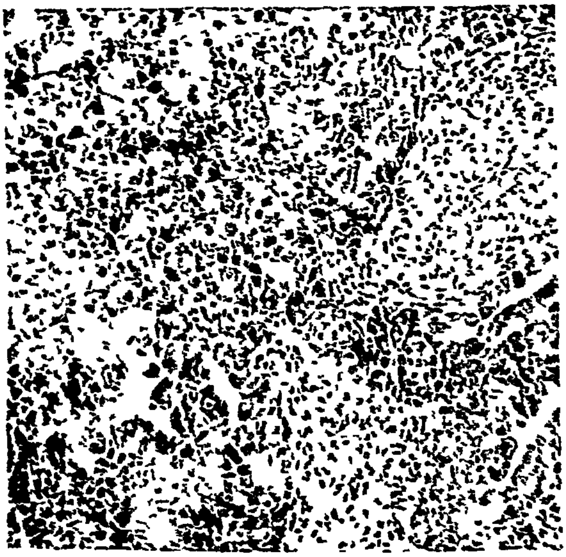

Fig 1—Embryonal-cell carcinoma

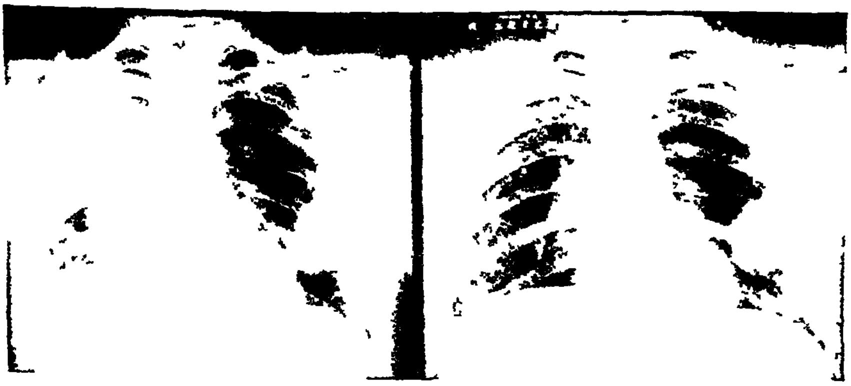

Fig 2—(a) Chest radiograph before combined treatment (March 20), (b) after treatment (May 12) with 5-fluorouracil and irradiation of right hilar mass.

In the hope of avoiding moderate to severe toxicity, we decided to administer 5-fluorouracil in sub-toxic doses concomitantly with deep-ray therapy

Initially, patients with inoperable carcinomas of the head and neck and of the lung were selected for combination therapy Subsequently, other types of malignant disease have been treated by this means also Treatment consisted of the intravenous administration of 5-fluorouracil throughout the period of irradiation, except in isolated instances when 5-fluorouracil therapy was discontinued temporarily because of manifestations of toxicity (stomatitis, diarrhœa, or leucopenia) The dosage was as follows 15 mg per kg per day for 4 days, 7 5 mg per kg on the fifth day, and thereafter 7 5 mg per kg twice weekly until the course of irradiation had been completed

In 3 patients with undifferentiated squamous-cell carcinoma of the lung, in 2 patients with pulmonary metastases secondary to embryonal-cell carcinoma of the testis and to adenocarcinoma of the rectum, and in 1 patient with lymphoepithelioma, 5-fluorouracil and X-ray therapy were stopped when a radiation (tumour) dose of 2000–2250r had been given. Chest films were taken before and two weeks after completion of therapy All other patients in our series received larger doses of radiation than those mentioned above

All the patients who received 2000r plus 5-fluorouracil showed rapid and significant regression of their lesions except for the patient with pulmonary metastases secondary to adenocarcinoma of the rectum These observations suggest that either there may be an additive effect when the two treatments are used simultaneously or that one method may potentiate the anti-tumour effect of the other Since 5-fluorouracil alone in carcinoma of the lung did not produce tumour regression in the cases of Curren et al, and since a tumour dose of 2000r administered alone rarely produces a significant response in this type of tumour, it is possible that 5-fluorouracil actually increases tumour radiosensitivity

To date, excellent initial responses to combined therapy have been observed in 6 of 8 squamous-cell carcinomas of the lung, in 4 of 5 squamous-cell carcinomas of the head and neck, and in 1 patient each with embryonal-cell carcinoma of the testis, adenocarcinoma of the breast, undifferentiated carcinoma (primary site unknown), and reticulum-cell sarcoma.

A man aged 23 years had a right orchidectomy and bilateral iliac and preaortic lymph-node dissections in March, 1958, for embryonal-cell carcinoma (fig 1) This was followed by X-ray treatment to the retroperitoneal area during the spring of 1958 The patient was well until March, 1959, when chest pain, hæmoptysis, and exertional dyspnœa developed. A chest film revealed large bilateral pulmonary metastases (fig 2a) An Ascheim-Zondek test was negative at 500 µ per litre Urinary 17-ketosteroids were 9 0 mg per 24 hours and 11-hydroxysteroids 5 0 mg per 24 hours Combined treatment was begun on April 13 and completed on April 28 (2000r, esti-

mated tumour dose to the right hilar mass, plus 6170 mg of 5-fluorouracil) The irradiated metastatic lesion in the right hilum regressed (fig 2b), but the non-irradiated lesion in the left lung did not

Obviously, long-term studies with large numbers of cases will be necessary before a definitive evaluation of combined therapy versus irradiation alone can be attempted

We wish to thank Hoffmann-LaRoche, Inc , Nutley, N J , and the Cancer Chemotherapy National Service Centre for generously supplying 5-fluorouracil for this study This study was supported in part by grants-in-aid from the National Cancer Institute, United States Department of Health, Education and Welfare

ALCOHOLISM AND HEPATIC CIRRHOSIS

Sir,—Your report (Dec 12) of the meeting on alcoholism and cirrhosis of the liver, held in New York, mentions estimates that " one in sixteen of those who take alcohol becomes an alcoholic and about 8% of these will develop cirrhosis " Figures of 8% or 9% are usually quoted, however, as the proportion among " chronic alcoholics " who develop cirrhosis,[1 2] and by no means all alcoholics show the bodily and mental disorders which according to the definition of Haggard and Jellinek [1] and the W H O alcoholism subcommittee [3] denote " chronic alcoholism " For example, the proportion of " chronic alcoholics " among all alcoholics in the United States, according to Jellinek's latest estimates, is less than 20% [2] According to the W H O subcommittee, the term " alcoholics " includes not only those excessive drinkers who show " an interference with their bodily and mental health " but also those in whom drinking interferes with " their interpersonal relations and their smooth social and economic functioning ", and those " who show the prodromal signs of such developments " [4] Thus much less than 8% of all alcoholics can be expected to develop liver cirrhosis

As the figures of 8% or 9% refer to the incidence of alcoholic cirrhosis of the liver (among alcoholics with complications) relative to other complications of alcoholism, a decrease of other complications would automatically increase the relative incidence of liver cirrhosis among chronic alcoholics In North America, because of a considerable fall between 1943 and 1950, in the incidence of alcoholic polyneuropathy and of certain other complications, the relative incidence of liver cirrhosis among alcoholics with complications is now estimated by Jellinek as amounting to 14% or 16% Jellinek states, however, that these changes in the relative incidence of alcoholic complications have not occurred in Europe [2]

Much more common, of course, in alcoholics than liver cirrhosis is fatty infiltration of the liver [1] It seems that in this country the great majority of alcoholics entering mental hospitals which take a special interest in alcoholism hardly ever show clinical evidence of liver damage Such people often show abnormalities when investigated with a battery of liver-function tests [5] After a period of abstinence and a balanced vitamin-supplemented diet such laboratory abnormalities often prove reversible, thus corresponding to the improvement noted in your report

Liver cirrhosis is a very important complication of alcoholism, but it must not be forgotten that it occurs in a relatively small minority of alcoholics only, and in these at a relatively late stage of their alcoholic career In view of the deterioration of judgment and performance with even small quantities of alcohol,[6] it is not surprising that a great many alcoholics show evidence of behaviour disturbance long before they enter their " chronic phase " and possibly develop liver cirrhosis [7] The W H O expert committee on alcohol and alcoholism has pointed out that " while the physical and mental sequelæ of alcoholism have always been recognised as medical disorders, there has been much less readiness to regard as matter of medical concern the behaviour which results in these complications " [8] At present many alcoholics are not recognised as such till they have arrived at their late " chronic " stages Medical education on alcoholism, therefore, should not be exclusively or even predominantly concerned with the teaching of late complications but should lay due emphasis on the much more common and earlier disorders of conduct The teaching of medical students will then further contribute to the aim so rightly stressed in your report that " every effort should be made both to secure early diagnosis and to ensure continued abstinence "

St Bernard's Hospital, Southall, Middlesex

THE COST OF DRUG TREATMENT

Sir,—It is to be hoped that the departments of the Ministry of Health concerned with prescribing and its cost to the N H S will ponder well the revealing article by Dr Miller and Dr Smith (Jan 2) They rightly draw attention to the paradoxical economics of general-practitioner prescribing with especial relation to long-term saving of inpatient costs and national productivity by the use of some of the more expensive drugs in general practice

Over the head of every N H S practitioner hangs the spectre of a prescribing investigation with the possible (but very uncommon) consequence of deduction from his quarterly cheque of the cost of certain drugs considered necessary by him for his patients but not, apparently, by the powers that be These inquiries follow periods of full pricing of all prescriptions by the executive councils at intervals in each year In any case, local pharmacists will know in advance when " pricing " will be in operation and can warn doctors beforehand

As I have pointed out previously,[9] little or no attempt is made by drug manufacturers to inform doctors of the total cost to the N H S of their products The basic cost represents an artificial and in some cases minute proportion of the total cost of a prescription, as Dr Miller and Dr Smith have noted, and has a much more attractive appearance on advertising literature

Most of us suffer from the rapacity of patients, and all of us realise that refusal to prescribe a substance demanded by a patient against our better judgment *may* possibly lead to his transfer to another doctor who will prescribe it regularly with a clear conscience, with resulting *loss* of capitation fees to ourselves I wonder how many practices have been built up by high prescribing relative *to* neighbouring doctors at the expense of the national drug bill Complaisant negligence by doctors is perhaps a sub-conscious defence mechanism to safeguard our incomes! To achieve a balance in this respect is one of the most disturbing aspects of practice *to some of us* who work in areas where standards of living are increasing

Obituary

WILLIAM ERRINGTON HUME

Kt., C M.G , M A., M D Cantab , F R.C.P

Sir William Hume's early election to the staff of the Royal Victoria Infirmary gave him an unusually effective working span, but its length was appropriate to the work which he accomplished The Newcastle medical school valued his contribution as a pioneer of scientific medicine, an outstanding teacher, and an upright man He died on Jan 1 at the age of 80

His father, George Haliburton Hume, practised as a surgeon in Newcastle upon Tyne and took a large part in the building of the Royal Victoria Infirmary Hume himself was educated at Repton School and Pembroke College, Cambridge At the London Hospital he was clerk to Sir Bertrand Dawson, and after qualifying in 1904 he returned to Newcastle to hold a succession of resident appointments He was senior house-physician at the Royal Victoria Infirmary when it moved into its new buildings in 1906 Two years later he was elected to the staff and was also appointed demonstrator in pathology at Durham University From the first he was a brilliant teacher and his ward rounds and museum classes were always packed

When the war began in 1914 Hume, by virtue of his hospital appointment, became a lieut.-colonel in the 1st Northern General Hospital, but he was anxious to serve abroad and joined a casualty-clearing station though this meant a loss of rank. Soon afterward he was posted to Boulogne, where he joined his old chief Dawson in the organisation of centres for cases of D A H They also began an investigation into spirochætal jaundice, which S P. Bedson was invited to join He writes

"Hume and Dawson were interested in the cases of Weil's disease which were occurring in our troops in the wet trenches of Flanders, and Hume, knowing that I had been unable to obtain suitable war work, suggested to Dawson that it might be possible to have me transferred to them and made responsible for the laboratory side of their investigations This was arranged and I joined them to spend three most pleasant and valuable years working with them. Hume and I were billeted together in Wimereux near to the house in which I had installed my laboratory and next door to Lord Dawson and to a refugee French family from Lille Friendship with our French neighbours prospered and much of our leisure was spent enjoying the delightful hospitality of Madame Tisseyre and her family, Hume later married the elder daughter Not only did I find Hume a most valuable colleague, but he proved also to be a delightful companion. He was entirely unselfish, had a real sense of humour, was not unappreciative of the good things of life and was withal of a complete integrity The time spent in his company was the basis of a friendship which I shall always cherish."

Before the end of the war Hume was appointed consulting physician to the 1st Army, and for this work and his research on poison gas he was mentioned in despatches and received the C.M G After his return to civilian practice his papers on war nephritis and encephalitis lethargica were useful continuations of his work during these war years But his chief interest lay of course in cardiology Early in his days at Newcastle he studied intensively the heart rhythm in diphtheria As early as 1913 he had described what is now called auricular flutter, and as the subject of his Bradshaw lectures in 1917 to the Royal College of Physicians of London he chose paroxysmal tachycardia

He was elected F.R.C.P that year, and later he served the college as censor and as senior censor in 1941 In 1943 he gave a war-time Harveian oration with the appropriate title of "the physician in war in Harvey's time and after" In 1943 he had been appointed to the chair of medicine at Newcastle, but in 1940 on his retirement from his hospital appointment he resigned.

For some years he remained on the staff of the Newcastle General Hospital, and he was largely responsible for setting up the regional cardiovascular centre He gave much other counsel to the organisation of the services of the region in the early days of the National Health Service. He was knighted in 1952, the year when increasing ill health finally forced him to retire from practice

H G M recalls the advice he received when he became Dr Hume's house-physician in 1938 "Have every patient electrocardiographed, and always carry twenty 'Gold Flake' in your pocket"

"Hume (he continues) was a superb clinician, and the contrast between his astute empiricism and the more speculative approach of his assistant physician, James Spence, was a rewarding and sometimes diverting experience

"Hume held the chair of medicine largely by virtue of his clinical seniority Such a procedure would be unthinkable today, but in retrospect it furnished here and elsewhere a cadre of clinical professors many of whom yield nothing in eminence or achievement to their successors appointed on other grounds Of such was William Hume, a man of extraordinary mental acuteness, with no time whatever for cant or pretence, able to diagnose a humbug with the same instantaneous flair as he did auricular flutter His systematic lectures were unforgettable. As he entered the theatre he peppered members of the audience with searching questions based on the subject-matter of the previous meeting These lectures represented the essence of a vast personal experience, sifted by unflagging and meticulous observation. He never used a note or quoted an authority, but he always had an appropriate clinical anecdote at his fingertips, drawn from his war-time service in France, his experience as an outstanding witness in the courts, or his daily work as a busy and successful consultant physician in the colliery villages and great houses of Northumberland and Durham.

"One of a generation of great general physicians, many of whom were his close friends, Hume nevertheless encouraged genuine specialisation, particularly in his own interest of cardiology He maintained however an amused contempt for some of the more recent synthetic specialties, and for what he regarded as the essential triviality of much that currently passes for research.

"He lived and breathed medicine. His great delight was fishing, but even when he went up for a few days on the Border, a couple of beds were always kept empty for the cases, whether of heart-block, cerebral tumour, or obscure pyrexia, that were sure to be 'rung in' from Wooler or further north He retained this vivid interest in medicine until the end. Only a few weeks ago he summoned me to his home by a peremptory telephone-call to discuss and criticise a paper in preparation, about which he had heard in the course of the medical gossip with which he always loved to surround himself

"Truth to tell—and although he was never anything but kind—I think we were all just a little frightened of him. His juniors' only consolation was that Knowledge and Wisdom so palpably superior, though so lightly worn, seemed to be not without a slightly intimidating effect on many of his near-contemporaries"

Lord Moran writes

"I think of William Hume with Dawson and Wilmot Herringham as central figures of another time. Consulting physician to the British Forces in France in the First War, he was Dawson's right-hand man at Boulogne, and Herringham, who was inclined to be impatient with mediocrity, thought well of him After the war, Hume was one of the three founders of the Cardiac Club, where he was well liked as a keen, cheerful, and kindly man And John Parkinson has said that when they met he felt invigorated It is now a quarter of a century since he was a councillor at the College, having already given the Bradshaw lecture, soon he became a censor and a little later gave the Harveian oration I read what he wrote, for it was salted by horse-sense and always to the point Besides, he had the literary art

"About William Hume there was an air of distinction Moreover he was a master of his craft I think of him as among the two or three physicians in the Provinces whom I most wished visitors to England to meet He was a brave soul, though he had to contend with years of pain and crippling illness, it never seemed to get him down Lately he was so much in pain, so frail, and so weak that I used to telephone when I was in Newcastle to find whether he felt equal to a visitor But he was always ready to talk on anything save his own illness, and he never lost his healthy outlook I can only guess what he owed to the wisdom and understanding of his wife

"William Hume was a considerable figure in the North of England and I count him in the direct line of descent from those English physicians who, proficient in their art, were also men of affairs, the kind of men who had influence beyond their own calling"

Sir William Hume is survived by his wife, three daughters, and two sons One of his sons is in practice in Sunderland, and his eldest daughter is married to Sir John Charles

JOHN ERNEST ALFRED UNDERWOOD

C B E, M B, B SC Lond, D P H

Dr J E A Underwood, a former principal medical officer of the Ministry of Education, died suddenly on Dec 31, at the age of 73

The son of Ernest Underwood, of Blackheath, he was educated at Blackheath School, University College, London, where he was president of the Union, and University College Hospital He graduated B SC in 1910 and qualified in 1915, when he joined the R A M C., serving in France and India On his return to civilian life he took the M B and the D P H, and in 1921 he became medical officer of health and school medical officer for Willesden He joined the staff of the Board of Education in 1925 and succeeded Dr J A Glover as principal medical officer in 1941 He was appointed C B E in 1948 and retired in 1951

Underwood was particularly interested in the problems of children who were blind or deaf, and he represented the Government at the international conference on the welfare of the blind held in New York, in 1931 He was secretary of the Committee on Partially Sighted Children that reported in 1934, and was vice-chairman of the one set up in the same year to inquire into problems relating to children with defective hearing In his later years at the Ministry of Education he became increasingly concerned with emotionally disturbed children, and when the Committee on Maladjusted Children was appointed in 1950 he was made chairman The work of this committee occupied much of his time during the first years of his retirement The committee's main recommendations were accepted by the Government and were the subject of recent circulars from the Ministries of Education and Health on the development of child-guidance services From early in his retirement he was a member of the governing bodies of Moor House School for Children with Speech Defect, Oxted, and the Heritage Craft Schools and Hospitals, Chailey, and also of the Mid-Sussex hospital management committee

A colleague writes

"Underwood read widely and he had a good collection of books His presidential address to the Medical Officers of Schools Association was a scholarly review of the allusions to medicine in the works of Shakespeare He enjoyed foreign travel He was somewhat reserved in manner but to those who knew him well he was an excellent companion, with a nice, but never malicious, wit and a great depth of common sense. He was never known to lose his temper and was tolerant to a degree that sometimes became embarrassing

"On the day of his death, as was his custom, he went for an afternoon walk with his collie dog across the fields near his home in Sussex When darkness came down and he did not return a search party went out, but his body was not found until next morning he lay in the field where he collapsed, guarded by his dog who, at first, fiercely resisted the searchers"

Dr Underwood is survived by his widow, Catherine German, whom he married in 1923

JOHN RITCHIE

M B Edin, F R C P E, D P H

Dr John Ritchie, formerly medical officer of health for Dumfriesshire, died in Edinburgh on Dec 24

Born and educated at Brechin, Angus, he qualified from Edinburgh University in 1906 and took the D P H the following year After holding appointments in the City Hospital, Edinburgh, as resident, senior assistant, and bacteriologist, he was appointed depute medical officer of health and bacteriologist to the County of Dumfries where he spent the rest of his career He became M O H in 1924 and he retired in 1917

In 1935 he was appointed to the General Medical Council as Crown nominee for Scotland and he held this appointment for ten years, serving also as chairman of the Council's public-health committee from 1939 to 1945 He was a member of the National Insurance Advisory Committee from 1947 to 1952.

He retired to Edinburgh in 1947 and was soon taking an active part in the medical affairs of the city, especially in the Royal College of Physicians He became superintendent of the College laboratory in 1948 and was the last of a long line of distinguished superintendents, for the activities of the laboratory ceased in 1950 Later he was honorary librarian of the College, a position from which he only recently resigned He had a deep interest in medical history and made many contributions to the subject, including a history of the laboratory of the College He was a founder member of the Scottish Society of the History of Medicine, serving as its president from 1951 to 1954

A colleague writes

"No more will we see the familiar erect figure of Dr Ritchie in the precincts of the College of Physicians or of the many libraries which were the great centres of his interest after he retired to Edinburgh He was a prodigious worker resembling in many respects Osler of whom he was a keen admirer A copious note-taker, all items which interested him were entered into his commonplace books and all carefully indexed Thus it was that his contributions to medical and medico-historical literature were fully documented and appropriately illustrated by well-chosen examples In his earlier years he had thought of becoming a naval architect, and he had a keen appreciation of art His letters and reports were often enlivened by the artistic touch, and by the fitting phrase for he was a man of wide reading and culture He had, too, a great gift for short story writing, mainly in lighter vein, and contributed to various magazines For all his accomplishments and ability, he was a quiet self-effacing man who loved the intimacy of the family circle and deliberately shunned the public eye"

CEDRIC SYDNEY LANE-ROBERTS

CVO, MS Lond, FRCS, FRCOG

Mr Cedric Lane-Roberts, consulting obstetrical surgeon to Queen Charlotte's Hospital and consulting gynæcological surgeon to the Royal Northern Hospital, London, died on Dec 25 at the age of 71

He was the third son of the late Lieut-Colonel A S Roberts and he was educated at Cheltenham College and Guy's Hospital where he was distinguished as a medallist and as a rugby player He qualified in 1913 and was mentioned in despatches for his service in the R A M C during the 1914–18 war After demobilisation he held for a time the appointment of tutor in obstetrics and resident medical officer at Leeds Maternity Hospital In 1920 he took the M S and the F R C S, and soon afterwards he returned to London on his appointment as chief assistant in the women's department and obstetric tutor at St Bartholomew's Hospital Later he was appointed to the staffs of Queen Charlotte's Hospital and the Royal Northern Hospital and he also built up a large consultant practice He contributed to the *Royal Northern Operative Surgery* and the *Queen Charlotte's Practice of Obstetrics* He was joint author of *Sterility and Impaired Fertility*

He was a foundation member of the Royal College of Obstetricians and Gynæcologists and he was elected to the fellowship in 1933 He was appointed C V O in 1942

K W writes

"*Who's Who* tells you the facts about Lane-Roberts, his hospital appointments and that he played in the English Rugby Football team four times and in the Guy's Hospital team for six years, but the real Cedric Lane-Roberts, the big-hearted colleague with whom it was impossible to quarrel, is not revealed He was undoubtedly a big, heavyweight bustling international forward, but he was big in many other fields than rugby football Never have I worked with a colleague so loyal and dependable as he, and I saw a great deal of him at the Royal Northern Hospital We were both interested in the subject of human fertility and having secured some funds from what is now the Beecham Trust we were able to establish there one of London's earliest parenthood clinics But again I am giving a lopsided account of a man who had many interests outside his professional work One was always unearthing unexpected hobbies in him Greek architecture, ancient Chinese bronzes and lacquer work, Tibetan pictures of the Buddha, and, more prized than all these—his garden at the Mill House, Tewin"

Mr Lane-Roberts married Nell Miles-Sharp, daughter of the late D W Bain, and she died in 1954

Notes and News

A COLLEGE BILL

In the life of an institution, a family, or an individual, a flitting is an opportunity for repair, replacement, and renovation In preparation for its move from Pall Mall East to Regent's Park, the Royal College of Physicians is presenting a Private Bill to Parliament to modify and clarify some of its ancient rights

The first, though not perhaps the most important clause of the Bill, proposes that the college shall be called and known as "The Royal College of Physicians of London" This title is already familiar by usage and repute But in the original royal charter, granted in 1518 by King Henry VIII, the college is described as "The President and College or Commonalty of the Faculty of Physic in London", and it may be that this pleasant, if cumbersome, name is the only one it has actually been authorised to use Though the familiar form stands in the Medical Acts since 1958 the archaic form has been retained in most of the college's legal documents, including those drawn up when it moved to Pall Mall East from the City

The second clause of the new Bill deals with another difficulty which the college first met at the time of this earlier removal Under the original charter it was only empowered to hold its meetings in the City of London, and when it moved to Westminster powers had to be obtained to allow it to act there Under the new Bill, its territorial choice would be extended to the whole of England

A third clause removes a limitation imposed by the Act of 1814, which only allows the college to hold lands of an annual value not exceeding £1000 a year, a ceiling which changing values has unfortunately made unsuitable

TWO-YEAR MEDICAL SCHOOLS

In the past twelve years the John and Mary R Markle Foundation has taken a special interest in the support of young doctors planning careers in teaching and research at medical schools in the United States and Canada In the latest annual report Mr John M Russell, executive director, cites the Bayne-Jones report to the Department of Health, Education, and Welfare, which suggests that in the next ten years at least 1900 additional doctors will have to be trained One of the ways proposed for training them is to increase the number of "two-year" medical schools, which cover the first two years of the medical course and send their students elsewhere for clinical work

In several of the large American cities the medical schools have clinical facilities not fully utilised and could handle more students, while "some colleges", Mr Russell says, "have excellent departments in the life sciences which could be expanded without great expense into a two-year medical course" Professors at these colleges may be reluctant for several good reasons "a medical school, next to the football team, can cause the most headaches in any university", and they fear that the additional tasks may mean more teaching and less research While agreeing that basic research must be protected at all costs, Mr Russell feels that the attitude toward teaching is another matter

> "The lack of interest in teaching undergraduates in American institutions with graduate schools is a curious phenomenon and seems to stem from the methods used to climb the academic ladder To get a promotion or a new job, to get tenure and more pay, it is important to publish, and to publish requires research There is, in fact, little incentive to teach However, at the graduate level teaching is favored Graduate students are involved with research, and the research usually is in the particular area of interest of the professor" Hence "the reluctant professors should not be taken too seriously Teaching does have its satisfactions and there are ways in which the teacher can be recognized with pay, rank and tenure, while at the same time protecting his time for research"

The Foundation has distributed nearly $5^1/_2$ million dollars since it was established in 1927 Its address is 511, Fifth Avenue, New York City, 17

Hellingly Hospital, Sussex

Last July the first patients were taken into the new 60-bed unit for the investigation and treatment of early psychiatric illness which has been built for Hellingly Hospital (near Hailsham) two miles from the main building It is called Amberstone Hospital, and patients are admitted on the recommendation of any member of the Hellingly consultant psychiatric staff Instead of having an official opening, Dr David Rice (the medical superintendent) and his colleagues have held open days for the doctors of the neighbourhood, who were invited to meet the senior staff, discuss any subject in which they were interested, and see demonstrations of electroconvulsion therapy

The unit will take 35 female and 25 male patients Accommodation is in single rooms or in curtained cubicles in the 4-bed and 8-bed dormitories The staff is mixed one shift has a sister in charge (with a male staff nurse as second in charge) while the other shift has a charge male nurse with a female staff nurse as his first assistant

University of Liverpool

On Wednesday, Jan 20, at 8 P M , at the Medical School, Ashton Street, Liverpool, Dr W H Taylor will give the first of eight weekly lectures on biochemical aspects of disease Tickets (£2 2*s*) may be had from the director of extramural studies, 9, Abercromby Square, Liverpool, 7

University of London

Dr D R Newth, lecturer at University College, has been appointed to the chair of biology as applied to medicine at Middlesex Hospital Medical School

The degree of M S has been conferred on Gerald Keen

University of Glasgow

Dr W M Gibson has been appointed to the chair of dental prosthetics

Royal Statistical Society

Frances Wood Prize (£50)—This prize is offered for an investigation, on statistical lines, of any problem which bears " directly or indirectly upon economic or social conditions " Competitors must be under 35 Further particulars may be had from the honorary secretaries of the society, 21, Bentinck Street, London, W 1 The closing date for entries is Dec 31

James Yearsley Lecture

Mr Ian Thorburn will deliver this lecture on Friday, March 4, at 5 P M , at 1, Wimpole Street, London, W 1 His subject will be tympanoplastic surgery

Anglo-French Exchange Bursaries

Short-term grants for work in France are offered again this year to British doctors and medical research workers by the Institut National d'Hygiene, Paris Details and application forms can be had from Dr G E W Wolstenholme, Ciba Foundation, 41, Portland Place, London, W 1 The closing date is Jan 31

Appeal to the Privy Council

Dr Kenneth Fox has lodged an appeal with the Judicial Committee of the Privy Council against the decision of the Disciplinary Committee of the General Medical Council to erase his name from the register

Dr D A Buxton Hopkin, consultant anæsthetist at Charing Cross Hospital, London, has been appointed the first McDermott visiting professor of anesthesiology in the University of Texas The appointment is for one year and Dr Buxton Hopkin expects to take up the post early in April

On Wednesday, Jan 13, at 5 30 P M , at the Fountain Hospital, Tooting Grove, London, S W 17, Prof L S Penrose and Dr P E Polani will speak on chromosomal abnormalities in the mentally retarded

At the request of the Government of Pakistan the British Government under the auspices of the Colombo Plan, have asked Prof Charles Wells and Prof H P Gilding, as members of a Pakistan Commission to report on the health services organisation in Pakistan They leave in January for a tour of three months

G.P.I. IN AN OBSERVATION WARD

ROBIN STEEL
M.B. Lond., D.P.M.
LATELY SENIOR HOUSE-OFFICER IN PSYCHOLOGICAL MEDICINE,
UNIVERSITY COLLEGE HOSPITAL, LONDON, W.C.1

SYPHILIS is not in fact a " dying disease " (King 1958), but, despite warnings (Harris 1958, Mayer-Gross 1958), parenchymatous neurosyphilis is generally thought to be very rare.

During the eighteen months from April, 1957, to September, 1958, at St Pancras observation ward, 18 cases of general paralysis of the insane (G.P.I.) were admitted. Of these 12 were hitherto untreated. In addition 1 case of juvenile G.P.I. and 2 patients with dementing illnesses and positive Kahns reactions, but negative blood Wassermann reactions (W.R.) and cerebrospinal-fluid (C.S.F.) findings, were admitted. These last 2 patients had recently had intensive antibiotic treatment for respiratory infections, and 1 died of syphilitic aortitis proven at necropsy.

Patients are admitted to the 70-bedded observation ward by the London County Council duly authorised officers and police, usually from central London and north of the Thames, on an order lasting seventeen days. Blood W.R.s and Kahn reactions are taken routinely on admission, and all patients with neurological conditions are examined by the consultant neurologist.

To show the various ways in which cases are still presenting, and to emphasise that clinical examination without serological examination is insufficient to exclude syphilis, brief case-histories of the 12 untreated and 2 recently treated cases are recorded.

Case-reports

Case 1.—A 53-year-old lorry-driver was admitted from a police-station. He was disorientated and confused, and believed he could be saved by Spilsbury. Although all reflexes were increased, his plantar responses were flexor. He had a cerebellar tremor of his left hand. There was no proprioceptic loss or pupillary signs. After treatment with chlorpromazine and penicillin he was transferred to a mental hospital, but he was so upset on hearing a membership tutorial class suggest that he may have " G.I.P. ", that he returned to the observation ward. Although not psychotic, he was irresponsible. He had a valid driving licence, and would not consider alternative plans. He remained for a month on a voluntary basis, during which he was well except that he imagined himself to be one of the nursing staff. When he discharged himself he was adamant that he had no general practitioner but used the casualty department of a teaching hospital for this purpose. He had recently had his teeth extracted there for arthritis and malaise.

Case 2.—A senior clerk, aged 51, with a good war record in the R.A.M.C., had been attending his general practitioner for a year with lassitude. Three weeks before admission to hospital he attended a psychiatrist at a teaching hospital, but he failed to respond to tablets and was admitted there for two days. Because of his retardation and delusions of guilt, he was transferred to the observation ward. There were no abnormal physical signs. Mentally he was slow and dejected, believing himself to be doomed. His condition showed no improvement after a full course of penicillin, but a month later, after electroconvulsive therapy (E.C.T.), it was greatly improved. His I.Q. was then 104, and there was no evidence of dementia. He was discharged home and follow-up at the other hospital was arranged.

Case 3.—A 37-year-old Sierra Leone ex-seaman was transferred from a neurosurgical unit where he had spent a week for investigation after an epileptic fit; he had then become overactive. His hæmoglobin was 85%, white blood-cell count 7200 per c.mm., and erythrocyte-sedimentation rate (E.S.R.) 65 mm. in the first hour (Westergren). On admission to the observation ward the only abnormal physical signs were tibial scars. Mentally he was restless, he prowled around and was overactive. After being given penicillin he was found a new job and lodgings, and was discharged greatly improved.

Case 4.—A clerk, aged 47, who had graduated from one of the older universities had been having treatment for migraine at a teaching hospital. He had been remanded for a medical report by a magistrates' court. The prison medical officer regarded him as certifiably insane, and he was admitted to the observation ward from court. Physical examination showed a fine tremor only. Mentally he was euphoric, demented, and unconcerned; his I.Q. was 94. He went to a mental hospital as a voluntary patient.

Case 5.—A 72-year-old Pole had been under the care of geriatricians for seven months. He had had several little strokes in the past six years, and his son and family, who cared for him, had noted that though once he could speak six languages now he could use only his native tongue. He was grossly demented, and he had small irregular pupils and a right-sided mild hemiparesis. He went to a mental hospital on form " A " after treatment.

Case 6.—A man aged 47, a drain flusher, had just been in prison where the doctor regarded him as a psychopath with a social problem, but not as certifiably insane.

He was admitted to the general wards of University College Hospital because the pædiatrician at another hospital, where he had taken his stepson, thought he looked ill. He was febrile (103°F), with a resolving pneumonia, but he also had irregular pupils, ptosis, and an upper-motor-neurone lesion of the left arm. Mentally he was euphoric and demented. Next day, when his behaviour deteriorated and his temperature fell, he was transferred to the observation ward. From there he went to a mental hospital as a voluntary patient.

Case 7.—A single milliner, aged 42 (the only untreated female patient) of Continental extraction, had not worked for six months. She had only just been discharged from a teaching hospital after operative treatment for varicose veins.

She showed fixed irregular pupils, ankle-clonus, and a left extensor plantar response. She had grandiose delusions and was hypomanic and disorientated. She was certified.

Case 8.—A 44-year-old housewife, whose youngest child was educationally subnormal, had for six months been attending a psychiatric clinic with the label of " hypomanic reaction in a woman of low intelligence ". She had been a surgical inpatient for assessment of her incontinence.

The only abnormal physical signs were one tibial scar and a right extensor plantar response. Mentally she was overactive and elated, with occasional paranoid fears.

In view of a negative blood W.R. and adhesions in a chest radiograph, her C.S.F. was cultured but there was no growth. There was no other evidence of tuberculosis. Skull radiographs, an electroencephalograph (E.E.G.), blood-count, and E.S.R. were all compatible with G.P.I. She was certified and transferred to a mental hospital.

Case 9.—A Post Office engineer, aged 27, was admitted from a police-station in an excited condition, his personality having changed over the previous ten days. His left pupil was oval and sluggish, and he had diminished reflexes and proprioceptive sensation in the legs, but bilateral extensor plantar responses.

He was manic, he thought he was Christ and must clean up London with a hydrogen bomb. After treatment with chlorpromazine he became quieter and agreed to go to a mental hospital as a voluntary patient

Case 10 —A 38-year-old greyhound attendant had been forgetful for a month, and grandiose for two days He had had an episode, eight years ago, of confusion with twisting of his left arm and mouth, which improved after six weeks' conservative treatment at home He had served on the Continent with the Army Catering Corps during the war

He had irregular, small, but reactive pupils, and his plantar responses were doubtfully extensor Mentally he was glib, euphoric, and disorientated, he claimed to have sold 20,000 pigs at Smithfield He frequently attributed his admission to the observation ward to a head injury caused by falling off his personal elephant in the Australian jungle An E E G showed diffuse abnormalities He was transferred to a mental hospital as a voluntary patient

Case 11 —A 44-year-old Hungarian refugee, whose mother, two siblings, first wife, and two children had been killed in concentration camps, had also been imprisoned himself for three years Shortly after coming to England, eighteen months previously, he had learnt that his second wife had leukæmia, and this, with his inability to find employment or to learn English, produced a severe melancholia He was treated with a course of E C T , vitamins, and euphoriant drugs in the psychiatric outpatient department of a postgraduate institute for eight months He made a good recovery but was forgetful A week before admission to the observation ward his wife died, and he became noisy, agitated, and suicidal

Physical examination was difficult at first because he was so suspicious, but his pupils were seen to be large and unreactive to light No other abnormal signs were found later He was restless, agitated, and preoccupied with mourning ritual He spoke no English, but his friends said his paranoid ideas had ceased

After treatment with penicillin he was seen by a Hungarian-speaking psychiatrist who said the clinical picture was only one of dementia He returned to the care of his relatives and friends

Case 12 —An electrical engineer, aged 54, had come to England from Belgium when he was 13 He had been a good workman but four years previously had begun to steal, and he had been unemployed for the past two years At first he lived on his savings, but he spent these rapidly He then lived for a year on the charity of his neighbours, becoming more eccentric and grandiose, and going to the police-station to say that he had won two Nobel prizes

He had fixed small pupils, slurred speech, tremor of his tongue, very brisk reflexes, clonus, and extensor plantar responses He was euphoric, with delusions of grandeur

He was certified and transferred to a mental hospital

The table shows the findings in the C S F and blood in these 12 cases before treatment All were treated with penicillin by injection as soon as the diagnosis was made, and where possible a course of 28 million units was given No side-effects arose No other antisyphilitic drugs were used (Kofman 1956)

FINDINGS IN C S F AND BLOOD IN 12 UNTREATED CASES OF G P I

Case no	C S F				Blood	
	White cells (per c mm)	Protein (mg per 100 ml)	Lange curve	W R	W R.	Kahn
1	13	150	5 5 5 5 5 5 5 5 4 4	+	+	+
2	23	70	5 5 5 3 3 1 0 0 0 0	+	+	+
3	30	50	5 5 5 4 3 2 0 0 0 0	+	+	+
4	45	100	5 5 5 3 1 0 0 0 0 0	+	+	+
5	6	130	5 5 5 5 4 2 1 0 0 0	+	+	+
6	32	90	5 5 5 5 3 1 0 0 0 0	+	+	+
7	32	110	5 5 5 5 5 5 4 4 3 2	+	+	+
8	70	70	3 4 5 4 2 1 1 1 0 0	+	−	+
9	13	50	5 5 4 3 1 0 0 0 0 0	+	+	+
10	5	40	5 5 5 4 2 1 0 0 0 0	+	+	+
11	5	65	5 5 5 4 3 2 1 0 0 0	+	+	+
12	15	70	5 5 5 5 3 2 1 0 0 0	−	−	+

The following 2 cases had been treated before admission to the observation ward

Case 13 —A 46-year-old Cypriot had been in England for three years After a fall from a bus, nine months previously, his condition began to deteriorate He complained of difficulty in walking, but was sent away from a postgraduate teaching hospital as a hysteric Three months earlier he had been in another observation ward after threatening suicide by trying to climb on the Underground track. His pupils reacted sluggishly, he was sullen, negativistic, and deluded

After the diagnosis of G P I was confirmed, he was transferred to a postgraduate teaching institute There, despite penicillin, tranquillisers, E C T and barbiturates intravenously, and although some of the staff spoke his own language, he became worse and refused food As he was unfit to be a non statutory patient, he was sent home and seen there by the duly authorised officer Since the diagnosis was in no doubt, he was transferred to a mental hospital under certificate without further investigation

Case 14 —An Irishman, aged 59, had been a commissionaire and was now a waiter In 1946 he attended the venereal-disease department of a teaching hospital, where his W R was found to be positive and he was given one injection of penicillin. He failed to return for further treatment, although he knew that, as well as his gonorrhœa which was cured, he had a " touch of the pox " He entered another teaching hospital in 1948 with lymphadenopathy, and a biopsy diagnosis of reticular sarcoma was made According to their postal follow-up inquiry, he was well in 1958

Towards the end of 1957, because of failing vision he went into another hospital A diagnosis of neurosyphilis was made, and he was transferred to a postgraduate institute for treatment The C S F contained 16 white cells per c mm protein 125 mg per 100 ml Lange curve 5 5 5 5 5 3 3 3 3 3 His neurological signs were unchanged, but he began to have paranoid ideas He was seen after discharge by the psychiatrist, and accepted an offer of treatment as a voluntary patient at a mental hospital While this was being arranged he travelled to Dublin to implore the police to cease accusing him Having failed to stop the hallucinations, he returned to London and was admitted to the observation ward

He had optic atrophy, ptosis, irregular pupils, absent ankle-jerks, and diminution of proprioception, and a left extensor plantar response He was haunted by horrible accusing hallucinations, and, apart from the accompanying depression, he showed slight dementia

As the original voluntary-patient vacancy was for the next day, he was then transferred to the mental hospital He discharged himself against advice, and he was readmitted to the observation ward eight days later in an unchanged state The blood W R was negative and the Kahn reaction positive The C S F contained 1 white cell per c mm , protein 50 mg per 100 ml Lange curve 5 5 5 5 4 3 1 0 0 0 He was returned to the mental hospital, under certificate, having started another course of penicillin

Discussion

Neurosyphilis is probably more common than is assumed Hughes (1959) described 10 recent untreated cases presenting to a neurosurgeon Only cases which fail to reach general or mental hospitals, or do not get effective treatment, will be seen in an observation ward Routine serological examination obviously still has a place on economic as well as humanitarian grounds Psychotic episodes may arise in treated cases with a resolving or normal C S F , even after adequate antisyphilitic therapy, and a more careful follow-up or a warning to the near relatives might reduce the interval before they receive psychiatric treatment

The National Health Service seems very well suited to the needs of the peripatetic ex-patient who has no relatives to remind him to attend a follow-up clinic, for if he changes his general practitioner his new doctor should receive his record card, including any letters from hospital Unfortunately, however, few of these patients bother to register with a doctor, and they will probably continue to be treated as temporary patients, or at casualty departments where their past is unknown

Summary

18 cases of general paralysis of the insane, were admitted to one observation ward within eighteen months

The case-histories of 12 untreated and 2 recently treated patients are recorded to show the variable clinical picture

Syphilis is by no means a dying disease, and routine serological examination is important

I should like to thank Dr E W Dunkley for his permission to publish and his criticism.

TREATMENT OF ADVANCED CARCINOMA OF THE BREAST BY BILATERAL OOPHORECTOMY AND PREDNISONE

DIANA M BRINKLEY
M B Lond , D M.R.T
ASSISTANT IN CLINICAL RESEARCH TO THE REGIUS PROFESSOR OF PHYSIC, UNIVERSITY OF CAMBRIDGE

ELIZABETH KINGSLEY PILLERS
M.D Cantab , D C H , D M R.T
SENIOR HOSPITAL MEDICAL OFFICER, ADDENBROOKE'S HOSPITAL, CAMBRIDGE

FOR many years the production of hormonal imbalance has been used in the treatment of advanced breast cancer In 1896 Beatson suggested therapeutic castration and Treves and Finkbeiner (1958) review the historical background At this hospital, owing to the short-lived remissions following bilateral adrenalectomy and oophorectomy and the difficulty of maintaining these patients in electrolyte balance, it was decided to try the effect of bilateral oophorectomy together with corticosteroid treatment Reports on similar methods have already been given by Nissen-Meyer (1957) and Lemon (1959), and the present report concerns the treatment of 82 patients with advanced carcinoma of the breast

Material and Methods

All the patients selected had advanced carcinoma of the breast, and at the time of surgical castration were grouped as stage-iv cases Most patients had been treated previously by radical surgery and radiotherapy Several patients had hormone treatment when their metastases were first noticed, and it was not until the remissions from this treatment were exhausted that bilateral oophorectomy was undertaken. A smaller group of patients seen for the first time when their disease was already very advanced were initially treated by oophorectomy and prednisone The ovaries were removed either at Addenbrooke's Hospital or at one of the smaller hospitals in the area served by the Addenbrooke s Radiotherapy Department Prednisone 10 mg b d. was started as soon after surgery as practicable—usually within 48–72 hours

The response to treatment was evaluated by careful clinical follow-up, subjective and objective improvement were noted, and tumour regression also measured wherever possible The quality of remission was considered to be no less if not more, important than the length of survival following operation

A response was considered *satisfactory* if there was evidence of objective and subjective improvement enabling the patient to lead a relatively normal life again Such a response was considered terminated when further palliative measures were necessary in order to prolong useful life

TABLE I—MENOPAUSAL STATUS IN RELATION TO RESPONSE

Menopausal status	No of patients		Satisfactory response	
	"Primary"	Advanced	"Primary"	Advanced
Premenopausal	9	43	6	17
Menopausal	1	8	0	2
Postmenopausal	0	10	0	4
No information	6	5	3	1
Totals	16	66	9	24

A response was classed as *unsatisfactory* if improvement was purely subjective and objective improvement could not be demonstrated.

To try and find out whether any features could be used for prognosis, the quality of the response was related to (*a*) the menopausal status of the patients, (*b*) the previous response to hormone therapy, (*c*) the presence or absence of ovarian metastases, (*d*) the length of history prior to oophorectomy

The question of ovarian cortical stromal hyperplasia was also considered, but the changes detected in the sections could not be assessed by a sufficiently quantitative method to give any information of value The presence of widespread liver metastases had been noted at operation in a few patients

Results

Of the 82 patients treated, 16 were in the group of "primary" oophorectomy, and, of these, 9 had a satisfactory response 66 were treated after other forms of therapy had failed, of these, 24 had a satisfactory response with definite objective improvement, and were able to lead an active and useful life following operation, the remaining 42 patients, although many survived for many months, were considered to have had unsatisfactory responses and continued to need frequent hospital care and further palliative treatment

Of the 16 patients treated in the first instance by castration 9 were considered to have a satisfactory response and 7 an unsatisfactory response. This group was a little more difficult to assess as they had not been under observation for any length of time before operation

Menopausal Status

The relation of the meopausal status to the type of response is apparently not important in either group of patients treated (table I) The menopausal status was, however, assessed at the time of primary treatment of the original lesion, and thereafter some considerable time elapsed before oophorectomy, and the situation was often further modified by the use of hormones

Previous Hormone Therapy

Hormone therapy had been prescribed before oophorectomy in 42 cases, but the response to this therapy was not always easy to assess, especially as the patients had been under the care of different doctors The response to hormone therapy was classified as positive (i e, the lesion classified as hormone-dependent), negative, or doubtful In the last category the changes in the patient's condition following hormone therapy were too indefinite to allow their lesions to be classified as "hormone-

TABLE II—HORMONE DEPENDENCE IN RELATION TO RESPONSE

Hormone dependence	Unsatisfactory response	Satisfactory response
Positive	10	10
Negative	5	1
Doubtful	11	5
Not tried	16	8
Totals	42	24

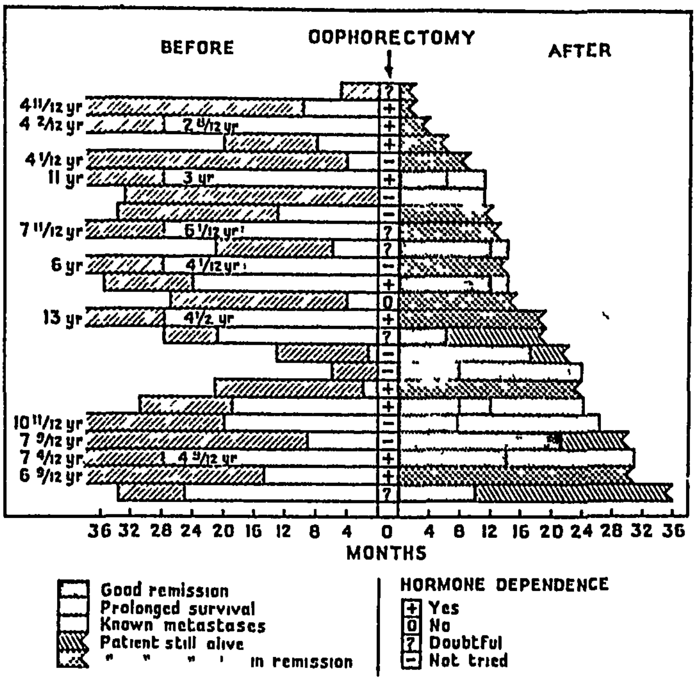

Fig 1—Satisfactory responses of patients with advanced carcinoma of breast to bilateral oophorectomy and prednisone

dependent" In order to avoid bias, the response to hormone therapy was always assessed before the response to oophorectomy was known In the satisfactory group 10 out of 16 patients were considered to have hormone-dependent lesions and in the unsatisfactory group 10 out of 26 (table II)

Ovarian Metastases

Metastases in the ovaries were found in 10 of the 44 specimens examined The degree of destruction of ovarian tissue varied enormously, and the response to operation seemed to be unrelated to these findings (table III)

Length of History Before Oophorectomy

In both the satisfactory and the unsatisfactory groups patients were known to have had the disease for many years The response to castration was apparently unrelated to the previous duration of the disease (figs 1 and 2)

TABLE III—OVARIAN METASTASES IN RELATION TO RESPONSE

Histological findings	No of specimens	Satisfactory response
Metastases present	10	4
No metastases	31	18
Not examined	38	11
Totals	82	33

Liver Metastases

Extensive metastases in the liver were noted at operation in 7 patients, and 2 of these subsequently had very satisfactory remissions

Other Metastases

The time from the first treatment to the first exacerbation of the disease was known in 60 patents Bone metastases were the first to develop in 28 patients, and 8 of these were subsequently classified as having had a good response to oophorectomy Of the 32 patients who first presented with soft-tissue spread 13 responded satisfactorily

Survival-time

The average survival-time for the advanced patients in the satisfactory group was 16 5 months, as against 6 months for the other advanced cases (fig 3). In the "primary" group the patients with a satisfactory response had an average survival of 16 months, and the others 3 months The results are summarised and the quality of remission together with the survival-time for each patient are shown in figs 1, 2, and 4

Case-records

The following 3 case-records illustrate the quality and the length of survival in a really satisfactory remission

Case A.—A childless married woman of 42 who noticed a lump in her breast in June, 1949 6 months later she reached hospital and had a radical mastectomy for a stage-II carcinoma of the left breast The histologist reported a mucoid papillary carcinoma of the breast A radical course of postoperative X-ray therapy was planned for the patient, but this treatment was never completed as she developed infective jaundice She remained in good health for five years, after which lung metastases developed in July, 1955 She was treated with testosterone propionate intramuscularly and obtained a good clinical remission for a year, although there was no improvement in the appearance of the metastases in chest X-ray films At the end of the year her condition worsened and radiography showed extension of the chest metastases

She had a bilateral oophorectomy in September, 1956, after which she had a temporary improvement of six weeks' duration Owing to a misunderstanding prednisone was not administered until 8 weeks after oophorectomy, when she was

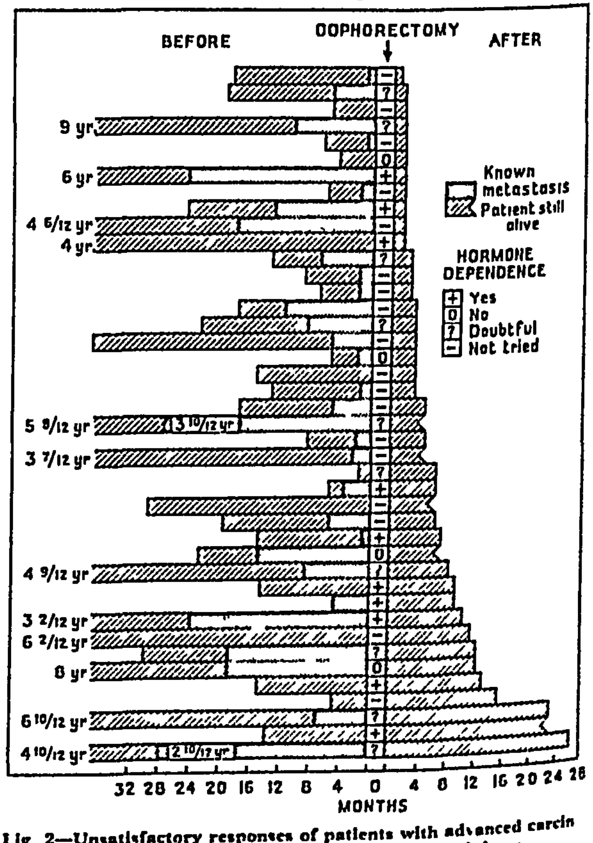

Fig 2—Unsatisfactory responses of patients with advanced carcinoma of breast to bilateral oophorectomy and prednisone

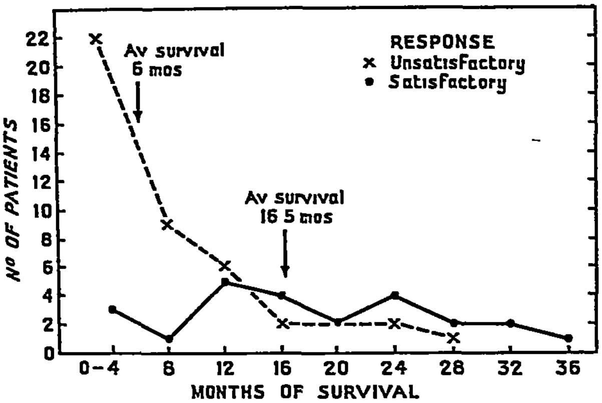

Fig 3—Distribution of satisfactory and unsatisfactory responses in relation to survival-time.

again distressed and was very dyspnœic at rest. Prednisone 20 mg. b.d. was then administered. Metastases in her chest steadily improved, and after 6 months the prednisone was reduced to 10 mg. b.d.

In the 33 months since oophorectomy her condition has continued to improve, and the last chest film shows no evidence of metastases. She is a little "moon-faced" but is able to lead a normal life. X-rays of the chest are shown before and after treatment in fig. 5.

Case B.—A married woman of 47 with 1 child had had a lump removed from her right breast 12 years previously by local excision. In May, 1955, she was referred with "sciatica", and radiography showed multiple metastases throughout her pelvis and spine with collapse of D11 vertebra. She also had a clinically malignant local recurrence of a breast tumour.

She was treated with palliative doses of X rays to her bones and injections of testosterone propionate, and had a fair remission with almost complete relief of pain. This remission lasted about 2 years, after which pains returned. She was admitted in October, 1957, with almost complete paraplegia due to further vertebral collapse.

Bilateral oophorectomy was performed and in October, 1957, prednisone 10 mg. b.d. was started 6 days post-operatively.

Since then her condition has steadily improved, and the only residual sign of paraplegia is a slight weakness in the left leg, which does not prevent her from leading a normal life and running her home. Her weight has increased a stone since her operation, but this does not worry her. Radiography shows little change since the oophorectomy, but there is some sclerosis of the metastases.

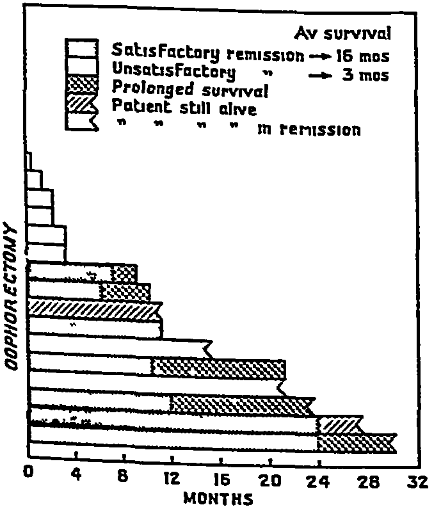

Fig 4—Response of patients with advanced carcinoma of breast to primary treatment with bilateral oophorectomy and prednisone.

Case C.—A married woman with 3 children first attended hospital in October 1954. For 2 years she had noticed a lump in the left breast, and a lump had been found in the right breast 6 months previously. There was a 4-month history of backache. Clinically there was a large ulcerated scirrhous carcinoma of the left breast with fixed axillary and supraclavicular glands. On the right the carcinoma and the axillary nodes were mobile. There were widespread skin metastases over the trunk and bone-marrow aspiration showed numerous malignant cells. As the patient refused bilateral adrenalectomy, intramuscular testosterone propionate was given, and the patient had a good remission until July, 1956. At this time the skin nodules were increasing in size and abdominal ascites was developing. There was slight improvement after the testosterone injections were stopped but by May, 1957, ascites was severe, and bilateral oophorectomy was performed on May 24. Prednisone 10 mg. b.d. was started 5 days after operation, and the patient improved and remained well until September, 1958, when ascites once more became a problem. Intraperitoneal gold in October, 1958, gave another short remission until February, 1959, when the patient started to deteriorate rapidly, she died in April, 1959, some $4^1/_2$ years after attending hospital with a very advanced neoplasm with bone-marrow involvement.

Discussion

Previous critical assessments of hormone treatment of advanced carcinoma of the breast have nearly all reported 30–40% of good results (see Treves and

Fig 5—Case C (*a*) 1 month before oophorectomy (*b*) 30 months after oophorectomy.

Finkbeiner 1958) It seems that 30–40% of patients are likely to have "hormone-dependent" tumours, but the type of hormone treatment which gives the most satisfactory results is not yet clear, and as yet there is no method of determining which patients are likely to have "hormone-dependent" tumours

The present series indicates that patients who have had a remission following androgen treatment are likely to get a further remission from oophorectomy and prednisone However, failure to respond to androgen does not necessarily indicate that oophorectomy will fail, and as yet we have no method of selecting patients who are likely to respond satisfactorily to oophorectomy

The advantages of bilateral oophorectomy followed by administration of prednisone are, firstly, the comparatively minor nature of the operation with an average stay in hospital of 10 days, and, secondly, the prednisone besides helping to suppress the tumour imparts a feeling of well-being In addition, administration of low doses of prednisone does not require much supervision Operation is necessary because X-ray castration does not completely stop ovarian function A patient in pain preoperatively who responds to operation will probably be completely relieved of pain as soon as she has recovered from the anæsthetic The only disadvantage of this treatment seems to be the increase in weight due to fluid retention, but this is an embarrassment to only a minority of the patients

We do not know how the prednisone acts Through the pituitary it may suppress adrenal function, or it may act directly on the tumour Experience has indicated that 20 mg daily is about the optimum dose, and we think it likely that its action is not simply that of a euphoriant

Summary

82 patients with advanced carcinoma of the breast were treated by bilateral oophorectomy and administration of prednisone

16 patients were treated by "primary" oophorectomy, and 9 of these had a satisfactory response their average survival-time was 16 months, compared with 3 months for the 7 patients in the unsatisfactory group

66 patients were treated when remissions by X-ray and/or hormone therapy were exhausted 24 of these had a satisfactory response with an average survival-time of 16 5 months, compared to 6 months for the 42 other patients Of 16 patients showing a satisfactory response, 10 were found to have hormone-dependent tumours, whereas of 26 showing an unsatisfactory response only 10 were considered to have hormone-dependent tumours

The menopausal status, the presence of ovarian metastases, and the length of history before oophorectomy or liver involvement appeared to be of no definite prognostic significance

Bilateral oophorectomy and administration of prednisone are useful in the treatment of patients with very advanced carcinoma of the breast

We would like to thank our many colleagues in this area who have directly and indirectly helped with this project, and Prof J S Mitchell for his helpful discussion of this paper

TREATMENT OF INGUINAL HERNIÆ

K E D SHUTTLEWORTH
M B Lond, F R.C.S
SENIOR SURGICAL REGISTRAR

W H DAVIES
M Chir Cantab, F R C S
RESIDENT ASSISTANT SURGEON

ST THOMAS'S HOSPITAL, LONDON, S E 1

St Thomas's Hospital has long been associated with the medical care of members of the Metropolitan Police Force As a result it has been possible to achieve a high follow-up rate after these patients leave hospital

The results of operations for inguinal hernia on members of the Metropolitan Police were reviewed by N R Barrett in 1934, and by A G McPherson in 1943, on behalf of Sir Max Page (1934, 1943)

In view of the new techniques introduced in recent years it was thought that a further review might be of value An attempt was made to examine all Metropolitan policemen, totalling 266, who had been operated upon for inguinal hernia between 1945 and 1954, the follow-up period being between 12 and 4 years

The great majority presented themselves for examination 23 who had retired from the Force and lived far away were seen by their own doctor, a few were unresponsive and had to be visited in their own homes All those included in this series were medically examined Postal questionnaires were not used

Findings

Of the 266 patients, 5 had died of intercurrent disease and 5 were untraced (2 in the U K, 1 in Canada, 1 in the U S A, and 1 in Australia)

The 256 who were successfully followed up had an average age at operation of 40 years (range 21–60)

Inguinal herniæ operated on numbered 335 (i e, 79 had bilateral herniæ) Recurrences totalled 48 (14 3%) The recurrence-rate according to type of hernia is shown in table I Tables II–IV show the recurrence-rates for indirect, direct, and recurrent herniæ related to the types of operations

No definite reason was found for the choice of repair operation It appeared to depend on the type of operation in favour at the time, and on the particular surgeon's beliefs, except that herniotomy and plication was reserved for very minor weakness of the posterior wall, and that the Bassini operation was not done on the bigger direct herniæ.

TABLE I—RECURRENCES IN 335 HERNIÆ

Type	No	Recurrences
Indirect	204	29 (*14 2%*)
Direct	94	17 (*18 3%*)
Recurrent *	37	3 (*8 1%*)

* First operation at St Thomas's Hospital in 28, elsewhere in 9, cases

TABLE II—RECURRENCES IN 204 INDIRECT HERNIÆ

Operation	No	Recurrences
Herniotomy	54	9 (*16 7%*)
Herniotomy + plication of transversalis fascia	13	2
Bassini	26	8 (*30 8%*)
Bassini + Tanner slide	10	2
Gallie	44	3 (*6 8%*)
Floss silk darn *	12	2
Bloodgood	3	0
Nylon darn	40	2 (*5%*)
Others	2	1
Total	204	29 (*14 2%*)

* Method used by one surgeon only

TABLE III—RECURRENCES IN 94 DIRECT HERNIÆ

Operation	No	Recurrences
Herniotomy+plication	3	0
Bassini	12	3
Bassini+slide	5	1
Gallie	28	6 *(21·4%)*
Floss-silk	6	2
Bloodgood	5	0
Nylon darn	32	4 *(12 5%)*
Others	3	1
Total	94	17 *(18 3%)*

TABLE IV—RECURRENCES IN 37 RECURRENT HERNIÆ

Operation	No	Recurrences
Herniotomy	2	0
Bassini	4	1
Bassini+slide	1	0
Gallie	5	1
Bloodgood	1	0
Nylon darn	18	0
Others	6	1
Total	37	3 *(8 1%)*

These results compare with

Barrett, 1934—206 cases treated predominantly by Bassini or Foster technique, with a recurrence-rate of 20% for indirect herniæ and 25% for direct herniæ.

McPherson, 1943—174 cases, treated mainly by herniotomy or Gallie's operation, with a total recurrence-rate of 14 9%—indirect 12%, direct (17 cases) 35 3%

Discussion

The criterion of a recurrent hernia was considered to be the presence of an expansile cough impulse. It has not seemed reasonable to defer diagnosing recurrent hernia until this caused disability indeed, in this series over 10% of recurrences were unnoticed by the patient. Asymptomatic recurrences make reviews which are not based on physical examination liable to error

The persistence of a high recurrence rate is disturbing, and we feel that this series reveals features which could point the way to better results

Type of Operation

Case-histories were inadequate to correlate the type of operation with the state of the posterior wall of the inguinal canal Where, however, a repair has been considered necessary, the best results appear to follow the nylon-darn, now commonly used in place of the Gallie, and the Bloodgood types of techniques Unfortunately there were too few of the latter to allow a firm conclusion to be made. The Bassini operation has been associated with a high incidence of recurrence at this hospital, but the figures are too small to determine whether the results varied with the suture materials used.

Priority

Inguinal herniæ are often relegated to the end of the list and are too often done by inexperienced operators without adequate supervision. The recurrence-rate for indirect herniæ operated on by housemen was 20%, compared with 9% by registrars

The high incidence of recurrence following herniotomy alone can be partly ascribed to bad choice of operation, as many as a third being done on patients between the ages of 40 and 59 In this series simple herniotomy has a low recurrence-rate up to the age of 39, after which it rises steeply

It is also difficult to escape the conclusion that the remarkable results obtained on recurrent herniæ are partly related to the extra care which is called forth by these herniæ.

Further information acquired from this series confirms that postoperative sepsis is associated with an increased recurrence-rate, and that neither simultaneous repair of bilateral herniæ nor ambulation during the first postoperative week influences recurrence-rate Almost all recurrences were diagnosed within four years of operation, the majority showed themselves by the end of the first year

The results did not show an increasing liability to recurrence with increasing age of the patient, but "invisible" factors were at work here for example, the younger patients with the simpler herniæ were mainly operated on by younger surgeons

There was 1 sinus following the nylon darn repair

It was not possible to determine whether prophylactic postoperative administration of antibiotics or sulphonamides influenced the sepsis-rate

Conclusion

The results of this review are disappointing Being the unselected results of a number of different surgeons, they probably represent the state of affairs in most hospitals where the treatment of herniæ is given similar priority

Greater attention to the care of these patients is likely to improve results The final decision as to which operation should be performed should be made when the tissues are exposed at operation, and only by someone with experience

The nylon darn and Bloodgood types of operation have given good results Simple herniotomy for patients with a sound posterior wall gave low recurrence-rates up to the age of 39 The Bassini operation, although apparently successful in certain hands, does not appear to give good results at this hospital

Our thanks are due to the surgeons at St. Thomas's Hospital for permission to carry out this investigation, and to the staff of the Medical Branch, Scotland Yard, for help in tracing the patients

LEISHMANIASIS ACQUIRED BY CONTAGION

A CASE OF MARITAL INFECTION IN BRITAIN

W St C Symmers
M.D Belf, F.R C.P
PROFESSOR OF MORBID ANATOMY IN THE UNIVERSITY OF LONDON
AT CHARING CROSS HOSPITAL MEDICAL SCHOOL, W C.2

The transmission of all forms of leishmaniasis depends ordinarily upon phlebotomus sandflies We owe our freedom from the infection in this country to our climate, which does not suit the insect vectors, and to the absence of any reservoir of infection in the population or in animals The occasional cases which we see originate elsewhere—most of them are examples of the so-called oriental sore, and the diagnosis is readily made when the patient is known to have come from a part of the world where this disease occurs A knowledge of geographical pathology and of the symptomatology of exotic diseases is becoming more and more important as travel becomes easier, faster, and more necessary, and the diagnostic importance of taking an accurate history of patients' oversea journeyings is obvious

The American Geographical Society's (1954) map of the world distribution of leishmanial infections shows that *cutaneous leishmaniasis* (oriental sore) occurs in parts of Europe, Africa, and Asia It is found in the coastal belt of the countries of the whole Mediterranean basin, across Turkey to the Caspian Sea, down through Iraq to the Persian Gulf, across Iran, Afghani-

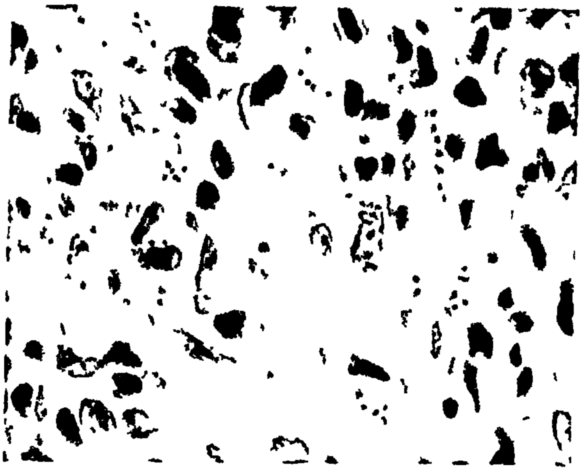

Fig 1—Biopsy of vulvar lesion the leishmanias in the macrophages of the inflammatory exudate are easily seen (Hæmatoxylin-eosin; × 600)

stan, and Turkistan, across Pakistan and northern India, and in Ceylon It occurs in West Africa from the Gambia to the Cameroons, and in East Africa—particularly in Ethiopia Occasional cases have been recognised in other parts of West and East Africa, in Malaya, and in various parts of eastern Asia Isolated cases have also been reported nearer Britain, in Portugal and northern Spain

It is not proposed to refer particularly to *visceral leishmaniasis* (kala-azar) or to *American leishmaniasis* in this paper It may be noted, however, that the geographical distribution of visceral leishmaniasis is a good deal wider than is usually realised, and yet overlaps remarkably little with that of oriental sore An account of leishmaniasis in all its forms is readily accessible in *Manson's Tropical Diseases* (Manson-Bahr 1954), and only some aspects relevant to the cases reported in this paper will be mentioned here

Cases of cutaneous leishmaniasis have been reported in Britain from time to time, and particularly since the late war (Conrad et al 1950, Howell 1957, and others, including cases shown at society meetings, and particularly at the Section of Dermatology of the Royal Society of Medicine) The patients have usually been visitors or immigrants from areas where the disease is endemic From the geographical summary given above it may be seen that some of these areas are commonly enough visited by British businessfolk or holidaymakers, the diagnosis of cutaneous leishmaniasis is worth considering when any patient with an indolent skin lesion has been in such parts The length of stay in an endemic area before infection takes place need be no longer than the few moments taken by a sandfly to feed

The protozoon which causes leishmaniasis was first recognised in a soldier who had come home to this country from India

Leishman (1903) found the organism, in 1900, in smears from the spleen of this man, who had died of kala-azar in the Royal Victoria Hospital in Netley, Hampshire The patient had contracted the disease during service in Dum Dum, the station in Bengal which gave the disease one of its names Publication of Leishman's (1903) observation led Donovan (1903) to record his own independent discovery of the organism, which he had found in Madras in 1903 in smears from the spleens of three patients at necropsy and of one living patient It is appropriate that the names of these two men are coupled in the common designation of the parasites as Leishman-Donovan bodies and in the name of the most important species, *Leishmania donovani* Wright's (1903) discovery of the causative organism of oriental sore, now known as *L tropica*, followed shortly afterwards The other main varieties of *Leishmania* are *L infantum*, which causes visceral leishmaniasis of children on the Mediterranean littoral, and *L brasiliensis*, the cause of American leishmaniasis In addition, mention must be made of *L canis*, which causes leishmaniasis in dogs, particularly in Mediterranean lands but also elsewhere—the infection has, for instance, been found in dogs in the region of Paris (Guilhon 1950) and in Brittany (Guilhon and Loge 1950) It has been suggested that canine leishmaniasis may be a reservoir for human infection There is some doubt whether all these named species of *Leishmania* really qualify to be considered as specifically distinct from one another

The main purpose of this paper is to report a case of leishmaniasis which is unprecedented in that the patient had never been out of the British Isles before she acquired her infection Her case was also remarkable in that the lesion, which was on the vulva, was almost certainly the result of direct contagion her husband had a symptomless recurrence of visceral leishmaniasis contracted several years earlier in north-eastern Africa As the clinical and laboratory management of her case was bedevilled by a series of avoidable mistakes, before the correct diagnosis was made, it may be politic to make known that the investigations and treatment were carried out in hospitals and laboratories which are not in London, and that she developed the lesion in 1955 Both patients know the full circumstances of the mistakes made, and they and the doctors concerned have encouraged publication of this account

Case-records

A woman, aged 38, noticed a small, rather itchy papule a little behind the vaginal orifice and to one side of the midline As it was enlarging she went to her doctor—her husband's brother—a month later The lesion was then a shiny, purple, dome-shaped nodule, a centimetre in diameter, painless, and with a small, central excoriation which the patient attributed to chafing by sanitary towels Nothing was done about the lesion at that time A month later it was almost twice as large the central erosion had become a round, sharply outlined, steep sided but quite shallow ulcer, about a centimetre across, with a grey base There was now a group of moderately enlarged, firm, painless, lymph-nodes medially in the groin on the same side Her doctor diagnosed primary syphilis although he had never seen a chancre at that time

Blood for a Wassermann reaction was sent to a laboratory where, it so happened, it was still the practice for the entire Wassermann procedure to be carried out by the pathologists Unfortunately, the senior registrar whose turn it was to do the Wassermann tests had no previous experience of complement fixation techniques, and as he had just been newly appointed to his job he did not like to admit to this gap in his training It has become clear that in this patient's case he must have either misconducted the test or misinterpreted its result, which was reported to her doctor as positive

The patient was then seen by a gynæcologist, who agreed that the lesion could be syphilitic and recommended appropriate treatment He did in fact say that the Wassermann reaction should be repeated and a Kahn test done as a confirmatory precaution before treatment was started, but this advice was overlooked and a month's course of penicillin was begun without further ado The patient had never had treatment with penicillin before During the last few days of the course she felt unwell she became somewhat feverish and developed joint pains and an erythematous rash on her face and body The significance of this syndrome was not realised at the time, but it was almost certainly a reaction to penicillin, to which she is now known to have become sensitive Her Wassermann reaction becomes positive whenever a penicillin reaction is provoked (her Kahn-test result is negative at all times) This may explain why the Wassermann reaction at the end of the month's course of penicillin was reported (this time, by chance, in a different laboratory) as "+ ±", the Kahn test, done then for the first time, was negative.

Although by then the local lymphadenopathy had disappeared the vulvar sore was larger than before the course of penicillin. For some reason which is no longer clear a darkfield examination was carried out now, for the first time, it was reported as negative.

Both the patient and her husband denied having had sexual intercourse with anyone else. As the husband had no genital lesions and his Wassermann and Kahn reactions were negative his wife's truthfulness seemed to be in doubt, he left home. Fortunately, it was at last beginning to be realised that there was something inconsistent between the clinical findings and the supposed diagnosis of syphilis. Biopsy of the ulcer was therefore carried out, five weeks after the end of the course of penicillin and eighteen weeks after the patient first noticed the lesion.

The sections showed a chronic inflammatory reaction in the dermis, nondescript for the most part but with a small area in which typical Leishman-Donovan bodies were readily recognised within macrophages (fig 1). Their presence was confirmed in stained films of exudate from the ulcer (fig 2), and they were also well demonstrated by darkfield examination. When the technician who had been entrusted with the first darkfield examination was shown the leishmanias in the later preparation he recognised at once that he had seen them in the earlier specimen. He explained that he had not drawn anyone's attention to them because he had only been told to look for treponemas. Attempts were made to cultivate the organism from fluid obtained by puncture of the unbroken skin over the periphery of the lesion; they failed because of bacterial contamination.

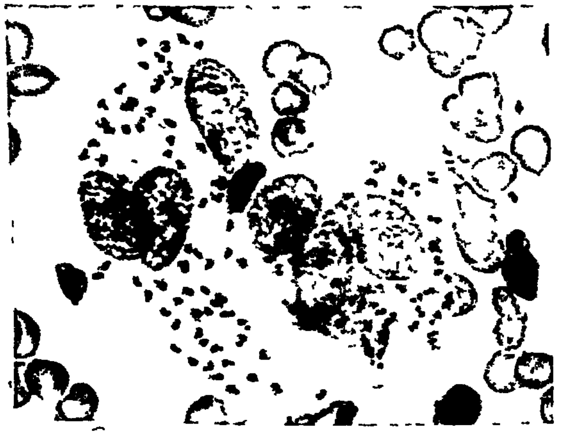

Fig 2—A group of leishmania-laden macrophages in a film of exudate from the vulvar lesion (Leishman's stain, ×900.)

As the patient had never been out of the British Isles it was necessary to consider various seemingly unlikely ways by which she could have become infected. There was no immediately obvious solution of this mystery, although all sorts of possible sources of infected vectors were looked for in her environment. By this time it had been possible to get in touch again with her husband, who had gone abroad; he returned home at once with the answer, which unwittingly he had all along possessed, in the form of a history of kala-azar. He had contracted kala-azar while on service in the Sudan, Ethiopia, and Uganda in 1941 or thereabouts. This had been only erratically treated, owing to the exigencies of the times and of his work, and, later, of detention as a prisoner-of-war. The drugs used were probably antimony potassium tartrate and ethylstibamine ('Neostibosan'). By 1944 he was pronounced cured, only to develop typical post-kala-azar dermal leishmaniasis a year later. This in its turn cleared up on treatment with pentamidine isethionate ('Lomidine'), and from then onwards he was free from all symptoms. He married in 1953, eight years later. His wife's leishmanial ulcer developed in 1955, two years after their marriage.

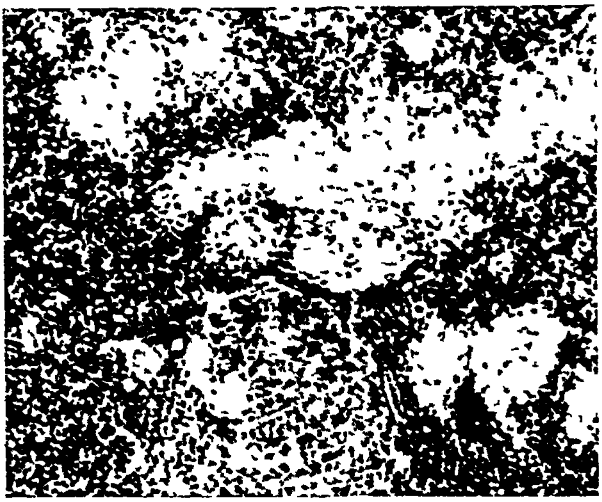

Fig 3—Focal histiocytosis in lymph-node biopsy specimen from the husband of the patient whose infection is illustrated in figs 1 and 2. (Hæmatoxylin-eosin, ×150.)

Although at this time he was completely symptomless and for ten years had been aware of nothing amiss with his health, examination showed that the tip of his spleen was palpable four centimetres below the costal margin, his liver was palpable a centimetre below the costal margin, and there was generalised lymph-node enlargement. It seems likely that a complete physical examination instead of the perfunctory inspection of his genitalia at the time when his doctor looked for evidence of syphilis could have led to a prompt appreciation of the true condition of his health and of the nature of his wife's ulcer. When examined he was afebrile. The serum-protein levels were normal. Napier's formol-gel test and the urea-stibamine test were negative. Apart from slight granulocytopenia his blood was normal. The marrow was not examined. Biopsy of an axillary lymph-node showed many discrete, small foci of histiocytosis (fig 3); it was evident that the histiocytes contained minute particles, and at higher magnifications these were clearly recognisable as leishmanias (figs 4a and b). They were well seen in films of fluid from the node, and they were successfully cultivated in "NNN" (Novy, MacNeal, and Nicolle medium), in which typical flagellate forms ("leptomonads") developed abundantly within five days on incubation at 22°C. He was treated with pentamidine isethionate (0·2 g intravenously daily for ten days). A month later there was no detectable clinical abnormality, and this is his present state. Before the course of treatment attempts were made repeatedly but unsuccessfully to demonstrate leishmanias in his urine, prostatic secretion, and semen.

The woman's lesion healed satisfactorily when she was given a course of urea stibamine (0·2 g intravenously daily for ten days); it has not recurred (January, 1960). She and her husband have re-established their home and have had their first child, which was born uneventfully eighteen months after cure of the ulcer.

Discussion

Clinicopathological Management

There is no need to discuss the reasons for the mistakes in the investigation and management of the woman's case. Although it is understandable how medical training nowadays might be completed without the student having an opportunity to see a primary syphilitic chancre, it is disquieting that any doctor could consider a single positive report of a single serological test as adequate grounds for telling a patient and her husband that she had syphilis, with all the potential implications and consequences. It is unfortunate that the gynæcologist should have prescribed treatment for primary syphilis without asking

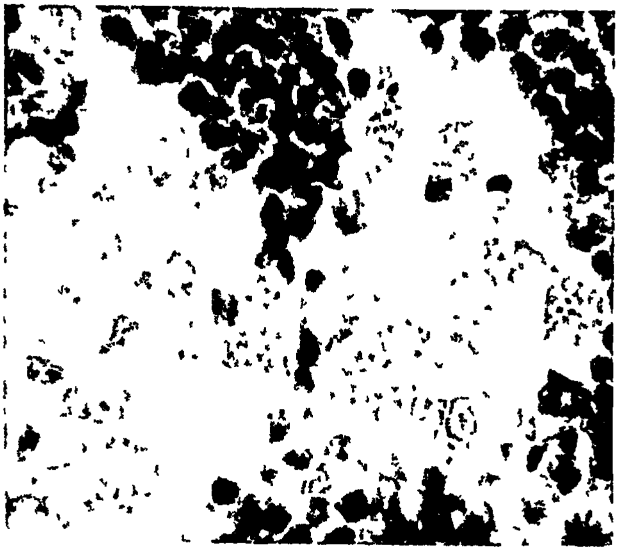

Fig 4a—Higher magnification of a field like that in fig 3 (same preparation): the leishmanias can be seen in the pale cytoplasm of the histiocytes (Hæmatoxylin-eosin, ×650.)

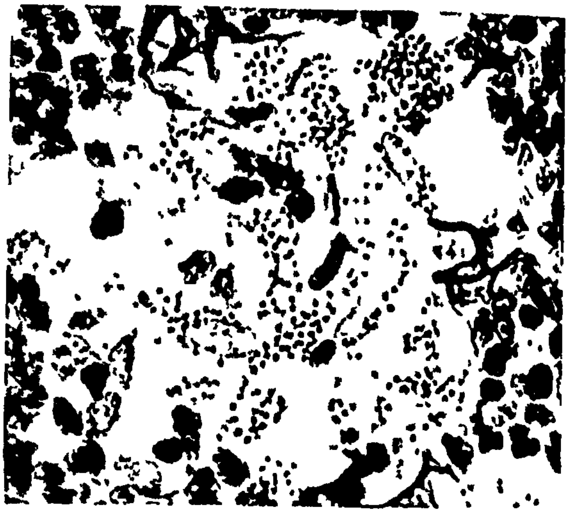

Fig 4b—A field comparable to fig 4a, but from a silvered preparation in which the parasites are more obvious although the details of their structure are obscured (Robb-Smith [1937] method for reticulin; ×650.)

for darkfield investigations in addition to the confirmatory blood tests. In any case, to neglect nowadays such a clear indication for the *Treponema pallidum* immobilisation test is a major oversight.

It was interesting that the conduct of the pathological investigations should have disclosed two extremes in modern laboratory practice. In one laboratory the actual interpretation of darkfield examinations was delegated to a technician, in the other laboratory the pathologists personally undertook every step in the performance of the Wassermann reaction and not merely the interpretation of the results. Paradoxically, in the laboratory in which there was this insistence on the pathologists' personal responsibility for carrying out the Wassermann procedure it was not regularly the practice to put up parallel confirmatory tests unless the Kahn test was specifically asked for, which was not done in this case.

Latent Recurrent Kala-azar

I have not been able to find any previous instance of a recurrence of visceral leishmaniasis so long after what had been considered successful treatment. The patient's freedom from symptoms was another exceptional feature of his recurrent infection.

The histological pattern shown by the lymph-node biopsy was precisely that seen in cases of acquired toxoplasmic lymphadenitis in adults (Bang 1957, Piringer-Kuchinka et al 1958). Only the presence of the leishmanias distinguished the picture from that of toxoplasmosis, the morphological characteristics of the organisms under the oil-immersion objective were unmistakable. In some cases it can be difficult to distinguish confidently in hæmatoxylin-eosin preparations between leishmanias and other particulate bodies, particularly *Histoplasma capsulatum* (Woo and Reimann 1957). Recently, in a personal observation, groups of the small-spore form of *Blastomyces brasiliensis*, separated from their parent yeasts and engulfed by macrophages, were mistaken for *Leishmania brasiliensis* in a biopsy specimen, the lesion was a mucocutaneous granuloma which developed some months after the patient had returned home to this country following a year's stay in Brazil. The well-known Flemming bodies (particulate nuclear debris) in lymphoid follicles, which are notoriously liable to be mistaken for histoplasmas, may also be misinterpreted as leishmanias. Romanowsky stains are not as helpful in identifying leishmanias in histological preparations as they are in films the periodic-acid/Schiff reaction is often more useful, readily distinguishing fungi like histoplasma from leishmanias (leishmanias may contain particles which give this reaction, but these are minute, and confusion should not result). In all cases in which it is possible—and that should be the vast majority—film preparations should be made whenever the diagnosis of leishmaniasis is considered, for they will readily enable any leishmanias which are present to be correctly recognised.

Excision of lymph-nodes for the diagnosis of leishmaniasis was advocated many years ago by Cochran (1912), who, however, recommended this procedure merely so that films could be made from them. Cole (1943–44) reviewed 60 cases of kala-azar in the Kapoeta area of East Africa, this is the area where Ethiopia, Kenya, and Uganda meet, and it was probably here that the man whose case is recorded above became infected. Cole mentioned that half of his patients showed lymph-node enlargement, usually in the inguinal and femoral groups. In one case, indeed, lymphadenopathy was the presenting manifestation, leishmanias were found by lymph-node puncture in 12 out of 27 cases in which this investigation was carried out. Kirk and Sati (1939–40) demonstrated the organisms in films of juice obtained by needling apparently normal lymph-nodes in Sudanese cases of kala-azar. Cole (1943–44) found urea stibamine to be the most effective drug in his cases. Post-kala-azar dermal leishmaniasis developed in 17 of the 38 patients in his series who survived, the parasites were demonstrated in scrapings from the skin lesions in 8 out of 12 cases investigated. During the period in which he studied the 60 cases of visceral infection he saw only 1 case of oriental sore.

In contrast with cases in the Sudan, where Kirk and Sati (1939–40, 1940–41) found that there is often no latent period between visceral involvement and involvement of the skin and lymph-nodes, Napier (1935) found in India that the organisms can scarcely ever be demonstrated in the skin and lymph-nodes during the visceral stage of kala-azar. Post-kala-azar dermal leishmaniasis, which was first described by Brahmachari (1922), usually appears a year or two after the visceral disease has subsided, and particularly in cases in which the latter has been inadequately treated it is easily distinguishable clinically from oriental sore, differing from this condition specially in its more widespread involvement of the skin and in the multiplicity of the lesions, which are commonly nodular. In view of the lymph-node involvement in the case reported in this paper, and of the patient's earlier history of post-kala-azar dermal leishmaniasis, it is interesting to learn that both leishmanial lymphadenitis and post-kala-azar dermal leishmaniasis are seen more frequently in north-east Africa than in other parts of the world.

It is remarkable that the woman's lesion took the form of an oriental sore, typical of infection by *L tropica*, whereas her husband's disease was of the visceral type associated with infection by *L donovani* Shapiro and Btesh (1939–40) mentioned the case of an Arab child in Palestine who simultaneously had kala-azar and cutaneous leishmaniasis of the oriental-sore type they raised the question whether this boy was doubly infected with *L donovani* and *L tropica* or whether *L donovani* was the cause of both the visceral and the cutaneous disease It would have been instructive in this woman's case to know whether the transitory inguinal lymph-node enlargement was due to leishmanial infection, as was her husband's lymphadenopathy, or whether it was unspecific

Transmission of leishmaniasis

There seems to be no doubt that the infection in this case was passed by sexual intercourse There are very few acceptable reported instances of person-to-person leishmanial infection and none of transmission by contagion

One foreign author cites Leishman as his authority for stating that the disease can be spread venereally I have been unable to trace such a statement in any of Leishman's writings, and it seems possible that a comment which he made when writing about the ætiology of kala-azar has been misread "In the presence of these important gaps in our knowledge of the life-cycle of the parasite any description of the ætiology of the disease must be, in the main, speculative There appears to be little doubt that the disease is spread by human intercourse, though not by direct 'contagion' in its strict sense" (Leishman 1912) It is clear that sexual intercourse was not implied

Shortt (1945–46) reviewed the ways in which leishmaniasis might be spread, and he noted that person-to-person transmission was theoretically possible The organisms may be present in a viable state in nasal secretion and in urine, and they can survive for a day or more in moist soil and for several days in milk. They also appear to be able to withstand desiccation for a few hours Shortt pointed out that infection can be shown by experiment to follow introduction of the parasite into the mouth or conjunctival sac, thus indicating the possibility of transmission by ingestion or by droplet infection.

Firth (1912) and Berberian (1939–40) reviewed the deliberate, and often traditional, practice of inoculating children and others with oriental sore in order to provide some measure of immunity and to try to ensure that the often unsightly scar of the healed lesion should be in an inconspicuous site There is no doubt that under these conditions person-to-person infection can occur Under natural conditions, however, leishmania requires to spend a part of its life-cycle within the body of the phlebotomus vector, undergoing metamorphosis and multiplying before the fly can transmit the infection to a fresh victim It may be noted that Leishman's (1912) remarks on the ætiology of the disease, quoted above, were written before Mackie's (1915) suggestions about the role of the sandfly as vector, and long before it was finally proved that the infected flies could in fact transmit the disease Adler (1939–40) successfully transmitted kala-azar to one of five patients with advanced malignant disease whom he inoculated with cultures of *L donovani* the incubation period was uncertain but did not exceed five months Later, Swaminath et al (1942) transmitted Indian kala-azar to man by the bite of infected sandflies in each of five experiments the incubation period was between nineteen and thirty weeks or thereabouts Other experimental studies have confirmed that leishmaniasis can be conveyed in this way, provided that enough time is allowed for the protozoon to complete its cycle of development in the infected phlebotomus before attempting to transmit the infection, and provided that the inoculated volunteers or animals are kept under observation long enough to allow the presence of infection to be recognised There is no longer any doubt that natural infections with leishmania, including familial and household infections, are ordinarily attributable to the bite of infected sandflies

Senekji and Beattie (1940–41) studied the development of experimentally produced oriental sores in man From observations on over 200 cases they found that the incubation period after an intradermal injection of three million leptomonad forms from cultures of *L tropica* ranged from under two weeks to eight weeks A single inoculation was sufficient to produce infection in over 99% of their experiments In the average case a macule appeared at the site of inoculation after three weeks and gradually developed into a slightly scaly, purplish papule with an infiltrated base in six months the lesion was as large as a "coffee bean" In half the cases ulceration occurred after six to eight months, and the untreated ulcers took nine months to a year to heal Ulceration was thought to result from incidental traumatisation of the lesion. These observations correspond closely to the patient's account of the development of the vulvar lesion in the case described here The incubation period in her case cannot be estimated Manson-Bahr (1954) mentioned that the incubation period of oriental sore is variously stated in days, weeks, or months, periods of three years (Smith 1955) and three and a half years (Fidler 1952) have also been recorded.

Two other methods of transmission deserve mention Transplacental infection of the fœtus can occur (Hindle 1928, Banerji 1955), Low and Cooke (1926) described a case of congenital leishmaniasis in a child, born in Britain, whose mother had become infected while in India Blood has also been the vehicle of infection in other circumstances Chung et al (1948) recorded the development of kala-azar nine months and ten months after two children had each had an intramuscular injection of 20 ml of their mother's whole blood as a prophylactic against measles the mother's infection by leishmania was recognised soon after she had given the blood André et al (1957) reported a case in France of visceral leishmaniasis in a baby who received at birth an exsanguination transfusion of blood from a donor who had leishmaniasis of the skin and lymph-nodes

A case of accidental infection with *L donovani*, in a laboratory worker, has been recorded (Terry et al 1950) The finger which was infected had been bitten on several occasions by experimentally infected animals

Other Cases

All the other four cases of leishmanial infection which I have seen during the past five years presented as typical examples of so-called oriental sores The lesion was solitary in each case

Two of the patients were children from Cyprus—both were at school in England when the diagnosis was made, but in each case the lesion, which was on the forehead, had already begun to appear when the child left home, six months and eight months earlier The boys came from different parts of the island, one was Greek and the other Turkish

In the third case there was also presumptive evidence that the infection was contracted in Cyprus The patient was a doctor who spent nine months in the island, he had never been elsewhere abroad, and he had travelled to and from Cyprus without stopping en route His lesion was on the back of one hand and first appeared as a macule about five months after his return to England

The fourth patient was a young woman who had never been out of England until she went on a bicycle trip to the South of France, where she spent five days camping in the Languedoc not far from Montpellier She was away from home for altogether fourteen days Her leishmanial granuloma was on one knee and was first noticed as a little pimple-like lesion five weeks after she left France ulceration followed within ten days Autochthonous cases of cutaneous leishmaniasis in southern France have been reported on a number of occasions (Rimbaud et al 1958)

Diagnosis was made by biopsy in each of these cases and confirmed by examining films of fluid obtained from the lesion Cultivation was not attempted Each patient was given a course of injections of one or another of the quinquevalent antimony preparations which are in current use The lesions healed satisfactorily, except for the usual residual scarring

Summary

A case of cutaneous leishmaniasis occurring in Britain and resulting from marital intercourse is reported

The lesion, on the vulva, was at first mistaken for a primary syphilitic chancre The correct diagnosis was made by biopsy The patient's husband was found to have a symptomless recurrence of visceral leishmaniasis, which he had contracted in north-eastern Africa fourteen years earlier Transmission of leishmanial infection by contagion is extremely rare

Four typical examples of so-called oriental sore were seen in Britain during the past five years In three cases the infection was contracted in Cyprus, and in the fourth case in the South of France

PREVENTION OF MIGRAINE IN CHILDREN BY PROCHLORPERAZINE

R S ILLINGWORTH
M D Leeds, F R C P, D P H, D C H
PROFESSOR OF CHILD HEALTH, UNIVERSITY OF SHEFFIELD

C C HARVEY
M D Lond, B Sc, M R C P, F R C S E
PÆDIATRICIAN, WEST RIDING COUNTY COUNCIL, CLINICAL TEACHER, DEPARTMENT OF CHILD HEALTH, UNIVERSITY OF SHEFFIELD

A DOUBLE-BLIND trial is a satisfactory way of assessing the value of a drug in a condition of such varying severity as migraine In view of the claims made for the value of prochlorperazine ('Stemetil') in the prevention of migraine (Leyton 1957, Schaefer 1959) we have conducted a double blind trial in order to assess its value

Method and Material

Selection of Cases

All children were seen by us at the Children's Hospital, Sheffield, or the Rotherham and Mexborough Hospitals and county pædiatric clinics All had the classical picture of migraine, with a family history of the same complaint Children with headaches alone, without the associated symptoms, were excluded Only those who had had frequent attacks over a long period, not less often than about once a month, were included

The double-blind method was adopted The makers of the drug kindly supplied placebo, or control, tablets Having made the diagnosis we prescribed the drug, and the pharmacist, by random sampling, supplied either the active drug or the control When we saw the child again and repeated the prescription, the pharmacist supplied the opposite of that supplied previously Only after we had studied enough patients and tabulated the results based on the parents' opinion did we receive the code which indicated the order in which the active tablet and the control tablet were prescribed

We used a simple scoring method before receiving the code This consisted of −3 to +3 −3 would mean that the patient was much worse +3 would mean that he was much better +2 meant that he was "better" +1 meant that he was slightly better

32 patients were studied, but some failed to come a second time, so the change-over of drugs could not be effected 28 patients received the active drug, and 29 received the control

The dosage was that recommended by the makers This was $2^{1}/_{2}$ mg twice a day for children $2^{1}/_{2}$ years of age, 5 mg b d at the age of 5 years, and $7^{1}/_{2}$ mg b d at the age of 10 years

Results

The 28 patients receiving the active drug scored +39 (see table) The 29 patients receiving the placebo scored +43

SCORES ALLOTTED ON THE ACTIVE AND CONTROL TABLETS

Score	No achieving score	
	Control tablet	Active drug
+3	8	6
+2	8	9
+1	5	4
0	7	8
−1	1	1
−2	0	0
−3	0	0

It will be seen that there was no difference between the two groups The placebo relieved many of the children

There were no toxic effects One mother said that the medicine made her child sick, the offending material was the inert tablet

Summary

In a double-blind trial of prochlorperazine for the prevention of migraine in children, the drug proved no more effective than an inert control tablet The inert tablet relieved many children of their attacks

In the dosage used, prochlorperazine was not of value in the prevention of migraine in children

Our thanks are due to Miss C I Crawford, chief pharmacist, for her help in this experiment, and to Messrs May and Baker for supplying the tablets and control material, and for their advice and help

IN many reported series of subarachnoid hæmorrhage there are factors of selection for which allowance cannot be made Necropsy studies can never be representative, and series from general hospitals often exclude patients who die suddenly or in the first few hours after admission Neurosurgical series are usually biased by exclusion of these early deaths, or by inclusion of patients solely because of recurrent hæmorrhage This study is an attempt to define more accurately certain features of the acute stage of subarachnoid hæmorrhage in young adults, for it is against this background that the results of neurosurgery must be set

Method of Investigation

We have reviewed the records of all Army patients diagnosed during the seven years 1950–56 as having spontaneous intracranial hæmorrhage, intracranial aneurysm, or angioma Hæmorrhage secondary to blood-disease or tumour was not included 10 cases were rejected—5 because of insufficient evidence of subarachnoid hæmorrhage, 2 because there was no recent hæmorrhage, 2 because of inadequate clinical records, and 1 as a case of hypertensive cerebral hæmorrhage in a man over fifty-five years of age 103 cases remained The presence of subarachnoid hæmorrhage was proved by examination of the cerebrospinal fluid in 68 cases, by necropsy in 15, and by both in 20 All but a very few cases were followed for eight weeks from the onset of the illness This period alone—the acute stage—will be considered here

Classification of Cases

There is good evidence (Walton 1956, and others) that the prognosis in subarachnoid hæmorrhage is closely related to certain features of the early stages of the illness Our cases were assessed according to their state on first admission to hospital, by applying the classification of Smith and Vollum (1956) for tuberculous meningitis

TABLE I—AGE-INCIDENCE

Age (yr)	18–19	20–24	25–29	30–34	35–39	40–44	45–49	50 +	Total
No of cases	31	35	7	9	10	5	5	1	103
Average annual incidence per 1000 at risk	0·03	0 04	0·05		0·07		0 12		0 04

Group 1 includes those who were fully conscious and rational, with no abnormal neurological signs beyond those of meningeal irritation

Group 3 includes all patients who were comatose or completely inaccessible, or who had a complete hemiplegia

Group 2 is intermediate, and includes those with abnormal neurological signs (excluding complete hemiplegia), and those who, despite alteration of consciousness, could still communicate with the examiner

Group 4 comprises all patients who died before admission to hospital These are included to complete the natural history of a condition which is one of the commoner causes of sudden death in young adults

The course of the illness was classified according to a modification of a scheme proposed by Holmes (1957)

TABLE III—RELATION OF CLINICAL GROUP TO COURSE OF ILLNESS

Course	Death				Recovery	Total
	Deterioration		Recurrence		Steady recovery	
	Rapid*	Slow	Fatal	Non-fatal		
Clinical group 1	3 } (5 5%)	2	7	4	32	48
,, ,, 2	1 }	3	1	2	18	25
,, ,, 3	7 (35%)	1	4	1	7	20
Total	11	6	12	7	57	93

* All 10 patients in group 4 showed rapid fatal deterioration

The course may be one of deterioration, either rapid (with death within forty-eight hours) or slow (with death within fourteen days), without evidence of further hæmorrhage, or initial improvement may be followed by recurrent bleeding, fatal or non-fatal, or recovery may be steady and uninterrupted

Results

Of the 103 cases, 79 were first admitted to military hospitals (43 overseas, 36 in the United Kingdom) and 24 to civilian hospitals (1 overseas, 23 in the United Kingdom) 84 patients were admitted on the first day of the illness, 8 on the second, 4 on the third, 6 on the fourth to sixth days, and 1 (a case of so-called " pseudo-tumour syndrome ") in the third week

Table I shows the cases grouped according to age, and the average incidence per 1000 at risk per year The incidence rises steadily with age, and is four times as great at ages over forty-five as at under twenty, although the number in the former group is small

Table II shows the distribution of cases by age in each clinical group, and the mortality in the first eight weeks Mortality increases with age, and is significantly greater over the age of thirty (63%) than under (27%) (Here, and later, significance is taken at the 1% level) The proportion of cases in group 4 is higher among the older patients, and the mortality is higher, irrespective of the initial clinical state, compared with the younger age-group

TABLE II—MORTALITY BY AGE AND CLINICAL GROUP

Age (yr)	18–19	20–24	25–29	30–34	35–39	40–44	45–49	50 –	Total under 30	Total over 30	Total
Clinical group 1	2/16	3 15	0 3	1/4	3/5	0 1	2/3	1/1	} 9/55 (16%)	} 8/18 (44%)	} 17/73 (23%)

TABLE IV—RELATION OF RECURRENCE AND DEATH TO LENGTH OF ILLNESS

Week after onset	1					2			3	4	5+
Day after onset	1	2	3	4	5	6–8	9–11	12–14	15–21	22–28	29+
Patients at risk	103	88	82	82	79	78	78	77	73	70	66
No of deaths	15	6	0	3	1	0	1	4	3	4	2
Deaths (% per day)	14 6	6 8	0	3 7	1 2	0	0 4	1 8	0 6	0 8	—
No of recurrences	—	—	—	2	0	1	2	2	5	1	5
Recurrences (% per day)	—	—	—	2 5	0	0 4	0 8	0 9	1 0	0 8	—

Table III shows that the significantly greater death-rate among cases in group 3 (60%, as against 23% in groups 1 and 2 together) is due to many more deaths in the first forty-eight hours of the illness The condition of 35% of cases in group 3 deteriorated rapidly, but this is true of only 5 5% of cases in groups 1 and 2 The recurrence-rate is 38% in group 3, and 20% in groups 1 and 2 combined, a difference which is not significant Recurrent bleeding carries a higher mortality than the first hæmorrhage 12 of 19 recurrences were fatal, as against 27 of 103 first hæmorrhages The mortality of recurrent bleeding is also greater in group 3 (80%) than in groups 1 and 2 combined (57%)

The distribution of deaths and recurrences over the first eight weeks of the illness is shown in table IV Death is common in the first five days, but uncommon thereafter Recurrences after the first few days are at a steady rate

Of 58 patients transferred to other hospitals after first admission, 32 were transferred in the first four weeks—9 by air and 23 by road 1 patient's condition deteriorated during flight, perhaps because of heavy sedation 2 other cases, transferred after the first four weeks, also became worse in transit, in both there was probably mild recurrent bleeding In no other case did transport in the acute stage appear to aggravate the patient's condition, despite the long and often arduous journeys undertaken

47 of the 58 patients transferred to neurological units underwent bilateral carotid angiography 24 angiograms were abnormal Of the 11 remaining patients 2 died and were found at necropsy to have intracranial aneurysms Of the angiographic abnormalities 15 were aneurysms, 6 angiomata, and 3 of uncertain nature Thus carotid angiography showed a probable source of bleeding in only 44% of cases investigated

Discussion

In general our findings agree with those of others The incidence of subarachnoid hæmorrhage is found to increase with age, at least up to sixty (Helpern and Rabson 1950, Walton 1956) Although the Service population, from which our cases are drawn, is highly selected by exclusion of the physically unfit, such selection is unlikely to operate against subarachnoid hæmorrhage (the cause of which is usually latent), except for a few cases with migraine and epilepsy We therefore regard the annual incidence given in table I as approximately that in the population of the United Kingdom

That mortality increases with age (Richardson and Hyland 1941, Walton 1956) can be shown even below the age of thirty (table II) The figure of 27% for the death-rate of our patients under thirty may be compared with figures of 31% (Richardson and Hyland 1941) and 27% (Walton 1956), although neither of these series included cases dead on admission Our figure of 63% mortality for patients over thirty is higher than that given by others, but is based on small numbers

Despite the differences in underlying pathology, clinical grouping derived from that used for tuberculous meningitis can be applied satisfactorily to subarachnoid hæmorrhage, as our findings show The general conclusion to be drawn from tables II and III is that, apart from age, the principal prognostic sign is the severity and duration of the disturbance of consciousness, rather than the presence or absence of focal neurological signs (unless there is complete hemiplegia) Thus, hæmorrhage sufficient to cause deep coma on admission carried a mortality of 35% in the first forty-eight hours whereas lesser hæmorrhages, whatever mental disturbance or neurological signs they produced, were fatal in only 5% in the same period Although the incidence of recurrent hæmorrhage is the same in all cases if they survive forty-eight hours, the mortality-rate of recurrences is higher in those who have had severe initial hæmorrhage

Magee (1943) showed that the peak incidence of recurrence is in the second to fourth week of illness Others have confirmed this (see particularly McKissock and Walsh 1956) In our cases there were only 3 recurrences and 2 deaths between the fifth and eleventh days inclusive, and the highest incidence of fatal recurrence was between the twelfth and fourteenth days If surgery is to prevent these recurrences, clearly it must be undertaken before the end of the second week Although angiography is probably more hazardous (Falconer 1954) and less likely to disclose underlying aneurysms (Magladery 1955) if performed in the first few days of the illness than later, the need for information on which to plan surgery seems to justify its being undertaken early (McKissock and Walsh 1956)

A further group of patients for whom surgery may have something to offer is those whose condition deteriorates slowly (Holmes 1957) In Holmes' series (of 100 cases in all) 23 of 43 patients died in this way, but in our series only 6 of 29 The reason for this difference is not clear, but possibly in Holmes' older patients more deaths were due to the sequelæ of prolonged unconsciousness (such as bronchopneumonia) and to the metabolic effects of brain damage

Even in the most favourable situation—that of a mild hæmorrhage in a fit young man—the mortality is 16% in the first eight weeks Of these deaths half should be preventable as they are due to recurrence or to slow deterioration The angiographic demonstration of lesions in less than 50% of cases is disappointing, but recent advances in technique may make a higher rate possible

If early surgery is to be contemplated, early transfer to a specialist centre is imperative Henson (1957) thinks that after the first three or four days there is no undue risk in transporting these patients Our findings do not contradict this view In particular, transport by air, involving two road journeys of up to 50 miles, does not appear hazardous The use of helicopters will make transport by air easier and quicker, and we suggest that this method will be safer for anything more than a short road journey

Summary

The natural history of 103 cases of spontaneous subarachnoid hæmorrhage in Army patients in the years 1950–56 is described

The incidence and mortality rose steadily with age Death was commoner in the first five days than later Recurrent bleeding occurred at a steady rate after the

first few days Recurrences carried a higher mortality than the first hæmorrhage

When the cases were classified clinically in terms of the severity of the initial hæmorrhage, the death-rate was found to be significantly greater among those who were comatose or completely inaccessible, or who had a complete hemiplegia The severity and duration of the disturbance of consciousness was the most reliable prognostic sign

To prevent recurrences, surgery, and therefore angiography, should be undertaken before the end of the second week Unfortunately angiograms showed the probable source of bleeding in less than half of those so investigated Transporting the patients in the acute stage did not aggravate their condition

We should like to thank Dr Honor Smith, Mr W S Lewin, Dr C W M Whitty, and Dr R G Willison for advice and criticism and the statistical division of the Army Medical Directorate for their invaluable help with the case-records

THE rising clinical demand for the fibrinogen-containing fraction of human plasma would be difficult to meet entirely with material prepared from freshly drawn blood On the other hand, relatively large quantities are recoverable from the plasma of stored blood, rejected for transfusion when the expiry date of the red cells has been passed The physical properties of the fibrinogen fraction from such blood differ slightly from those of freshly collected blood, and we have therefore observed the survival of the former fraction in the circulation of a young woman with afibrinogenæmia

Material and Methods

The Patient

In this case, previously described in detail (Pinniger and Prunty 1946, Hardisty and Pinniger 1956) the hæmostatic mechanism is normal except that the plasma forms no clot whatever, although a small, flocculent precipitate (corresponding on different occasions to 30–100 mg protein per 100 ml.) has repeatedly been observed to form after incubating recalcified citrated or oxalated plasma for an hour or more In one test the nitrogen content of this precipitate indicated that less than one third of its weight was attributable to protein The patient's platelet count runs at about 600,000 per c.mm blood (normal 150,000–350,000 per c mm blood)

Preparation of Fibrinogen from Plasma of "Time-expired" Blood

The method of Kekwick, Mackay, and Record (Kekwick and Mackay 1954) was adapted for plasma from "time-expired" blood (i e, 21 days or more old) intended also for γ-globulin fractionation The fibrinogen fraction settles less readily from old plasma by the original method, and contains a high proportion of insoluble matter

For the preparation, all reagents and vessels are sterilised A pool of 60 litres of sterile plasma is prepared from 30–40 "ten-donor" pools selected visually for low fat content, diluted with an equal volume of water and cooled to 0°C To it are slowly added 13 2 litres of diethyl ether, keeping the temperature between 0°C and −1°C and stirring until the ether has completely dissolved The mixture stands overnight at 0°C On the following day the clear supernatant is removed and the sludge containing the precipitated fibrinogen is centrifuged at 0°C The precipitate obtained is suspended in 12 litres of a solution containing 80 ml per litre of ether dissolved in 0 15*M* sodium-chloride, 0 0125*M* trisodium-citrate solution, centrifuged again, and the supernatant discarded The precipitate is re-dissolved in 6 litres of 0 3*M* sodium-chloride, 0 0125*M* trisodium-citrate solution Warming in a water bath at 37°C accelerates dissolving Fine particulate matter is removed by filtration in three stages through (1) 'Hyflo-Supercel' 300 ml loose powder per litre solution on a Ford CCNA pad (cellulose 70 sq cm per litre solution), (2) Ford FCB pad (asbestos and cellulose 70 sq cm per litre solution), (3) Carlson EK pad (asbestos and cellulose 140 sq cm. per litre solution)

The final solution is bottled, spun-frozen without delay, and dried This fibrinogen solution contains between 1 5 and 2 g protein per 100 ml, of which 60–70% is clottable. The diagram obtained by moving-boundary electrophoresis very closely resembles that of the fibrinogen fraction from fresh plasma, suggesting that the lower clottability of this preparation is not attributable to any gross change in the molecular structure or to the inclusion of proteins of other mobilities in the fraction.

After incubation at 37°C for 16–24 hours, a sterile solution 0 2 g per 100 ml in citrate saline does not clot on addition of thrombin, indicating the presence of plasmin Fibrinogen prepared from fresh undiluted plasma by the method of Kekwick, Mackay, and Record remains clottable for as long as 3 weeks under similar conditions When diluted with an equal volume of water, however, both old and fresh plasma have a short fibrinogen "life" on incubation The dilution of old plasma is necessary to induce more complete sedimentation of the fibrinogen precipitate It will be pointed out below that this apparent disadvantage of the "time-expired" material does not impair its clinical usefulness

For clinical use the product is freeze-dried in 3–4 g quantities in blood-transfusion bottles and the contents are retrospectively estimated from the nitrogen value of a representative clot. The statements given below of the quantities administered clinically are derived from these determinations

Administration of Fibrinogen Solution

The patient received two intravenous infusions, separated by an interval of 11 months

At the first (batches 105, 107, 110) she was given 13 8 g dissolved in 450 ml water immediately before a dental extraction Postoperative hæmostasis was achieved within a few hours, as in a normal person, by contrast with the oozing of some days' duration which previously followed tooth extractions in this patient when blood or a blood derivative had not been given

At the second infusion (batches 114, 115), the patient received 17 6 g in 460 ml water a week before the expected date of a menstrual period, because over the previous four months, immediately following her marriage, menorrhagia had been troublesome The subsequent period occurred a few days later than expected and was very light The plasma-fibrinogen concentration lay between 0 04 and 0 06 g per 100 ml during the menstrual period Subsequent menstrual periods have not been unduly heavy

Estimation of Fibrinogen Concentration in Plasma

After the first infusion, plasma samples were estimated by one or more of three methods

1 Oxalated plasma was recalcified and allowed to form a clot which was removed after 1–18 hours, and fibrin was determined as N by the micro-Kjeldahl technique

2 Citrated plasma was recalcified and allowed to form a clot which was removed after 10–15 minutes and the fibrin determined gravimetrically (Ingram 1952) The appearances of the clot obtained in this method were those of purified fibrinogen rather than of normal plasma Experiments in vitro confirmed that, when time-expired fibrinogen was added to the patient's plasma, fibrin could be recovered as fully as from saline solution

3 Serial dilutions of citrated plasma were incubated with coagulase-positive *Staphylococcus aureus* and the highest dilution in which clumping occurred was noted (Duthie 1954) The method was calibrated by parallel determinations on a plasma whose fibrinogen concentration had been measured by method 2

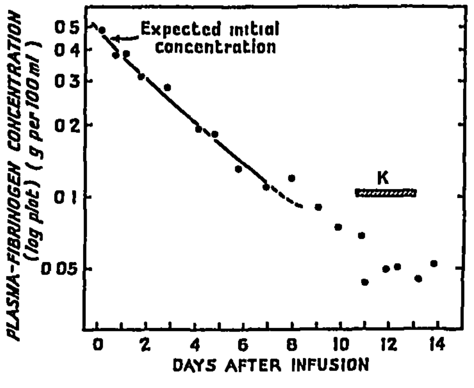
After the second infusion all samples were estimated by method 2

Results

Since, in this patient, previous transfusions had seriously disorganised the superficial arm veins, only rather small samples of blood could be obtained, and some were lost through clotting in the syringe For the same reason, it was not thought practicable to estimate her blood-volume directly, so a tentative figure for the plasma-volume was derived from the body-weight and the venous hæmatocrit

First infusion —By the three methods of determination, five samples over 12 days yielded ten estimates There was no evidence of systematic differences between the methods of estimation, and fibrinogen concentration appeared to regress exponentially against time The pooled results from the three methods yielded a rate (with standard error) for the disappearance of the fibrinogen from the patient's circulating plasma of 14.3 (±1.9) % per day From the regression curve, the fibrinogen concentration at time $t=0$ was 0.31 (±0.01) g per 100 ml plasma, which was only some 57% of the expected concentration which had been calculated from the supposed plasma-volume, but was very near the observed plasma concentration—0.28 g per 100 ml —15 minutes after the end of the infusion This was regarded as a preliminary experiment, mainly confirming the comparability of the three methods of estimation

Second infusion —Eighteen samples were obtained over 14 days and estimated by method 2 (see figure) A regression empirically fitted to the results in the form $y=\alpha+\beta\rho^t$ (where y is the fibrinogen concentration at time t, α the asymptote, $(\alpha+\beta)$ the fibrinogen concentration at zero time, taken as 10 minutes after the start of the infusion, ρ the proportion of the fibrinogen remaining in the plasma after unit time, and t the time in days) indicated a plasma concentration 2 hours after the start of the infusion of 0.47 (±0.01) g per 100 ml This agrees well with the observed value of 0.48 g per 100 ml at that time and with the expected concentration of 0.43 g per 100 ml, again calculated from the supposed plasma-volume



Plasma-fibrinogen concentration following infusion of fibrinogen in afibrinogenæmic subject (second infusion)

The fitted regression has been drawn in as far as the point where experimental error introduces considerable uncertainty Random scatter is exaggerated at low values by the log plot, but the departure from linearity when log fibrinogen concentration is plotted against time is significant The line below the letter K indicates the duration of a menstrual period Menstruation does not appear to have affected the rate of disappearance of fibrinogen from the circulation

Discussion

Two explanations are possible for the curvilinear relation between log fibrinogen concentration and time, seen in the figure Either the curve might be logarithmic but fall towards the asymptote of a low concentration always present, as in the fitted equation, or it might be the resultant of a superimposed series of movements of fibrinogen between the plasma and various extracirculatory "pools" These explanations are not of course mutually exclusive, although the first seems unlikely because previous observations have failed to demonstrate fibrinogen in this patient's blood except after infusions, nor can the flocculent precipitate previously referred to have contributed to the "asymptotic" low concentration, because it would have taken longer to appear than the time allowed for harvesting the fibrin in this experiment If the second explanation is accepted, the early, rapidly falling portion of the curve could be attributed to the initial stages of equilibration with extravascular fluid, when movement outwards from the plasma is rapid, and the later portion would principally reflect metabolic removal, at a rate masked in the earlier stages It is the slope of this later portion from which the rate of turnover has generally been derived, although of course a rate calculated directly from this slope might include a component representing back-diffusion from an extravascular pool The rate so derived from the tail of the regression of our second experiment is approximately 15% per day the line so fitted, when extrapolated back to zero time, cuts the ordinate at 0.33 g per 100 ml, which represents some two-thirds of the dose injected The separation of these complex effects requires more work, and the problem is being further studied

Meanwhile two points of interest emerge

First, it is curious that our preliminary experiment did not detect the early phase of rapid removal from the bloodstream, although otherwise our results are very similar to those obtained from a comparable infusion given to an afibrinogenæmic boy by Gitlin and Borges (1953) rapid loss of about half the injected fibrinogen was clearly demonstrated during the first 2 days It is hardly conceivable that 5.9 g (43% of 13.8 g), representing a clearance of 1.9 litres of plasma (9/20 of the assumed plasma-volume) can have been sequestered at the tooth socket in the achievement of hæmostasis (although Fitzgerald and Jackson [1956] obtained the astonishing figure of 63 g of fibrin from a retroplacental clot) It also seems unlikely that our findings could be explained by temporary fibrinogenolytic activity, happening to destroy 43% of what was administered, since one would expect to see evidence of equilibration after a short-lived fibrinogenolysis had passed off

On the other hand, in our second infusion, the initial equilibration seems to have occupied at least 4 days, in as much as after this point the observations can be fitted to a straight line on the log plot Perhaps there is great variability in the duration of the early phase of the curve in such subjects, and possibly in our first infusion this phase was already completed by the time of our first blood sample 15 minutes after the completion of the infusion

ESTIMATES OF RATES OF UTILISATION OF FIBRINOGEN IN MAN

Source	Subject(s)	Technique	Mean rate of disappearance of specific activity or material (% per diem)
Madden and Gould (1952)	Normal	Test subjects fed ^{35}S	12
Volwiler et al (1955)	„	Donor subjects fed ^{35}S	17
Christensen (1958)	„	^{131}I-labelled	15
Gitlin and Borges (1953)	Afibrinogenæmic	(1) Normal fibrinogen infused (2) Ultraviolet-irradiated fibrinogen infused	16 20
Frick and McQuarrie (1954)	„	Fraction I infused	24
Present case	„	" Time-expired " fibrinogen infused	(1) 14 (2) *ca* 15

In normal subjects the values were derived from measurements of radioactivity, whereas in the afibrinogenæmic subjects fibrinogen was assayed by chemical or immunological methods or with coagulase. The cited rates are obtained from the slow, late exponential portions of the published curves, after the initial, rapid equilibration phase was completed The mean of all the quoted values is about 17% per day, and the mean of the three rates derived from normal subjects is about 15% per day For purposes of numerical comparison with other work in which the conception of $^1/_2$-survival time has been employed, these mean values may be expressed as $^1/_2$-survival times of about 3 8 and 4 3 days respectively

The *second point* is the survival of our material in the circulation of this patient The accompanying table gives a series of values derived, as explained above, from the later, slow portion of the curve, obtained from published studies of the turnover of fibrinogen in normal and afibrinogenæmic subjects, it is apparent that our values are near their mean (17% per day) This suggests that fibrinogen prepared from time-expired blood is not destroyed more rapidly in the body than material prepared from fresh blood and may therefore be accepted as an effective substitute for it It thus seems reasonable to suppose that the plasmin contaminant of the fibrinogen preparation, demonstrated in vitro, is inactivated by the antiplasmin in the recipient's plasma

In this report we have not employed the conventional terminology of half-survival time, because we feel that the term should be reserved for strictly one-component, first-order changes, such as the decay of radioactivity Processes which are really more complex, but which are found to approximate to an exponential for a given period of observation, cannot logically be considered in terms which imply a steady logarithmic change over an indefinite time We have therefore expressed rates of change as percentages removed from the circulation per day during the periods in which observations were being made

Summary

A method of preparing fibrinogen from the plasma of " time-expired " blood is described

This fibrinogen was twice transfused into a young woman with afibrinogenæmia On one occasion a tooth was extracted and normal hæmostasis was achieved As has been reported with other preparations, about a third to half of the injected dose was rapidly lost from the circulation, but the remainder disappeared more slowly at about 15% per day

This value, which compares well with those obtained in other ways, probably represents the normal rate of turnover of this protein Fibrinogen prepared from " time-expired " blood thus seems likely to be of similar clinical value to that obtained from fresh blood

Our thanks are due to Dr C A Foster for his help with the infusions and with the venepunctures, to Dr N P L Wildy for performing the coagulase tests, to Dr G Bartsch, of the Medical Research Council's Statistical Research Unit, for the statistical analysis of the second regression, and to Dr W d'A Maycock for valuable discussion and criticism

A J H TOMLINSON
M B Cantab

DIRECTOR, PUBLIC HEALTH LABORATORY, COUNTY HALL, LONDON

EXACERBATIONS of chronic bronchitis are among the most common conditions presenting for treatment in general practice in Britain (Pemberton 1949, Fry 1954, Horder and Horder 1954, Logan and Cushion 1958) Until recently treatment was ineffective, but now, for the patient with severe chronic bronchitis, the value of long-term antibiotics in shortening attacks (May and Oswald 1956, Moyes and Kershaw 1957, Buchanan et al 1958) and in preventing them (Edwards et al 1957, Buchanan et al 1958, Edwards and Fear 1958) is reasonably well established The evidence in favour of treating exacerbations with short courses of antibiotics is less conclusive (Elmes et al 1957)

Chronic bronchitis is gradual in its onset In the early stages the patient usually enjoys good health punctuated by " chesty colds " Later on repeated attacks lead to a permanent loss of respiratory function which may remain moderate or may proceed, with exacerbations, to respiratory failure and death In general practice, patients may come for treatment at any stage of this process, and in the cases where permanent respiratory symptoms are moderate or slight the precise indications for antibiotic treatment are far from clear

The Present Investigation

The investigation reported here was a double-blind controlled trial of antibiotic treatment of exacerbations of chronic bronchitis which were mild or only moderately severe In planning the trial, and during the preliminary pilot studies, it was apparent that in severely ill patients the use of control treatments would be ethically indefensible It was not, however, possible to devise a method of assessing severity which could be uniformly applied by all the doctors participating Accordingly the practitioner was asked to classify his cases, on his own judgment, as

A. Antibiotic necessary
B Intermediate
C Antibiotic unnecessary

Patients in group A were treated as the doctor thought

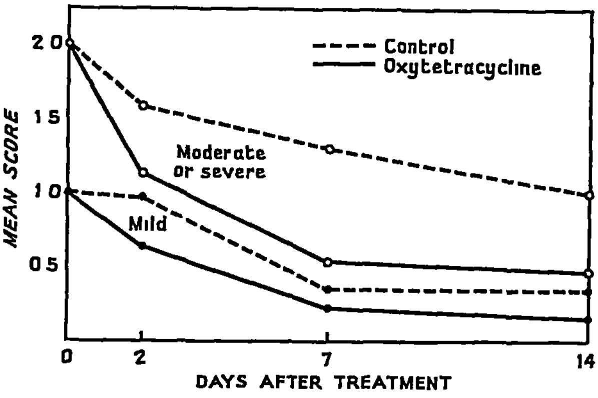
fit, the controlled trial being confined to groups B and C In this way no patient entered the trial if his doctor felt that antibiotic treatment was imperative

The antibiotic selected for trial was oxytetracycline, a drug active against the common pathogens in chronic bronchitis (Flint 1954, Gabrielson et al 1954, Helm et al 1954) and, at least under general-practice conditions, free from serious side-effects Chloramphenicol, while perhaps more effective, is unsuitable for use in a frequently recurring condition, because it may damage bone-marrow A mixture of penicillin and streptomycin gives good results but has to be given intramuscularly and is therefore unsuitable for a blind controlled trial Moreover it carries a small risk of VIII-nerve damage, especially in the elderly

Methods

For the purposes of this investigation chronic bronchitis was defined as " a condition in which there is persistent or recurrent cough with diffuse physical signs in the chest, in which X-ray has excluded other disease " A patient was held to be suffering from an exacerbation when there had been " a sudden worsening (during the past week) characterised by one or more of the following symptoms increased cough, increased volume of sputum, increased purulence of sputum, increased breathlessness or fever " The " baseline " severity of each patient's bronchitis was indicated by his exercise tolerance during the previous summer, according to the following grades



Response of treated and control groups

Grade 2—Able to walk with normal people of own age on level, but unable to keep up on hills or on hurrying because of breathlessness Able to do all housework, but breathless on digging for more than short periods and carrying loads (e g , coal) upstairs

Grade 3—Unable to keep up with fit people walking on the level Able to walk at least one mile flat and to climb a flight of twelve stairs without distress and to perform light household duties

Grade 4—Unable to walk more than 300 yards without pause for breath Able to do sedentary work and the lightest household jobs

Grade 5—Breathless on walking a few yards or on undressing

The severity of the exacerbation was assessed at first presentation, and after 48 hours, 7 days, and 14 days, on a four-point scale, as follows 0, patient's baseline, 1, mild attack, 2, moderate attack, 3, severe attack More objective criteria of severity proved impracticable In some cases intermediate scores (0 5, 1 5, &c) were employed

In addition to recording the severity of the patient's bronchitis, and of the exacerbation, a record was also made of the patient's age and sex and of the presence or absence of the following features of the exacerbation increased cough, increased sputum, increased purulence of sputum, increased dyspnœa, and fever Sputum was sent for culture after the first consultation and after the completion of treatment—all bacteriology being carried out at the same laboratory

TABLE I—CHARACTERISTICS OF THE TREATED AND CONTROL GROUPS

—	Oxytetracycline	Control
Total cases	26	27
Classification at presentation		
B	15	16
C	11	11
Age		
Less than 45	4	7

Organisms present in sputum at onset		
Pneumococcus	6	6
Influenza bacillus	6	6
Streptococcus	2	7
Other	2	1
Nil	10	7

As explained above, a patient presenting with an exacerbation of bronchitis was initially assigned by the doctor to one of three categories (A) antibiotic necessary, (B) intermediate, or (C) antibiotic unnecessary Patients in category A were not included in the trial but record cards were completed for them Patients in category B and C were provided with a course of capsules, containing either oxytetracycline (given in the dosage 250 mg q i d for 5 days) or lactose The practitioners each had a series of numbered bottles containing either oxytetracycline or lactose, arranged in random order, the key to the numbers being in the possession of another member of the group All the patients were given oral vitamin B and expectorants, antispasmodics, and other treatment as indicated

Results

Fifty-eight patients were placed in categories B and C and entered the trial The records of two of these patients were inadequate, and in three other cases treatment was discontinued because of possible toxic effects from the tablets (two were on oxytetracycline and one on control tablets) In addition, records were kept of eleven cases in category A

TABLE II—PROGRESS OF TREATED AND CONTROL PATIENTS CLASSIFIED ACCORDING TO THE SEVERITY OF THE EXACERBATIONS

—	Total	Failures	Mean severity score on day			
			1	2	7	14
Mild attack						
Oxytetracycline	11	0	1 00	0 64	0 23	0 14
Control	13	1	0 96	0 96	0 32	0 31
Significance			N S	N S	N.S	N S
Moderate/severe attack						
Oxytetracycline	15	0	2 03	1 13	0 53	0 47
Control	14	4	2 04	1 57	1 36	1 00
Significance			N S	5%	5%	N S

N S , not significant

Table I shows that the treated and control groups were very similar in composition For the purpose of analysis the patients were further divided according to the severity at onset, cases scoring 1 being regarded as mild and those over 1 as moderate-to-severe At assessments after the first, the withdrawal of the patient from the trial because of poor progress was recorded as a failure and scored 4 points

The response of the treated and control groups is recorded in table II and in the figure In both the mild and the moderate-to-severe groups the treated patients did better than the controls In the mild cases this difference was not significant, but in the moderate-to-severe group it was significant at 2 and 7 days * By 2 days fourteen treated patients were improving compared with only seven control patients, one control had been withdrawn from the trial and put on other treatment After 1 week, seven treated patients had returned to their base-line condition whereas only 1 control had done so and two further control cases had been withdrawn By 14 days the advantage of the treated patients ceased to be significant, but a fourth control patient had required alternative treatment

TABLE III—CHARACTERISTICS OF PATIENTS IN CATEGORIES A, B, AND C

—	A	B	C
Total number	11	31	22
Age

,, 3	3	11	3
, 4–5	4	4	2
Not known	0	1	
Symptoms of exacerbation			
Fever	8	9	3
More purulence	11	20	12
Severity of exacerbation at onset			
1	3	8	16
2	3	22	5
3	5	1	1

Further analysis shows that the advantage of the treated over the control patients was largely confined to the patients in category B (intermediate) In fact there is a close correlation between the initial assessment of severity and the classification into categories B and C The advantage of treated patients over controls applied irrespective of whether any organism was cultured or not

The eleven patients in group A, who remained outside the trial, were treated with various antibiotics Two of them died

Discussion

Our results show that, even where antibiotic treatment is not considered essential, a patient with an exacerbation of bronchitis may derive measurable benefit from it—at any rate if the attack is more than mild

The criteria on which patients were assigned to category A, B, or C, and on which they were graded for severity, are likely to have varied between participating doctors Table III compares the features of the patients in groups A B, and C, and suggests that the decision to give antibiotics was based on the patient's greater age, on the severity of the bronchitis and of the exacerbation, and on the presence of fever and purulent sputum

Summary

A double-blind controlled trial of oxytetracycline in mild or moderately severe exacerbations of chronic bronchitis is described

The trial was carried out by a group of general practitioners on a total of fifty-eight patients

Treated patients recovered sooner and deteriorated less often than the controls This advantage is statistically significant for patients with moderately severe attacks but not for those with mild attacks

We are grateful to Messrs Pfizer for a supply of oxytetracycline ('Terramycin') and dummy capsules, and for the advice of Dr W Williams We are also indebted to Dr C M Fletcher and Dr N C Oswald for their helpful advice.

PHYSICIAN TO THE UNITED BRISTOL HOSPITALS

CORTISONE and corticotrophin are known to be valuable in the treatment of status asthmaticus, but opinions differ as to their use in chronic asthma Good results have been reported with prolonged treatment (Lowell et al 1953, Savidge and Brocklebank 1954a, Davies and Williams 1955, Morrow Brown 1958) In contrast, the Medical Research Council (1956) found that the initial improvement in patients having cortisone, as compared with control patients, was not maintained At the end of 6 months there was no significant difference between their two groups Our findings are at such variance with those of the Medical Research Council that we wish to present the results of our own experience, for we consider these drugs to be of real value in severe chronic asthma

The Trial

A group of fifty patients were treated with steroids for periods of 3 months to $5^1/_2$ years (mean duration 2 7 years) There were thirty-three women and seventeen men, aged 23–66 (mean 47 2 years) All had severe chronic asthma, resistant to conventional treatments, and responding initially to steroids Most had been unable to work or do their household duties for many months, and frequent hospital admissions had been necessary The mean duration of asthma was 10 3 years

Cortisone was given by mouth to thirty patients, most of whom needed 50–75 mg daily Corticotrophin proved more effective in four cases, and sixteen of the later cases were treated with prednisone Response to treatment was assessed by the frequency of paroxysmal dyspnœa, the capacity for exercise and work, and the degree of bronchospasm

---

* Significance is calculated by the method of Armitage (1955) from the actual score distributions This takes into account the non-metrical nature of the scores

Results

Good results were obtained in thirty-nine of the fifty patients, and there was moderate improvement in five others The results were poor in two women and one man with infective asthma associated with persistent purulent sputum, and three patients died during treatment Twenty-one patients, previously unable to work, resumed their paid jobs or household duties

Illustrative Case-reports

CASE 1 —A woman, aged 33, had had severe asthma for 14 years and had been admitted to hospital twelve times during this period Severe bronchospasm persisted for half the year She felt that her family was neglected She improved within 2 days of starting treatment with cortisone, and for the past $5^1/_2$ years, while taking 25–37 5 mg daily, she has remained almost free of asthma She had a severe relapse 4 weeks after cortisone was stopped in a double-blind trial

CASE 2 —A man, aged 64, had been subject to winter bronchitis with purulent sputum for 30 years During the past 6 years increasingly severe paroxysmal dyspnœa had developed He had been in hospital with asthma three times in the past year, and he was afraid to work Cortisone was started in November, 1956 His condition improved rapidly, and he has since had only moderate bronchospasm for a few weeks each winter in association with infection He has taken cortisone 25–50 mg daily He relapsed 2 weeks after cortisone was stopped in a double-blind trial

CASE 3 —A woman, aged 60, who had had asthma for 21 years, had been forced to give up her light assembly work 6 years previously She had been in hospital continuously for 2 years, having frequent injections of adrenaline and aminophylline In the past $4^1/_2$ years, while taking cortisone 50–75 mg daily, she has had only mild attacks of asthma, and she can now do all her own housework She relapses when given control tablets

Side-effects

Rapid weight gain, due both to improved appetite and to fluid retention, made it necessary to restrict many patients to a low-salt reducing diet Cortisone had to be stopped in two patients because of severe depression Hirsuties and a moon-face developed in three patients

Deaths

Three patients died during treatment

CASE 4 —A woman with asthma, aged 54, was treated for $3^1/_2$ years with cortisone or corticotrophin, and she showed moderate improvement While in hospital with a relapse of asthma associated with bronchitis, she died of cerebral hæmorrhage At no time was her blood-pressure raised The suprarenal glands were macroscopically normal at necropsy

CASE 5 —A woman, aged 41, had asthma which was treated with cortisone 75 mg daily, with good result She was then admitted to hospital with bronchitis, and cortisone was stopped 7 days later severe asthma developed Cortisone 100 mg daily was restarted on the 11th day, but she did not respond, and she died in status asthmaticus on the 19th day Necropsy showed macroscopically normal suprarenal glands

CASE 6 —A man, aged 34, had severe congenital kyphoscoliosis with advanced emphysema and persistent bronchospasm. He had been unable to work for 3 years In 1955 he was in hospital with severe congestive cardiac failure, and he responded very slowly to treatment After discharge he remained cyanosed and dyspnœic on slight exertion, being able to walk slowly only about 200 yards Treatment with prednisone was started in September, 1956 Within 2 days there was much improvement and the bronchospasm disappeared The patient was able to resume clerical work and to dig his garden After 4 months' treatment with cortisone he died at home of acute bronchitis Necropsy was not performed.

Death in case 4 was unlikely to be related to treatment, although the cause of her cerebral hæmorrhage was obscure In case 5 it was most unfortunate that cortisone was stopped on admission and restarted in inadequate dosage The third patient (case 6) was an ill man before treatment, and his terminal bronchitis cannot reasonably be ascribed to prednisone

Control Periods

In fourteen cases which were satisfactorily controlled on cortisone, inert tablets were substituted without the patients' knowledge Of these, eight showed a definite relapse within a period of 2 months, two being admitted to hospital in status asthmaticus The condition of five other patients deteriorated more gradually and one remained unchanged Shortly after stopping treatment twelve other patients relapsed These results encouraged us to undertake a double-blind trial, for it seemed important to provide more objective evidence of prolonged benefit from cortisone, even at the expense of distressing relapses

Double-blind Trial

Eleven patients took part in the double-blind trial A twelfth patient moved away from the district during the trial period All were severe chronic asthmatics, who appeared to require a maintenance dose of cortisone. There were eight women and three men, with a mean age of 54 years They were seen at 2–4-week intervals, when their symptoms and working capacity were noted The degree of audible bronchospasm was assessed and the 1-second forced expiratory volume (F E V$_1$) was recorded (Thomson and Hugh-Jones 1958)

During an initial observation period of 3–5 months (mean 18 6 weeks), the patients continued to have cortisone in the smallest dose which controlled their symptoms This varied from 25 to 75 mg daily During the next 3 months half continued with cortisone, and the others took identical inert tablets The change from cortisone to control tablets was gradual in order to avoid sudden withdrawal

The standard 25 mg cortisone tablets were replaced by tablets containing 17 mg cortisone for the first control week, and 8 mg for the second control week Inert tablets were continued thereafter Neither patient nor doctor knew whether cortisone or inert tablets were being dispensed

If a patient relapsed, known cortisone was restarted and continued until the end of the 3-month period The general practitioners knew of the trial and were warned to give cortisone if necessary At the end of 3 months the patients changed from cortisone to inert tablets, and vice versa, for a further 3-month period

Results

During the initial observation period there were minor relapses only But during the period on unknown inert tablets, nine patients had moderate or severe recurrences of asthma, which kept them in bed and prevented work Several of these relapses were of alarming severity

CASE 1 —(See above) This patient developed troublesome asthma on the first day of a family holiday after 4 weeks of the control period For a fortnight she was unable to leave the holiday cottage, apart from short drives when she was confined to the car, and she could do no housework. Her husband was most unsympathetic, and the couple were at loggerheads for weeks She improved rapidly when known cortisone was again started by her doctor

Two patients relapsed during the first fortnight, while the dose of cortisone was being reduced Three patients relapsed at the end of the first fortnight, and the other four 3–5 weeks after starting the control period Improvement was usually rapid after cortisone was resumed, though several patients were persistently more wheezy than usual for up to a month One patient relapsed after 5 weeks of the unknown cortisone period and improved 3 days after restarting known cortisone Another patient remained well throughout both parts of the trial

The FEV$_1$ readings were not helpful as a means of comparing the periods on cortisone and control tablets Because patients often relapsed early in the 3-month periods cortisone was usually restarted by the general practitioner, and spirometry was not done at the time of relapse In four patients, however, where comparable measurements were made in the two periods, the mean FEV$_1$ during the cortisone period was 490 ml and during the control period 380 ml It is interesting that the mean FEV$_1$ of the patient who relapsed while taking unknown cortisone was 480 ml, compared with 360 ml during the control period in the other half of the trial

Thus nine patients relapsed while taking unknown inert tablets, and one while taking unknown cortisone The probability that this distribution of relapses was due to chance is 1 in 1000

Discussion

Most of these severely disabled asthmatics showed considerable improvement with prolonged steroid treatment, and other workers have reported similar good results Our double-blind trial shows more objectively that prolonged control of severe asthma is usually achieved with cortisone It can be argued that prolonged treatment with cortisone merely suppresses the normal adrenal output Relapse on withdrawing cortisone would then result from adrenal suppression We tried to avoid such an acute withdrawal effect by gradual reduction of cortisone dosage

There are features of the Medical Research Council trial which we venture to criticise and which may explain why prolonged benefit from cortisone was not demonstrated

To consider first withdrawals from the trial groups, if we assume that most defaulters failed to continue treatment because of failure to benefit, we find that ten left the control group by reason of continuing asthma (five in status asthmaticus and four defaulters), while only four left the cortisone group (two in status asthmaticus and two defaulters) Thus it seems that the control group was gradually shorn of its severe asthmatics as the trial proceeded, and that cortisone was at a disadvantage in a group with more severe and persistent asthma Cortisone was said to be ineffective after the first 8 weeks, but only two patients having cortisone (one in status asthmaticus and one defaulter) left the trial after 8 weeks by reason of asthma, while five (three in status asthmaticus and two defaulters) left the control group after 8 weeks

The control patients had a higher mean " dose " of placebo (3 54 tablets per day) at the 3-month midpoint of the trial than the patients having cortisone (2 86 tablets per day) This larger number of tablets suggests that asthma was more troublesome in the control group The cortisone group did, in fact, show some advantage at the end of the trial in exercise tolerance and working ability, and the clinicians taking part thought that twenty-three of the forty-nine patients improved during the trial whereas only twelve of the forty-seven control patients improved Four of the five hospitals concerned were still using prolonged cortisone treatment for approximately two-thirds of both the control and the cortisone groups when they submitted their reports 6–22 months after the trial Our trial, of course, is not strictly comparable to the Medical Research Council trial, in that they compared prolonged treatment with cortisone with prolonged treatment with a placebo, whereas we stopped cortisone treatment even in patients who were doing well on it

It is important that an adequate amount of cortisone be given, for severe asthma returns in many patients if the dose falls below a critical level We encourage patients to increase their dose if necessary, especially if a chest infection develops, provided always that they take the smallest effective amount Short antibiotic courses are arranged for patients liable to recurrent chest infections In time, many patients are able to reduce their dose of cortisone Six patients have now stopped treatment altogether after long courses of cortisone, and seven require only intermittent treatment The need for continued treatment should be reassessed periodically by the cautious use of control tablets, for patients are very liable to become dependent on cortisone

The risks of prolonged treatment with steroids are well known, and a number of deaths have been reported during treatment (Savidge and Brocklebank 1954b), which may have resulted from adrenal atrophy (Stoner and Whiteley 1954) To prevent such deaths cortisone must be withdrawn gradually in patients treated for long periods, and really adequate doses must be given to cover the stress of operations or infections Patients should carry a card with details of their treatment to warn doctors dealing with such emergencies The weight and blood-pressure should be recorded regularly, the urine tested for sugar, and a chest radiograph taken every 6 months

We conclude that prolonged treatment with steroids is justified and valuable in a small carefully selected group of patients who are severely disabled by chronic or frequently recurring asthma

Summary

Fifty patients with severe chronic asthma were treated with cortisone, prednisone, or corticotrophin for a mean period of 2 7 years The results were good in thirty-nine (78%) Apart from two cases of depression, side-effects were slight

In a double-blind trial with eleven patients, nine relapsed during the control period, and one during the cortisone period The probability that this was due to chance is 1 in 1000

We are very grateful to Dr Richard Doll for the design of the double-blind trial, and for assistance in the interpretation of its results, and to Dr Horace Joules for help and advice The control tablets were kindly supplied by Dr H M Walker and Mr J C H Hanson of Glaxo Laboratories, Ltd, and we appreciate the cooperation of Miss K Knight in dispensing them

SKIN CHANGES IN HYPOCALCÆMIA

C E DENT

M GARRETTS
M B Lond , M R C P
MEMBER OF DEPARTMENT OF DERMATOLOGY

UNIVERSITY COLLEGE HOSPITAL, LONDON, W C 1

THE association of hair and nail anomalies with hypocalcæmia is well known, and the occurrence of cataracts also well recorded (Albright and Reifenstein 1948)

Simpson (1954) has classified the dermatological manifestations of hypocalcæmia due to hypoparathyroidism and steatorrhœa as follows

(1) Abnormalities of nail and hair growth with latent or manifest tetany of acute onset

(2) Skin, nail, and hair changes after prolonged hypocalcæmia

(3) Secondary infection of skin and nail, often with monilia

While the above trophic ectodermal lesions of hypoparathyroidism have been well recorded, only one reported case of exfoliative dermatitis in this disease could be found (Lachmann 1941) until the recent addition of one further case by Harell-Steinberg et al (1957) This second case had generalised exfoliative dermatitis with sparse hair, leucocytosis, eosinophilia, and low serum-proteins with reversal of the albumin-globulin ratio The skin improved with the administration of irradiated ergosterol These two cases are extremely important since the serum-calcium level is not studied routinely in eczematous patients

In the present paper we describe four further cases of hypocalcæmia These differed in ætiology since one patient had permanent hypoparathyroidism following the removal of a non-toxic thyroid adenoma, one had severe but temporary hypoparathyroidism following the removal of a large parathyroid tumour, and two had steatorrhœa—idiopathic in one and probably cœliac in the other These cases, and two further cases to be briefly mentioned, exhibited a dermatosis which could be related in onset and severity to the level of the serum (or plasma) calcium

Methods

Plasma (or serum) calcium was determined by the standard macro method using oxalate precipitation and titration with permanganate

Throughout this paper we use the term vitamin D to mean either vitamin D$_2$ (calciferol or ergocalciferol), vitamin D$_3$ (natural vitamin D or cholecalciferol), or dihydrotachysterol (D H T) By ' AT10 ' we mean the proprietary form of irradiated ergosterol of which 1 ml is stated to be equivalent to 1 25 mg of pure D H T Where we have used pure vitamin-D preparations the compound has been made up in our own pharmacy in peroxide-free arachis oil with antioxidant and given out in gelatin capsules of various sizes Frequent assays have confirmed the stability of our preparations We have preferred throughout to cite vitamin-D dosages on a mg basis since in the treatment of hypocalcæmia dosages of all preparations thus expressed are closely comparable 1 mg of vitamin D$_2$ and of D$_3$—40,000 I U D H T and AT10 have little antirachitic activity in the rat assay method so cannot be measured in international units

Case-records

Case 1 —A married woman, aged 63, was admitted to University College Hospital on June 4, 1951, having been referred to us by Dr D Ferriman for further investigations as a possible case of hyperparathyroidism She gave a typical history of increasing pain and muscular weakness, and investigations showed high calcium, low phosphorus, high phosphatase, and X-rays pathognomonic of osteitis fibrosa generalisata A parathyroid tumour was found and removed on July 5, 1951, by Mr W R Merrington, and she recovered well from the immediate effects of the operation A week later, however, she developed acute anxiety (without any of the other signs of tetany) which was found to be due to hypocalcæmia, her plasma-calcium being then 5 6 mg per 100 ml. These attacks were relieved by intermittent intravenous injections of calcium gluconate, but the calcium remained low in spite of this, although her bone pains and other signs were improving On July 23, 1951, she developed a generalised rash with severe itching and swelling, especially of her face

On examination she had generalised eczema particularly severe on the face, eyelids, trunk, and lower limbs There was swelling of the face with erythema, scaling, and vesiculation together with excoriations on the arms and thighs There was erythema with scaling of the scalp and sparseness of hair

A drug eruption was thought to be the likely diagnosis, but the only medicament which was being used was calcium gluconate by intravenous injection Intradermal skin tests with calcium gluconate were negative The skin improved a week later and then in another fortnight became much worse with generalised œdema, especially of her face, so that she could not open her eyes This rash was at first attributed to the intravenous calcium It continued, however, when the injections were stopped for a short period and it did not heal finally for about two months In retrospect the first temporary improvement (while large intravenous doses of calcium gluconate were being given) and her final spontaneous recovery coincided with rises of plasma-calcium to about 7 and to 8 mg per 100 ml respectively (see fig 1) She was followed up for several years Her serum-calcium remained normal, she had no further rash We now have reason to believe that this patient also had occult idiopathic steatorrhœa as in the patient described by Davies, Dent, and Willcox (1956) Unfortunately the opportunity to confirm this diagnosis on a further admission to hospital has not yet arisen

Case 2 —A married woman, now aged 68, was referred to the psychiatric clinic of University College Hospital by her private doctor on account of severe psychological changes Dr E Roderic-Evans, who saw her there, thought that these might have been precipitated by disturbed metabolism and referred her therefore to one of us

When seen here (Feb 27, 1952) she was found to have pronounced symptoms and signs of tetany, a rash on her hands, and hopelessness, anxiety, depression, and fear of being alone

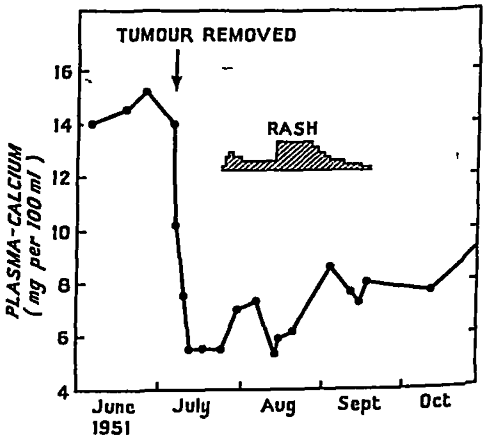

Fig 1—Case 1 relation between plasma-calcium and intensity of eruption

The rise in calcium during July 30 to Aug 6, 1951, and on Sept 3, 1951, coincided with heavy intravenous calcium gluconate therapy The final rise in calcium was probably spontaneous

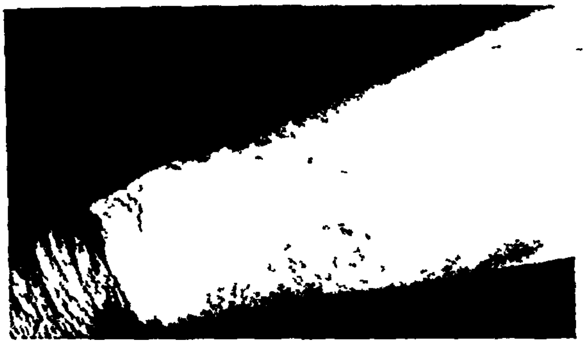

Fig 2—Case 2 eczematous papulo-vesicles on the right arm with redness and scaling

This eruption occurred on the limbs, face, and neck, whenever her serum-calcium level fell below 9 mg per 100 ml

These mental symptoms had recently been so bad that she had begun to consider taking her life.

All these troubles followed removal elsewhere of her thyroid gland in September, 1950, on account of a lump at first thought to be malignant After the operation she was told that it had not been confirmed as malignant and that four glands behind the thyroid had also been removed. From then on she has been given thyroid medication. On account of the tetany she was also given at first AT10, but as this did not appear to help, injections of ' Parathormone ' were begun. This relieved her symptoms and she left hospital well in November, 1950, still on parathormone In January, 1951, she began to have attacks of vomiting, constipation, and weakness, diagnosed at first as " gastric flu " This continued till March, when this was shown to be associated with a serum-calcium of 18 mg per 100 ml and a blood-urea of 116 mg per 100 ml The parathormone was then stopped, and she got better and remained well for about four months All the original symptoms returned, however, in October, 1951 She was then intermittently treated with AT10 and calciferol without much improvement. On Feb 2, 1952, parathormone was again given. It relieved her symptoms for a week, after which it seemed to become ineffective, and she broke down mentally and was soon referred to the psychiatric department at University College Hospital, and thence to us

She then reported that she had a rash between her fingers This had come and gone with each previous worsening and improvement of her signs of tetany, and when severe had spread over her whole hands and forearms On examination, she had gross tetany and was very disturbed mentally, feeling depressed and complaining about everything No other physical signs of disease were discovered Plasma calcium 5 9, phosphorus 6 6, mg per 100 ml Very thorough investigations were then undertaken in the metabolic ward of her response to parathormone and to oral AT10 and calciferol

We found that she was difficult to control with either form of vitamin D, but we eventually worked out a suitable dosage and later changed her drug satisfactorily to pure D H T We also confirmed the association between the rash (fig 2) and the hypocalcæmia (fig 3) From then until the time of writing (June, 1958) she has been regularly followed as an outpatient. She has shown herself to be unusually sensitive to variations in her plasma-calcium Several times during this period she has developed early signs of tetany when her plasma-calcium has fallen slightly (below 9 mg per 100 ml), and at other times she has noted signs of milk intoxication when it has risen to only slightly abnormal levels (above 11 mg per 100 ml.) Because of the difficulties in maintaining her plasma-calcium between the narrow limits, we had several opportunities to observe the effects of these changing levels These effects were twofold when the calcium was either high or low she became exceedingly depressed and mentally unstable, when it was low she also developed a rash, which always got better when the calcium was raised to normal or above normal. During this follow-up there were four further occasions (only two are shown in fig 3) on which she had the rash in association with a plasma-calcium of less than 9 mg per 100 ml. She has never had the rash when the plasma-calcium has been above 9 mg per 100 ml. When present for only a short time the hypocalcæmia was associated with only minor itching and eczema between the fingers On two occasions (fig 3) it was more severe and of longer duration and comprised more generalised eczema affecting her lower limbs, face, and neck.

The rash occurring during October and November, 1952, was of particular interest. On this occasion we did not attribute the rash to the slight lowering of her plasma-calcium, for it appeared around her neck and seemed to be related to the dyed fur collar that she was wearing When she stopped wearing the collar, the rash improved a little. She had a multicoloured jumper made of wool, which later appeared to produce an eruption on the neck, shoulders, arms, and wrists At this time she was seen in the dermatological department, when patch tests with wool fibres from the incriminated jumper were performed. These patch tests were positive During this period other garments were suspected of irritating the skin. The rash rapidly improved, however, when her plasma-calcium was raised to normal, so we presumed that the slightly low plasma-calcium (as later in 1956) was the main precipitating cause of this rash. Later, when the plasma-calcium level was restored to normal, the suspected garments could be worn again without causing irritation. Of especial note in this case was the fact that her plasma-calcium has been raised to normal on three occasions with parathormone, once perhaps as the result of a parathyroid graft and on all the other occasions with a form of vitamin D The rash improved equally well whichever treatment was given.

Case 3 —A married woman, aged 61, was complaining of an eruption on her hands and arms which had been present on and off for the past eighteen years, though she remembered having occasional skin trouble for the past forty years

When first seen by Dr P J Hare in February, 1957, she had a rash on the hands and forearms which he thought was a contact dermatitis, though there were no apparent contact factors

In July, 1957, she was admitted to St Pancras Hospital under the care of Dr J F Stokes She was then in cardiac failure, with attacks of paroxysmal supraventricular tachycardia She was noted to be of short stature and was found to have biochemical and X-ray evidence of osteomalacia We thought that she was probably an adult survivor of cœliac disease At this time, her skin disease was quite severe Trousseau's sign was positive. She had redness, scaling, and slight oozing affecting the whole of her body surface except

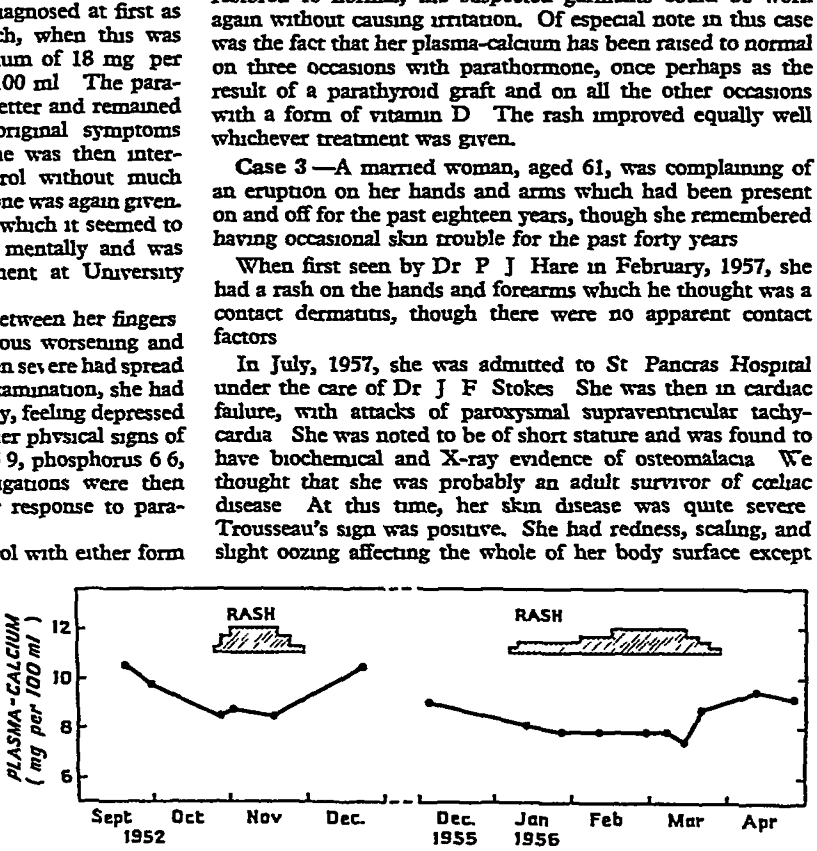

Fig 3—Case 2 relation between plasma-calcium and intensity of eruption.

The fall in calcium in 1952 occurred immediately following insertion of a homologous parathyroid tumour into the patient's thigh, other treatment having been stopped We believe it represents the slow and final death of the graft After this the patient received AT10 for some while The prolonged fall in calcium during early 1956 occurred during therapeutic trials of AT10 and pure D H.T in various doses, for which the patient had very kindly volunteered the face, which was relatively spared The nails were thickened and the soles and palms were hyperkeratotic The flexures were moistened by a serous discharge and were particularly severely affected The scalp was very scaly, giving an overall impression of seborrhœic dermatitis in an erythrodermic phase Her hair was thin and brittle

Her hæmoglobin was 64% and the mean red-cell diameter was 7 5 μ This macrocytic anæmia was thought to be an expression of her malabsorption syndrome, and her total fæcal fats were 63% (dry weight) Fat balance showed deficient absorption

She was treated with digoxin and iron, and was given pure D H T 1 mg b d by mouth A gluten-free diet was not considered practicable Cardiac failure diminished, the plasma-calcium rose, and Trousseau's sign became negative Between December, 1957, and February, 1958, she was maintained fairly well The plasma-calcium remained low—approximately 8 0 mg per 100 ml —but her skin improved considerably During January D H T was omitted owing to a misunderstanding, and her plasma-calcium fell to 7 2 mg per 100 ml and the skin became much more red, scaly, and itchy The dose of D H T was raised temporarily to 15 mg daily and then lowered to 5 mg daily, and on this dose the plasma-calcium rose from 7 2 to 7 6 mg per 100 ml over the course of four weeks (see fig 4)

She improved so much that she was allowed to go home for Easter in April, 1958 After three days at home during very cold weather, she returned having changed greatly Her rectal temperature was 86°F and she was very sleepy She died in coma on April 9, 1958

Postmortem examination showed the presence of bronchopneumonia, and there were pinpoint yellow areas surrounded by hæmorrhage in both adrenal cortices It was thought that this patient died of hypothermia

Case 4 —A man, aged 63, first attended the dermatological outpatient department in 1953 complaining of a rash which he had had on his legs for the past three months He admitted to some recent loss of weight and had suffered from indigestion The rash was worst on the legs behind the knees and on the sacrum (fig 5) The rash consisted of blue-red erythema with oozing and crusting in the groins, around the genitalia, and on the thighs, buttocks, and sacral area In these areas there was dark bluish-brown pigmentation, with thick scaling and crusting in the folds The eruption was foul-smelling and tacky, and more peripherally there were brown pigmented lichenified areas with bluish-red papules, ill defined, 3–4 mm in diameter The natal cleft was sore The rest of the body was pigmented, pale fawnish-yellow There was fœtor from the mouth, the corners of the mouth were crusted *Candida albicans* was grown from the mouth and from the groins The nails were grossly thickened, and the tongue was glazed and atrophic

He was admitted to hospital but could not stay in for long and was discharged after a month somewhat improved His rash slowly healed with pigmentation, but relapsed to its former state Grenz rays and local applications helped him to some extent

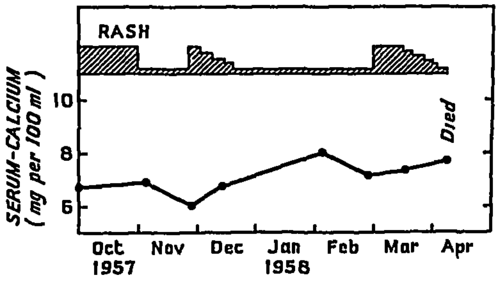

Fig 4—Case 3 relationship between serum-calcium level and intensity of eruption

The patient died before her calcium could be made quite normal and the rash completely healed

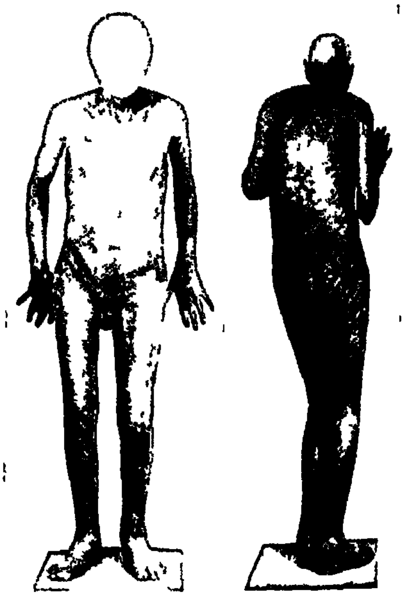

Fig 5—Case 4 redness, scaling, and vesiculation mainly on the trunk and lower limbs

There is pronounced pigmentation of the skin, especially intense in areas affected by the eczematous changes Photograph taken before steatorrhœa was diagnosed, when the serum-calcium was probably in the region of 5 mg per 100 ml

He remained fairly well during 1954, though his skin was always rough and scaly, and in 1955 he was readmitted He was found to have macrocytic anæmia, and was treated with local applications and vitamin B_{12} He was discharged improved

In 1957 he was once more admitted with generalised erythroderma, severe pigmentation, and macrocytic anæmia He was prematurely bald and had clubbed fingers Dr J Nelms (house-physician) suggested that the patient was suffering from steatorrhœa, and the fat-balance and X-ray pictures of barium meal and follow-through confirmed this view He had had chronic bronchitis on and off for ten years, but soon after admission he had an attack of stridor, tingling in the hands, and muscle cramps His serum-calcium level was found to be 5 0 mg per 100 ml and his phosphorus 1 0 mg per 100 ml Trousseau's and Chvostek's signs were positive

He was then seen by one of us (C E D) who agreed that the low serum calcium and phosphorus were due to steatorrhœa Raising his serum-calcium by means of pure calciferol 5 mg b d by mouth improved his chest condition and caused his cramps to disappear and his eczema to heal He was also given 'Diodoquin' (di-iodohydroxyquinoline) orally at first, but it was not considered to have played a part in his improvement and was later stopped

He was discharged well, and remained in fairly good health until his calciferol was stopped in May, 1957, when calciferol ('Sterogyl') 50,000 I U (1 25 mg) b d by mouth was substituted to see if this helped more He rapidly deteriorated, he became weak, and redness and scaling reappeared His serum-calcium level fell to 5 3 mg per 100 ml Treatment by mouth with pure calciferol (5 mg t d s) was reintroduced The serum-calcium level was restored to normal and the skin rapidly improved (fig 6)

He continues to be treated with vitamin B_{12} and oral calciferol (5 mg b d) and remains well

The eczema which became generalised and produced an exfoliative dermatitis in this man was peculiar in that deep pigmentation occurred Skin pigmentation is a common feature in steatorrhœa, and it is thought that it was the presence of steatorrhœa which determined the pigmentation in this patient The pigmentation which he exhibited was, however, more bizarre and deeper than is usually associated with that condition

Biopsy showed the histological features of eczema with deposits of melanin deep in the dermis as well as in and around the basal-cell layer No evidence of abnormal deposition of iron pigments in the skin could be found

Discussion

We have described here four patients in whom there appeared to be a constant association of a dermatosis with a lowering of their serum (or plasma) calcium levels, the condition always being reversible by raising the calcium to normal We are not aware that this matter has been reported before in these terms, although it is perhaps not surprising in view of the known associations between hypocalcæmia and other skin lesions These known associations, mentioned in the introduction of this paper, have occurred when the hypocalcæmia was due to hypoparathyroidism or steatorrhœa. In the cases we describe, these ætiologies are also concerned That it is the lowered calcium level that is the main cause of the skin lesions seems quite clear, for not only are there several causes of hypocalcæmia, but it seems to be immaterial which particular means was used for raising the calcium to normal. For instance, among these have been the spontaneous return of the patient's parathyroid function, injections of crude parathyroid extract obtained from animals (parathormone), injections of calcium gluconate, and oral treatment with pure calciferol, pure D H T, or irradiated ergosterol (AT10) In most instances no other treatment than that mentioned above was given at the time. Local treatment to the skin consisted in bland applications throughout

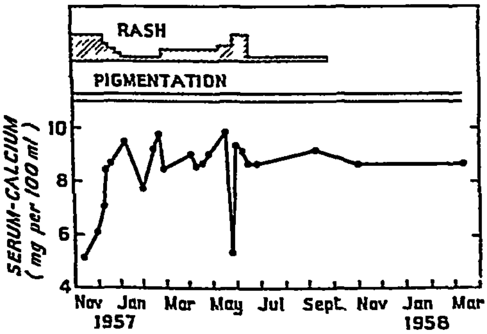

Fig 6—Case 4 relation between serum-calcium level and intensity of eruption.

The acute fall in serum-calcium during May, 1957, coincided with a change of treatment to sterogyl, which in the dosage used proved to be ineffective. The serum-calcium level rose again when pure calciferol was reintroduced

Clearly these skin lesions are an uncommon complication of hypocalcæmia. Apart from these four patients we have so far observed only two further cases in which itching and skin disease developed together with temporary hypocalcæmia. We think these are probably true examples of the phenomenon, but the investigations are inadequate for publication here There must also be a strong and constant individual factor involved, for the patients mentioned here have always had the rash when we know, or can presume, that their calcium was low It is clearly important to consider this possible cause of skin disease, especially bearing in mind that the treatment with vitamin D is very adequate and that there seems in such cases to be no alternative treatment.

We wish to stress strongly that classical signs of tetany do not need to be present with marked hypocalcæmia This is a well-known clinical observation, although published reports do not stress it. Of our cases, case 1 showed this feature conspicuously, for she was repeatedly observed over a period of three months with very low calcium levels, but never manifested positive Trousseau or Chvostek signs, spontaneous cramps, or carpopedal spasms It was fortunate that in her particular case we were expecting her calcium to fall owing to her having had a large parathyroid tumour removed and having with it very severe bone changes In two of our other cases it is painfully apparent that we were much slower to make this diagnosis We can only suggest that if an adult patient with skin disease and no signs of tetany has a scar on the neck or is less than 5 ft tall, the plasma-calcium should certainly be determined—perhaps sometimes in even less obvious circumstances

Impetigo herpetiformis was first described by Hebra (1872) and is a pustular dermatosis associated with fever and severe prostration. Four of his five cases died. Some hundred cases are now recorded, and these were reviewed by Hvidberg (1957) The disease is more common in women, though cases are recorded in men Women very often acquire the disease, or recurrence of it, during or immediately after pregnancy A striking proportion of women have a history of thyroidectomy Beek (1951) records typical hypoparathyroidism in twenty-four out of fifty-seven cases He concludes that some cases are due to endocrine imbalance, while some are caused by an infection While this severe pustular disease bears no clinical resemblance whatever to the cases of " hypocalcæmic dermatitis " which we have described, the relationship to parathyroid function seems to be more than a coincidence. One of Hvidberg's cases, a woman with typical impetigo herpetiformis in pregnancy, proceeded to have attacks of generalised erythroderma twelve years later

Many workers have considered the dermatological significance of calcium metabolism. The subject was reviewed by Goldsmith and Hellier (1954), and Wiener (1955) mentions the anti-inflammatory action of calcium therapy in mustard-oil conjunctivitis experimentally induced in rabbits Calcium-gluconate injections have been used in the treatment of urticaria, pruritus, and eczema, with varying results The value of this mode of treatment may be explained on the basis of the work of Chambers and Zweifach (1947) These workers believe that calcium ions are required to restore the damaged cement substance which serves in the densification of vessel walls

Calcium metabolism has been studied in many other dermatological conditions The fact that calciferol itself, or perhaps the mild hypercalcæmia resulting from its administration, can profoundly affect the skin reactivity to disease processes is quite obvious from the common clinical experience of the remarkably beneficial effects of calciferol in lupus vulgaris, though this is rather a special case. Furthermore our case 2 was shown to be sensitive to dyed wool fibres only while she was hypocalcæmic. This situation may clearly be of practical importance in skin testing to external irritants In this paper we have not, however, attempted to explain the skin changes in cases of hypocalcæmia in terms of disordered skin physiology, since we have nothing to add to this difficult matter

Summary

In patients with diseases of three different ætiologies, severe skin changes were closely associated with temporary hypocalcæmia

In each case dramatic improvement occurred, often repeatedly, when the plasma (or serum) calcium became normal or was restored to normal with vitamin D, parathyroid hormone, or calcium-gluconate injections

These facts are considered to be highly suggestive of a close association between " skin health " and plasma-calcium levels in certain patients

Since the presence of hypocalcæmia may not be clinically obvious from the presence either of overt tetany or of a known cause of tetany, this possibility should be borne in mind, especially as treatment is so satisfactory.

We wish to thank Dr J F. Stokes for permission to publish case 3, and Dr P J Hare for case 4. Mr A Bligh kindly took the clinical photographs and Mr V K Asta drew the diagrams.

OVERWEIGHT IN PREGNANCY

ANN MULLINS

M A Oxon, M B Lond, D R C O G

FORMERLY RESEARCH REGISTRAR, ST JAMES' HOSPITAL, BALHAM,
LONDON, S W 12

THAT overweight in pregnancy increases the risk to the fœtus has long been known (Smith 1916).

Matthews and der Brucke (1938) studied 200 pregnant women whose weight was over 200 lb 75% of them had some complication of labour. They showed a pronounced increase in the incidence of pre-eclamptic toxæmia, malpositions, long labour, maternal distress, and operative delivery. These findings were confirmed by Odell and Menger (1945). Tompkins et al (1955) found that patients 20% or more overweight or underweight were especially likely to develop pre-eclamptic toxæmia. Williams (1957) found that in cases of pre-eclamptic toxæmia the patients' initial weight as well as weekly gain during pregnancy were on average higher than normal.

Hamlin (1952, 1953) found that one of the most important factors in the prevention of eclampsia and pre-eclamptic toxæmia was control of diet and weight gain in pregnancy. He reported that by this means he had reduced the incidence of eclampsia from 1 in 500 to 1 in 7000.

Another danger of excessive weight gain in pregnancy is that the patient may remain permanently obese (Gurney 1936, Greene 1939, Sheldon 1949, Richardson 1952). In a personal series of 300 obese parous women attending a medical outpatient department, 226 (72%) stated that their obesity dated from pregnancy.

Only 45 of these had shown any previous tendency to obesity. In all but 30 the obesity had increased with every pregnancy. Moreover, there seems little doubt that their maternal obesity seriously impaired their health. 50 of them, seen consecutively, were matched for age and sex with 50 medical outpatients who were not obese. It was found that in the previous five years the obese group had had three times as many hospital appointments as the non-obese group, chiefly in the departments of gynæcology, surgery, physical medicine, and casualty. They had also been admitted to hospital more frequently, chiefly for minor gynæcological procedures. There is growing evidence that successful treatment of their obesity has improved the general health of these women and considerably reduced the frequency of their attendances at hospital.

Hamlin (1952, 1953) believes that primiparæ should not gain more than 8 lb (3 6 kg) between the 20th and 30th weeks of pregnancy. Hughes (1951) stated that a gain of more than 1 lb per week after the fifth month of pregnancy pointed to the need for close observation of the patient. A woman whose initial weight for height is more than 25% above any "standard" table is, by general agreement, overweight, and a weight gain of more than 28 lb during pregnancy is generally regarded as excessive. All the patients studied here were outside these standards, many of them considerably.

Sheldon (1949, 1953) and Richardson (1952) agreed that excessive increase of weight during pregnancy was due to increased appetite and stressed the possible importance of psychogenic factors. A patient in the present series stated that she always knew when she was pregnant, even before the first missed period, because she felt unusually hungry. Many patients who gain excessive weight in pregnancy feel hungry all the time. 100 consecutive patients in the present series were asked about this and 52 admitted to it. Others found that the frequent ingestion of carbohydrate was the best way to control nausea. A woman who normally controls her appetite for the sake of her figure may regard her inevitable change of shape during pregnancy as a justification for "letting herself go", she may believe that she must "eat for two", or fear that, by depriving herself, she is depriving the child. Lastly, many women who give up work during pregnancy are bored while waiting for their babies, they find themselves at home all day, surrounded by food, and eating helps to pass the time.

Material

This is an account of the management during pregnancy of 25 multiparous patients each of whom had, during one or more previous pregnancies, gained 42 lb or more, and of 10 primiparous patients who, in the first five months of pregnancy, gained a minimum of 20 lb. 15 of the patients in the multiparous group were being treated by me for obesity when they became pregnant, and, of these, 7 had reached normal weight. The remaining 10 multiparæ were referred from the antenatal clinic because of their histories of excessive weight gain, and, of these, 7 were obese. All the primiparous patients were referred from the antenatal clinic on account of excessive weight gain.

Methods

These patients were all treated in the obesity clinic, which is part of the medical outpatient department of St James' Hospital. As far as possible they were seen immediately after their visits to the antenatal clinic.

At the first visit a medical history was taken and the patient was fully examined. In addition, information was sought concerning appetite and food habits and the kind of life the patient led, so that her eating habits could be adapted to it. Special note was taken of food preferences and of cravings for special articles of food. A history of obesity in the patient's family was also recorded.

Advice was then given about the diet. In all cases a low carbohydrate diet was recommended. Typical advice was "Eat not more than two slices of bread per day and nothing else whatever containing flour, sugar, or potato. Eat as much as you like of meat, fish, eggs, vegetables (other than potato), salad and fresh fruit." Patients who were eating large quantities of foods such as rice or nuts were advised to reduce their intake of these. It was often necessary to enlarge on details—for example, to emphasise that all biscuits and bread contain flour, and that an article of food may not be eaten just because it is advertised as "non-fattening" or "slimming".

Drugs were only used when it was considered that the patient's weight could not be controlled without them. 4 of the multiparous patients had been on dexamphetamine sulphate before they became pregnant, and these were kept on the drug throughout. 2 other multiparæ and 1 primipara were started on dexamphetamine sulphate during pregnancy. There is no evidence that this drug is contraindicated in pregnancy, and no ill effects were observed.

These patients were all seen by me at intervals of one to four weeks. The interval depended on the degree of difficulty experienced by the patient in controlling her food intake, and on her weight change between visits.

Results

During the pregnancies the 25 multiparæ gained an average of 18 lb (standard deviation 10 lb) compared with an average of 59 lb (standard deviation 16 lb) in previous pregnancies when their weight had been unsupervised and 49 lb (standard deviation 14 lb) in pregnancies where their weight had been supervised in the antenatal clinic. Only 3 of them gained 28 lb or more, and 2 of these had already gained 24 and 26 lb when referred to the obesity clinic at 20 and 19 weeks respectively.

The 3rd had had uncontrollable craving for chocolate since childhood, and this increased during pregnancy. She gained 36 lb during this, her third, pregnancy, which was the largest gain in the group. During her second pregnancy she had gained 49 lb despite attempts in the antenatal clinic to control her weight. During her first pregnancy she had received no instruction regarding her weight and had gained 63 lb.

Among the 10 primiparæ and 10 multiparæ referred from the antenatal clinic on account of excessive weight gain, the average weekly gain fell from 1·8 lb (standard deviation 0·4 lb) to 0·6 lb (standard deviation 0·2 lb) although they attended the obesity clinic in the second half of pregnancy, when weight gain is normally greatest. None of these patients gained more than 14 lb after the 20th week of pregnancy, or more than 9 lb during the 20–30 week period. The 10 multiparous patients had, during their previous pregnancies, gained excessive weight throughout.

All the 35 pregnancies in which the weight gain was controlled in the obesity clinic ended in the normal delivery of a healthy infant. In the previous 43 pregnancies of these women in which the weight gain had not been successfully controlled, there had been 5 stillbirths, 6 forceps deliveries, 3 cæsarean sections, and 8 cases of pre-eclamptic toxæmia necessitating admission to hospital.

Discussion and Conclusion

Experience in treating obesity has shown that advice, however sound, is seldom sufficient for satisfactory weight loss when it is given only once. The patient must be seen at short intervals to reinforce and repeat the advice and to encourage, praise, or admonish. In difficult cases it is often necessary to discuss in detail the patient's eating habits, to vary the diet in accordance with her life circumstances, to suggest recipes and methods of food preparation, and to encourage the patient to try new articles of food. repeated encouragement and advice are especially necessary in such cases because long-standing habits are hard to change, and the attempt often causes the patient much anxiety.

By these methods many obese patients, hitherto regarded as "untreatable", can be helped to regain normal weight. The same principles have been applied successfully to patients with excessive weight gain in pregnancy, not controlled by advice in the antenatal clinic. Since pregnancy is a common starting-point of obesity in later life, the control of excessive weight gain in pregnancy is important, not only for the outcome of the pregnancy, but also for the future health of the patient.

This work was done during the tenure of a Nichols research fellowship of the Royal Society of Medicine.

TOTAL EXCHANGEABLE POTASSIUM IN INFANTILE MALNUTRITION

ROGER SMITH*
M B Cantab

J C WATERLOW
M D Cantab

From the Medical Research Council, Tropical Metabolism Research Unit, University College of the West Indies, Jamaica

ONE of the characteristics of severe protein malnutrition in infants is a profound electrolyte disturbance (Gomez et al 1957). Balance experiments (Hansen and Brock 1954) have provided indirect evidence of a depletion of potassium and an accumulation of sodium in the body. These changes are reflected in muscle, as shown by the analysis of biopsy specimens (Frenk et al 1957, Waterlow and Mendes 1957). Further evidence of potassium depletion has now been obtained by measurement of total exchangeable potassium (Ke).

Since the original observations of Corsa and his associates (1950), many studies on exchangeable potassium have been made in adults, in both health and disease (O'Meara et al 1957, Edelman et al 1958, Flear et al 1958). Studies have also been reported in normal neonates (Christian and Talso 1959), normal infants and children (Corsa et al 1956), and in children with the nephrotic syndrome (Gribetz et al 1954). We have, however, been unable to find any record of such measurements in malnourished children.

Method

^{42}K,† as a sterile solution of potassium chloride, was given by intramuscular injection in a dose of 1 µC per kg body-weight.

The amount injected must be accurately known. This was achieved by weighing the bottle containing the solution before and after filling the syringe. The syringe was washed out after the injection, and the radioactivity measured in the washings.

Exchangeable potassium (Ke) was calculated from measurements on the urine.

Blood was not used, because an unjustifiably high dose of isotope would be needed to obtain a measurable level of radioactivity. Moreover, in these severely ill children the number and size of blood samples removed should be kept to a minimum. Wherever possible three separate samples of urine were collected at intervals from 22 to 31 hours after the injection. In all the later measurements the urine was concentrated about five times by evaporation in order to increase the accuracy of the counting. Radioactivity was measured with a well-type scintillation counter, urinary potassium was measured with the flame photometer.

Exchangeable potassium is given by the formula

$$\text{Ke (mEq)} = [(\text{counts injected}) - (\text{counts lost between injection and measurement})] \times \frac{^{39}\text{K concentration in urine (mEq per litre)}}{^{42}\text{K concentration in urine (counts per litre)}}$$

TABLE I—PRELIMINARY STUDY OF EXCHANGEABLE POTASSIUM IN 12 CASES OF INFANTILE MALNUTRITION

Patient no	Age (months)	Weight (Kg)	Total Ke, mEq	Ke per Kg body-weight, mEq
Early cases				
1	12	4 90	145	29 6
2	6	5 35	159	29 7
3	5	3 18	91	28 6
4	5	3 35	152	45 4
5	10	5 95	170	28 6
6	10	4 22	72	17 1
7	20	7 40	209	28 3
8	9	5 30	86	16 2
Recovered cases				
9	18	6 84	264	38 6
10	18	6 10	287	57 0
11	7	6 35	203	31 8
12	18	4 10	157	38 3

In most cases a complete collection of urine was made from the time of injection to the time of measurement The urinary loss of isotope was then measured directly and averaged 4 7% of the injected dose in the first 22 hours When for any reason urine collections were incomplete the urinary loss of isotope was estimated as 5% of the dose

No allowance has been made for fæcal loss

In the adult this is normally insignificant compared with the amount lost in the urine (Corsa et al 1950) However, in infants with diarrhœa and coexistent potassium depletion the fæcal loss of potassium may exceed the urinary loss The effect of neglecting fæcal loss will be to increase the apparent value for Ke In adults it has been recommended (Corsa et al 1950) that oral potassium intake should be restricted during the period of measurement We did not think it justifiable to do this in our cases

In the present series, equilibration of injected ^{42}K, as judged by a constant specific activity in the urine, appeared to be virtually complete by 22 hours In adults 95% equilibration occurs between 18 and 40 hours after injection, even in the presence of œdema (Corsa et al 1950, Blainey et al 1954, O'Meara et al 1957)

Material

The cases studied presented the clinical characteristic of severe malnutrition that have been described in previous reports from Jamaica (Waterlow 1948, Jelliffe et al 1954)

Results

A preliminary study was made in twelve cases (table I) The urinary loss was not measured directly, but was assumed to be 5% of the dose The mean Ke in eight malnourished babies soon after admission to hospital was 27 9±3 0 mEq per kg body-weight, and in four recovered cases 38 9±2 8 ‡ mEq

The results in a second series of twenty-two cases are summarised in table II The mean Ke in six babies who had been in hospital for less than a week was 31 6±3 2 mEq per kg In sixteen children who had been in hospital for more than a week the mean Ke was 41 4±1 3 mEq

The results expressed in this way indicate that on the average the malnourished babies had lost about 25% of their exchangeable potassium

In our cases the serum-potassium level gives no indication of the presence of extent of body-potassium depletion This agrees with previous observations, such as those of Moore et al (1954) on adults

Muscle, on the other hand, reflects more closely the changes in Ke In thirteen cases muscle biopsies were done at the time of measurement of exchangeable potassium The muscle potassium content was measured by the method previously described (Waterlow and Mendes 1957), and related to D N A (desoxyribonucleic acid) phosphorus, as the most constant cellular constituent

Fig 1 shows that there was a good deal of variation, but even in this small number of cases a significant correlation was obtained between Ke and the potassium content of muscle Red-cell potassium seems not to vary in the same way as muscle potassium (V G Wills, unpublished data) From the practical standpoint this is unfortunate, since it would be so much easier to measure

TABLE II—EXCHANGEABLE POTASSIUM IN 22 CASES OF INFANTILE MALNUTRITION

Time in hospital	No of cases	Mean Ke per Kg body weight (mEq)
Less than a week	6	31 6±3 2
More than a week	16	41 4±1 3

There is evidence that one effect of cellular potassium depletion is an inability on the part of the kidney to concentrate hydrogen ion after an acidifying dose of ammonium chloride (Clarke et al 1955, Smith 1959) This test was done in twenty-one cases immediately after the measurement of exchangeable potassium Fig 2 shows a close correlation between the extent of potassium depletion and inability to acidify the urine

Discussion

Our observations confirm the original finding of Hansen and Brock (1954) that infants with protein malnutrition are severely depleted of potassium They suggest, moreover, that this depletion affects cell function in at least one organ, the kidney On the other hand the quantitative interpretation of the results is not easy, since no standard of reference is entirely appropriate In well-nourished children with gastroenteritis there is a loss of potassium in excess of the loss of other tissue components (Darrow 1946) But in these malnourished infants it may be argued that the reduction in Ke merely reflects a reduction in tissue mass, and not a *specific* depletion of potassium To some extent this is true measurements of body water (Smith, to be published) have shown that even in the absence of œdema the body of the malnourished baby contains an increased proportion of water, and hence a decreased proportion of solids In the present

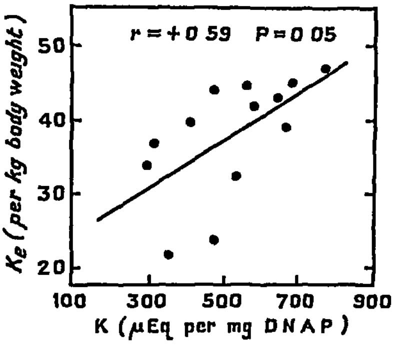

Fig 1—Relationship between exchangeable potassium and muscle-potassium content

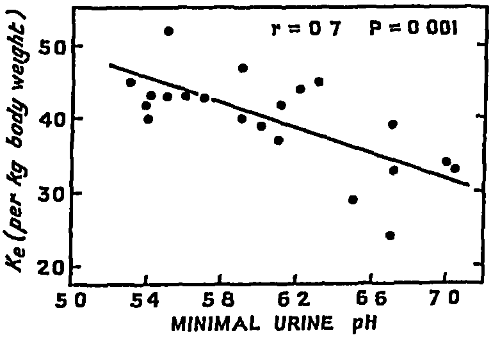

Fig 2—Relationship between exchangeable potassium and minimal urinary pH after a standard load of ammonium chloride

study we have not measured Ke and total body water at the same time in the same case. Therefore we are not able to state with certainty whether the depletion of potassium is greater or less than that of the body solids as a whole In one tissue, muscle, there is evidence of a specific or extra loss of potassium, since the ratio of potassium to non-collagen nitrogen is significantly lower than in normal muscle, even after 7–10 days treatment (Waterlow and Mendes 1957) This fits in with Hansen and Brock's (1954) finding that during recovery more potassium was retained than nitrogen (in comparison with the ratio of these two elements in normal tissues), but it cannot be assumed without further investigation that a specific loss of potassium occurs from organs other than muscle.

---

‡ Standard error of the mean

From the practical point of view, these measurements suggest that the malnourished infant may have lost at least a quarter of its exchangeable potassium, thus an infant of 6 kg might have a deficit of some 60 mEq In this unit we normally give a potassium supplement of about 20 mEq per day (as potassium acetate), in addition to the 15 mEq or so supplied by the diet Even when muscle analysis indicates that the body is depleted of potassium, balance measurements show that retention of ingested potassium is by no means completely efficient Supplementary potassium must therefore be continued for a considerable period—perhaps for 10 days or more Restoration of a normal serum-potassium level must not lead one to assume that the body stores are repleted

Summary

In infants with severe chronic malnutrition the total exchangeable potassium (Ke) was measured by the isotope dilution method Ke per unit body-weight was found to be reduced by 25–30% After recovery normal levels were found

The reduction in Ke was accompanied by a loss of potassium from muscle, and by inability to produce an acid urine in response to a test dose of ammonium chloride

The serum-potassium level is no guide to the extent of depletion of body-potassium

In treatment it is necessary to continue potassium supplements for at least 10 days, since even in the presence of depletion potassium is incompletely retained.

New Inventions

A SPIROMETER FOR MEASURING THE FORCED EXPIRATORY VOLUME WITH A SIMPLE CALIBRATING DEVICE

THE forced expiratory volume (F.E.V.), or amount of air a subject can exhale forcibly in a short time (usually 0 75 sec or 1 sec.) after a full inspiration, is now widely used as a measure of ventilatory capacity (for terminology see Gandevia and Hugh-Jones[1]) It can be measured either by a recording spirometer with fast recording kymograph[2] or with a simple spirometer, the rotation of whose wheel shows the volume expired. The volume over a fixed time period is recorded by a pointer lightly held at the centre of this wheel and restrained from moving with it during the selected time by a solenoid actuated by an electronic timer[3]

The latter type of apparatus, of which an improved form is described here, has the advantage of providing a reading without the necessity of analysing a paper record, and is thus well suited both for routine use in the clinic where an immediate answer is needed and for field surveys where large numbers must be rapidly examined Up to the present a major disadvantage of this type of instrument has been that it is possible for errors in the electronic timer and relay to go undetected The testing device described here overcomes this difficulty

Spirometer

The spirometer (fig 1) has a 7-litre bell and a breathing tube of 1³/₈ in. diameter set at an angle of 45° to the canister so that compensation can be made for tables of different heights This tube has a small inspiratory valve in the lower side to prevent

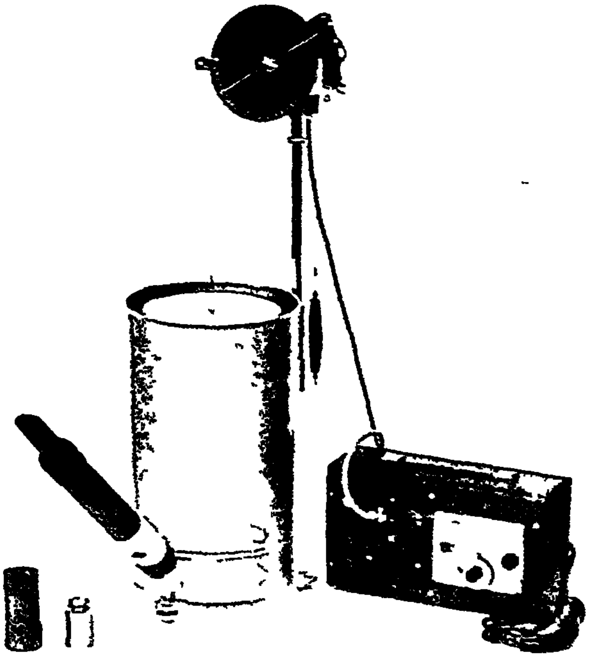

Fig 1—The apparatus with calibrating device

---

[1] Gandevia, B, Hugh-Jones P *Thorax*, 1957, 12, 290
[2] Kennedy, M C. S *ibid* 1953, 8, 73
[3] Gaensler, E. A *Science*, 1951, 114, 444

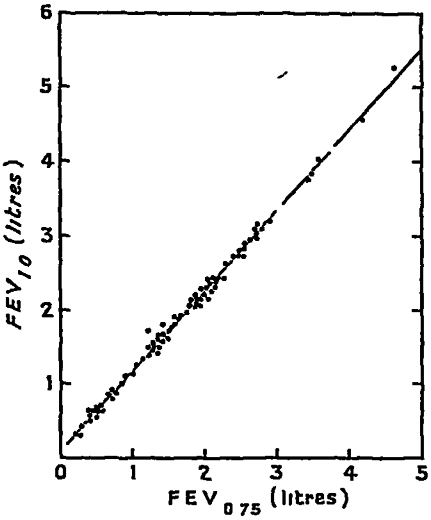

Fig 2—The relationship between F E V$_{0\ 75}$(x) and F E V$_{1\ 0}$(y) in 100 subjects The straight line is the linear regression $y=1\ 08x+0\ 09$

aspiration of water by the subject The black bakelite wheel on the spirometer head has a double white engraved scale, the outer one in litres and 0 05 litre, and the inner one, for recording the indirect M B C, in litres per minute The latter scale (the E F R$_{40}$ of Kennedy) is the F E V$_{0\ 75}$ multiplied by 40, and should therefore only be used when the timer is set for 0 75 sec Both scales are corrected to B T P S, assuming a water temperature of 20°C Their accuracy at this temperature is within ±1 5% A change of ±5°C will cause an error of less than ±2% in the readings, and it is therefore usually unnecessary to correct them further

There are two pointers, the fixed one indicating the vital capacity and the movable one the F E V The back end of the movable pointer engages a catch operated by the solenoid which is only energised during the time period set on the electronic timer The timing cycle, which is adjustable, is initiated through a microswitch on the head immediately 100 ml of air has entered the spirometer This 100 ml volume delay is incorporated to reduce errors in readings due to the subject hesitating at the start of expiration It makes no appreciable difference in normal breaths as the pointer is arranged not to pass the zero until this volume has been expired

The timer, manufactured by Venner Electronics Ltd, is mains operated from an alternating current supply of 200–250 volts and 40–60 cycles per sec It can be set to operate over any time periods from 0 5 to 3 0 seconds

The Calibrating Device

This consists of a 1-in length of 'Tufnol' rod bored to $^1/_2$ in internal diameter and made to attach to the spirometer in place of the breathing tube, and a 500 g weight which is hung on the hook at the bottom of the existing counter-weight The tufnol tube is accurately machined, and damage to its bore will affect the calibration

With the calibrating tube and extra weight in place the spirometer bell is gently depressed until the block on the spirometer wheel makes contact with its stop It is then suddenly released and air is drawn through the orifice into the bell at a flow-rate which is constant for a given spirometer, tube, and weight, the machine will therefore record its own F E V, the values of which, corresponding to time intervals of 0 75 and 1 0 second, are supplied with each apparatus The mean of three readings should agree with the appropriate stated value within ±0 05 litre and the individual readings should not deviate from each other by more than this amount, as the repetitive accuracy of the timer is ±2% If the mean lies outside these limits the cause should be sought and if necessary the timer adjusted

As the air-flow rate at the end of the first 0 75 or 1 0 second of a forced expiration is relatively very low compared with the earlier part, an error in the timer giving a change in the calibration within these limits has been found to affect the recorded F E V less than ±0 6%

Time Interval

The F E V is commonly measured over either 0 75 or 1 0 second and in order to relate these values we studied 100 subjects using a special apparatus with two pointers operated by separate timers The group comprised 20 members of the staff, 60 employees of a light industrial factory for men partially disabled by coalworkers' pneumoconiosis, and 20 inpatients mainly suffering from pneumoconiosis and chronic bronchitis

Fig 2 indicates that the relationship throughout the whole range of values can be adequately described for practical purposes by a straight line (r = 0 998) However the tendency for the scatter to increase at the higher values of F E V suggests that a logarithmic relationship would give a better indication of the range of accuracy of conversion that can be attained Fig 3 shows the least-squares regression fitted to the logarithms of the F E V values, and 95% fiducial limits, for predicting the F E V$_{1\ 0}$(y) from the F E V$_{0\ 75}$(x)

Also shown is the simple linear regression

$$y=1\ 08x+0\ 09,$$

which it will be seen lies within the 95% limits and will lead to perfectly acceptable values at all points in the scale

The same is true if the linear regression

$$x=0\ 92y-0\ 07$$

is used to predict the F E V$_{0\ 75}$ from the F E V$_{1\ 0}$

Thus we may predict the F E V$_{1\ 0}$ from the F E V$_{0}$ simply by taking 108% of the latter and adding 0 09 litre to it Similarly the F E V$_{0\ 75}$ can be predicted from the F E V$_{1\ 0}$ by taking 92% of the F E V$_{1\ 0}$ and subtracting 0 07 litre

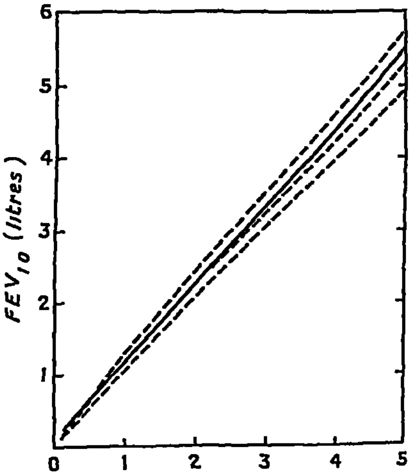

Fig 3—The relationship between F E V$_{0\ 75}$(x) and F E.V$_{1\ 0}$(y) Continuous line Linear regression $y=1\ 08x+0\ 09$ Broken lines: Logarithmic regression $y=1\ 191x^{0\ 931}$ with 95% fiducial limits

Since this work was done Miller et al[4] have published data on the relationship between the forced vital capacity and F E V$_{0\ 5}$, F E V$_{0\ 75}$, and F E V$_{1\ 0}$ From these it is possible to calculate approximately the relation between the F E V$_{0\ 75}$ and F E.V$_{1\ 0}$ and this agrees well with our findings

The F E V Test

The spirometer bell is fully depressed and the movable pointer set to about 0 5 litre (The exact figure is immaterial provided it is less than the F E V measured) The seated subject is asked to inspire maximally, then to place his lips firmly around the mouthpiece, and to blow as hard as possible There is good evidence that the first and perhaps second attempts tend to be low compared with the subsequent ones, and it is therefore advisable to allow the subject two trial blows and then to average the following three consecutive ones provided they are technically satisfactory If desired each breath can be followed through to maximal expiration to obtain the vital capacity although this adds considerably to the fatigue of the test. If the vital capacity is not measured, no more than half a minute's rest need usually be allowed between blows A nose clip is unnecessary

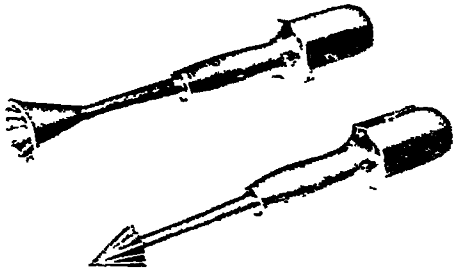
A REAMER AND BURR FOR ARTHRODESIS OF THE METATARSOPHALANGEAL JOINT

These instruments are designed to facilitate arthrodesis of the metatarsophalangeal joint of the hallux in cases of hallux valgus and hallux rigidus After exposure of the joint the metatarsal head is shaped into a conical peg by means of the specially designed reamer Preliminary shaping with an osteotome or bone-cutting forceps may be required when the joint surfaces are hard and eburnated. The base of the proximal phalanx is then hollowed out with the large burr The reamer and burr are complementary, allowing the shaped metatarsal head to be jammed into the hollowed-out base of the proximal phalanx, and thus impacting the two bones firmly together Firm fixation is obtained from a screw inserted obliquely across the joint.



These instruments have been produced for me by Messrs Down Bros and Meyer & Phelps Ltd., 32, New Cavendish Street, London, W 1, and the London Splint Co , 67, Weymouth Street, London, W 1

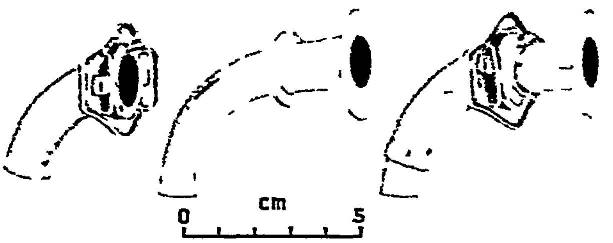
A MODIFICATION OF THE COLLEDGE LARYNGECTOMY CANNULA

During the first days after operations involving total laryngectomy the patient has to wear some form of rigid tube in the tracheostome to ensure a clear airway and give proper access for suction and toilet. A detachable inner component is essential to facilitate frequent cleaning without removal of the outer tube and dressings

Since such a tube should extend forwards well clear of the inevitable heavy dressings, it usually has two perforated flanges set at right angles to the lumen The first of these is attached to the tube at skin level, being kept in position by tapes, and the second is at the upper end to prevent dressings from falling across the orifice For about 36 years these requirements have been met in this country by the Moure's modified or extended type of Lombard laryngectomy cannula. But, by reason of its weight, length, and rigidity, this tube is unsatisfactory for continued use once the dressings are discarded When a laryngectomy tube is required at this or any later postoperative stage, the shorter, lighter, and more suitable Colledge laryngectomy cannula is generally used.



Although satisfying basic requirements, the extended Lombard cannula is open to criticism because of its relative weight, single size, small calibre, and rigidity The conical base at skin level was perhaps originally designed with the idea that constant pressure on the healing suture line would produce ultimate dilatation of the tracheal orifice. But the reverse effect may readily be produced, the pressure delaying healing at the mucocutaneous junction, with consequent fibrous contracture of the tracheal orifice.

In view of these disadvantages, and for the sake of economy and simplicity, it is useful to equip one of the three existing sizes of the Colledge cannula with an inner component, thus forming a composite laryngectomy tube The inner component can be extended at either end to keep the airway open during the immediate postoperative period, when heavy dressings and frequent cleansing of the tube are essential As soon as the sutures are out and dressings are no longer required this inner tube may be discarded, and after a further short interval the outer tube may also be dispensed with in many patients

To meet these requirements a flanged silver-alloy inner component, extended at both ends, has been designed to fit the standard medium size Colledge laryngectomy cannula (see figure) As shown, the cannula has also been fitted with a rotating catch on its upper margin to hold the inner component in place. This catch is not essential since an elastic band or strip of tape may be used to prevent the inner tube from being displaced during the short period of heavy neck dressings

Specifications (for the medium size Colledge cannula) are

Weight of whole composite tube	1½ oz. (2 oz.*)
Length of inner tube	8·8 cm. (9·0 cm.)
Length of outer tube	5·5 cm (8·0 cm)
Length of tracheal extension	1·1 cm. (0·1 cm.)
Length of surface extension	2·2 cm. (1·5 cm.)
Smallest internal diameter of inner tube	1·0 cm (0·8 cm.)

Thus the composite Colledge tube is lighter and has a wider lumen than that of the Moure Lombard pattern A similar inner component has also been manufactured to fit the small size Colledge cannula, which is more suitable for women This smaller model reduces still further the weight and bulk without impairing the efficiency of the airway

The only practical points which have emerged from a thorough clinical trial are that the airway must be carefully watched when the inner tube is changed or cleaned, and that care must be taken to see that the inner tube is always fully inserted and secured Attention to these points presents no great difficulty provided that the nurses are well trained in the postoperative management of such cases

It is hoped that this inner component for the Colledge laryngectomy cannula will give a better airway with better healing of the tracheostome, greater comfort to the patient and possibly more economic use of existing equipment.

Messrs. Down Bros and Mayer & Phelps, Ltd., 32, New Cavendish Street London, W 1 manufacture the inner component in the two sizes quoted.

Reviews of Books

A Textbook of Surgical Physiology

R A Jamieson, M B, F R C S I, surgeon, Vale of Leven Hospital, A W Kay, M D, F R C S E, *professor of surgery*, University of Sheffield Edinburgh E & S Livingstone 1959 Pp 623 55*s*

Here is a sign of the times—a sign which will not be missed by the new generation now reaching surgical maturity—for the fact that this book has been written is an acknowledgment of the shift in basic surgical outlook Anatomy and the topography of technique are now less important for the surgical trainee than the repercussions not only of disorder but also of his own interventions It could be argued with some justice that he who knows physiology intimately is safer than the expert in anatomy there can be no guessing to make up for ignorance of biochemical principles when applying intravenous therapy, for instance, whereas the man who has to go down an unknown lane on a dark night at least has the opportunity of finding his way with the aid of a torch This book is therefore of considerable importance since it has no exact forerunner, the information it contains could be gleaned from many sources, but it has not previously been brought together in this way The conception of the whole work is as striking an achievement as its execution

The temptation to include more than is immediately necessary for the practice of general surgery must have been considerable, but the authors have avoided it, and because the emphasis is on general surgery ovarian physiology, except in the relationship of its hormones to breast cancer, is omitted, as is the central nervous system For the same reason, no doubt, readers are referred in a useful chapter on the heart to original sources for intimate details of heart-lung machines, though the mechanical principles of the artificial kidney are described succinctly but adequately in a later chapter on that organ The style is brief and to the point, the cover comprehensive, the authors' apologies for inadvertent omission seems to have been superfluous They have done a neat job and a fine work has now been added to others which have emanated from Glasgow to make surgical study more rational, and it is pleasing to note the credit given by the authors to the man who has done much to bring this about—*Prof C W Illingworth*

Heavy Metals and the Brain

John N Cumings, M D, F R C P, professor of chemical pathology in the University of London at the Institute of Neurology Oxford Blackwell Scientific Publications 1959 Pp 161 32*s* 6*d*

This book is arranged in three sections the first and largest is concerned with copper and hepatolenticular degeneration, and the other two deal with the nervous manifestations of poisoning by mercury and lead Its thoroughness is indicated by the fact that, of the 150-odd pages of text, no less than 30 are devoted to a bibliography of some 900 references Such a flood of references is a handicap to smooth literary composition, but the book is nevertheless highly instructive Morbid anatomy and what might be called " gross chemical pathology " are fully described, together with clinical and therapeutic data Less attention is given to biochemical mechanisms at the cellular level, and some general aspects of the relation of heavy metals to enzymes might have merited inclusion Professor Cumings has undoubtedly provided an excellent source-book on the topics he has chosen

Atlas of Roentgenographic Measurement

Lee B Lusted, associate professor of radiology, University of Rochester School of Medicine, Theodore E Keats, professor of radiology, University of Missouri School of Medicine Chicago Year Book Publishers London Interscience Publishers 1959 Pp 176 68*s*

Experienced radiologists base their judgment largely on appearances, but the statement that " it appears normal " often seems lame and unconvincing to clinical colleagues and students This atlas aims to help radiologists in such circumstances The authors have tabulated from published data and from their own work, the average size and normal variation of most of the measurable body structures Amongst the more useful features are measurements of the cerebral ventricles and the position of the cerebral vessels as seen by arteriography The relationships of all the major joints should prove particularly valuable, especially when assessing congenital subluxation of the hip and abnormalities around the ankle joint. The text includes the standard radiographic positions by means of which such measurements can be made Many pages are devoted to the various measurements of the heart, female pelvis, and fœtal head, and there are excellent tables on the maturation of the skeleton

Fear, Punishment, Anxiety and the Wolfenden Report

Charles Berg London Allen & Unwin 1959 Pp 120 20*s*

One of the late Dr Charles Berg's exceptional gifts was his ability to explain difficult concepts in terms that ordinary people could follow, and this despite the fact that many of the things he understood well are rather apt to provoke resistance in readers The four essays in this book are of his usual high standard The first is a critical evaluation of that part of the Wolfenden Report which deals with homosexuality In terms of great severity, he criticises both the methods and some of the conclusions of the committee Resignations, minority reports, and reservations, all taken as disagreement amongst themselves, are explicable to the analyst only as the inevitable result of personal ignorance But some of the recommendations are praised and the fact that the committee has shed a great deal of light into dark places is acknowledged

Berg's second essay, on the psychology of punishment, is an admirable contribution, in which punished and punisher are discussed in terms of the unconscious forces that shape belief and conduct We trace the footsteps of the Roman citizen enjoying the spectacle of criminals being thrown to the lions, or being publicly castrated, down to the present day with its emphasis on psychological suffering and find it is we ourselves who stand in the Roman's shoes " Punishment *means* destruction why delude yourselves " the author asks disturbingly

The last third of the book is devoted to an attempt at understanding the nature of anxiety and fear This makes harder reading and is rather speculative in places The whole book is interesting and rewarding, not least for those whose chief concern lies outside present psychological thought

Honour a Physician

Philip Auld London Hollis & Carter *1959 Pp 270 16s*

In form an anecdotal narrative, this book is in effect a bitter and sustained indictment of the National Health Service as a corruptor, primarily of patients, secondarily of doctors, and a destroyer of family doctoring, good clinical medicine, and continuing *medical care* It has long been known that some citizens are devoid of citizenship and respect for truth and that a minority lack manners or decency of any kind The indictment's chief count is that to these people has been given the right to demand visits of their doctors at any hour of the year without cost to themselves or penalty for abuse The doctor's only remedy is to have incorrigible offenders removed from his list, thereby dumping them on his neighbours Gluttony for certificates and medicines is stimulated, good patients become *shy of seeking the help they need*

" Dr Gatwood " has a social and a medical conscience, his heart is in his job, he welcomed the *Service*, but ten years of buffeting at the hands of patients, without help or recognition of his plight by Ministry, Parliament, Press, or B M A , drives him, reluctant, out of the Service into part-time industrial medicine and private practice Some of his colleagues beat less honourable retreats

The book demands earnest attention by the profession and by those in authority over the National Health Service, for the picture it paints is one that many people believe to be truly drawn

Toxæmia of Burns

Extensive burning is followed by serious illness and, espite advances in therapy, many patients still die The eneral effects are so profound that it is not surprising iat an embracing concept of toxæmia or autointoxica- on was put forward many years ago The idea is said [1]) have originated in 1876 in Petrograd, where Avdakoff eported that the blood of burned animals was toxic to thers Toxic products released from the burned skin r the blood are alleged to produce illness and even eath, but the number and variety of the toxins isolated rom time to time (toxalbumin, ptomaines, formic acid, mmonia, proteoses, peptones, histamine, methyl guani- ine, hydrocyanic acid, and many others) indicates either heir multiplicity or their elusiveness At one time the oncept led to the treatment of burns by tanning, which, y precipitating the proteins in the altered skin, was said o prevent absorption of their "toxic" products, but he tannic-acid treatment itself produced toxic effects, nd tanning—or at least tannic acid—is now discredited The concept of autointoxication held the field for over ifty years, but during the last twenty to thirty of these ears it lost much ground, mainly because advances in hysiological and pathological knowledge of burns have endered the theory less and less necessary and have led o the introduction of life-saving therapy—especially plasma-transfusion, antibiotics, and skin excision and grafting

The main facts about the hæmodynamic nature of burn "shock" and its relation to oligæmia have now been established Oligæmia is brought about mainly through the loss from the blood into the acutely inflamed burned area of large quantities of a plasma-like exudate, the redistribution of body-water is associated with changes in proteins and electrolytes which can lead to hypoproteinæmia, sodium depletion, and dehydration, renal failure and changes in the kidney are due to a lowered filtration-rate and renal ischæmia, and are accentuated by hæmoglobinuria, the hæmoglobinuria is due to acute red-cell destruction which produces red-cell oligæmia and anæmia and occasionally hæmolytic jaundice, whilst biochemical and metabolic disturbances involving carbohydrates, nitrogen, minerals, and vitamins are brought about by humoral or neurohumoral mechanisms in which the adrenal gland and especially adrenocortical hyperactivity are involved The burned skin rapidly becomes contaminated with bacteria of which *Streptococcus pyogenes*, *Pseudomonas pyocyanea*, *Staphylococcus aureus*, proteus, and various coliform bacilli are the most important, transient or intermittent bacteræmia is common, and not uncommon are septicæmic invasion and pneumonia, these are often responsible for "toxæmic" pyrexia, illness, and death, particularly in those surviving the first few days Nevertheless there is still no complete explanation of many effects of burning, such as the early hyperæmia of the lungs, stomach, bowel, kidneys, and other organs, early hyperpyrexia, and polypnœa, and many patients still die despite energetic medical and surgical therapy Although nearly all very extensively burned patients can be kept alive for a week or longer by modern fluid therapy, some die later—generally from pneumonia, other bacterial infection, or other causes which are sometimes obscure Are some deaths due to non-bacterial toxæmia?

If burn toxæmia is real it is certainly a less embracing cause of illness and a less important cause of death than was once believed Experimental findings are voluminous but conflicting Severe illness or death in normal animals has been observed after injection of extracts of burned skin or exudate [2–4] or the blood or serum of burned animals,[5–7] but other workers [1 8–11] have found no deleterious effects Some of these reports are likely to be invalid because there is doubt about the sterility of the material injected and bacteria may have been responsible Cross-circulation experiments [12–15] between burned and normal animals in which the normals became ill or died do not necessarily denote that a toxin was transferred from one animal to the other, because oligæmia in both animals could explain the results, while the beneficial effects of exclusion by ligation or excision of the burned part soon after burning [1 14 16 17] can just as well be explained by the prevention of gross burn œdema and consequent oligæmia Nevertheless various substances are undoubtedly released or newly formed after burning [18] These include hæmoglobin, potassium, nuclear nucleoprotein,[19] adenosine,[20–22] phosphate, and pentose, probably ribonucleic acid, abnormal proteins [23] including gelatin,[24] polypeptides (some with leukotaxic properties [25]), histamine,[24 26 27] and glycoprotein [28] Some of these are formed in or released from the burned skin and were detected in the skin or the local œdema fluid or the lymph draining the burned area, while others are released from heat-altered red cells The liberation of a skin proteinase[29] by heat-injured epidermis, the activation of other proteolytic enzymes,[30] and the release of peptidases[31] probably account for the proteins in the exudate Skin proteinase, polypeptides, and possibly other products may play a chemical intermediary part in producing, or (as Sevitt[32] suggested) more likely maintaining, the œdema of burns

The idea of toxæmia is being kept alive through the work of Simonart, Godfraind, and their colleagues in Belgium, Rosenthal and his colleagues in the U S A, and Federov and his colleagues in the U S S R Simonart, whose work dates back to 1928, has summarised his experience[33,34] In laboratory animals he divides the course following burning into three overlapping phases (1) *choc circulatoire precoce* (from generalised capillary dilation), (2) *deshydration*, and (3) *autointoxication*, which he believes is due to absorption of hydrolytic products of protein in the œdema fluid Not only was œdema fluid found to be toxic or lethal after injection, but various fractions extracted from the fluid, including euglobulin and peptones, had toxic or lethal effects That œdema fluid from burned rabbits is toxic to normal rabbits was established by Wilson et al[4] in Edinburgh in 1936 and was later confirmed by Cullumbine et al[35] in Manchester, but the lethal intravenous dose for rabbits was as much as 10 ml of exudate per kg body-weight, and for mice it was still more[36]

The work of Sol Rosenthal (not to be confused with Sandford Rosenthal, who also works on burns) dates back to 1937, and he too has summarised his latest work[37] Diffusates from burned skin, obtained both in vitro[24,26] and in vivo,[37,38] were studied

The in-vivo diffusate (œdema fluid) contained protein, protein split-products, sugars, salts, histamine, bradykinin, adenyl compounds, and other substances Injection of the fluid obtained from the burned skin of rats was lethal to other rats and to mice, and the speed of dying depended on the dose and route of administration The toxic property was heat-stable, dialysable (i e, non-protein) and partially precipitated by 80% ethyl alcohol, the toxic dialysable fraction contained peptides, polynucleotides, hexoses, and pentoses Histamine, bradykinin, and adenyl compounds were not related to this burn " toxin "

Thus both the Belgian and the American work on burn œdema supports the concept originally put forward by Pfeiffer[6,7] that toxæmia is due to the formation of degradation products of proteins If this is correct, and if proteins and local products of proteolysis also play a part in producing burn œdema, then the pathogenesis of burn inflammation is closely linked to the origin of toxæmia Of course the agents concerned would not be specific for burns, similar " toxins " would be formed in any inflammatory condition of the skin and probably other tissues, and the " toxæmia " would be a general disorder This would be an important link between, on the one hand, burn inflammation and toxæmia, and, on the other hand, peptides and serum-proteins which have been reported to act as chemical mediators of altered capillary permeability in other forms of experimental inflammation[39–44] Whether the toxicity of œdema fluid found experimentally is clinically important depends on whether the toxic products enter the circulation (this seems likely), how quickly they enter, how and how quickly the body deals with them, and their rate of destruction and elimination Experimentally, it is important to establish whether in-vivo inhibition of local proteolysis by drugs or other means can reduce the toxicity of œdema fluid

The work of Federov[45,46] and his colleagues in the U S S R is different They have extended the search for toxins into the interesting field of autoimmunisation. Autoimmunisation might explain certain obscure features, such as delayed eosinophilia after burning,[47] which might result from sensitisation following the absorption of altered proteins in the burned area. Federov holds that the body is flooded with antigens derived from the burned skin and that this is responsible for part of the burn illness, and that the subsequent autoimmunisation is a regular sequel of burning Certain antigens found in the blood and tissues of burned dogs were serologically similar if not identical with those in the burned skin, they were present in the circulation one or two days after burning and were detectable for up to fifteen days Skin antigens in blood were detected by immunisation of normal guineapigs with the serum of dogs taken at various times after burning Antibodies developing in guineapig serum after absorption of the serum with dog serum removed before burning were identified, using extracts of burned dog-skin as the source of antigen Autoantibodies, appeared in the circulation after the antigens had disappeared, and this raises hopes for therapy Complement-fixing titres of the order of 1 in 640 were found for saline extracts of burned skin six or seven weeks after burning The serum from dogs which had recovered from burns produced beneficial results in other burned dogs Moreover the sera of healthy dogs previously injected with blood from recently burned dogs (presumably containing skin antigens) had a pronounced therapeutic effect apparently greater than that of serum from non-immunised animals Serum from convalescent burned patients given in doses of 250 ml daily for three or four days to recently burned patients (as a supplement to other intravenous therapy) was said to have clinically impressive results Federov believes that the sera injected were immune sera containing antibodies against toxic antigens liberated from burned skin, and that the protective effect was partly or largely due to neutralisation of the flood of toxic antigens Some of the beneficial effect may be due merely to the injection of serum per se or to its containing antibacterial antibodies arising after infection of the burn Obviously confirmation and further work are necessary because of the hope of improving therapy and of saving some of those who at present succumb to extensive burns

Dental Caries

In a Bill of Mortality for London for one week in August, 1665, the cause of 118 deaths is given as " Teeth ",[1] and for the whole of that year no less than 2614 deaths were ascribed to " Teeth and Worms "[2], but as this was during the Great Plague, when endeavours were often made to conceal the true cause of death, the diagnoses are unlikely to have been particularly accurate Dental caries is not in fact a killing disease, and research into its pathology and prevention has no dramatic appeal Nevertheless it is responsible for much suffering, loss of working-time, and, quite possibly, chronic ill health[3] The principal school dental officer for Derbyshire said recently " Already there are children in the older age groups of school who are toothless and wear full sets of dentures, while hundreds more will be in a similar condition in a year or two after leaving school "[4] And efforts at prevention are not always rational when, as Toller ruefully observes,[5] films directed at the iniquity of eating the wrong foods between meals are shown to schoolchildren on projectors bought out of the profits of the school tuck-shop

On the pathology, Darling[6] makes it clear that, despite a fair amount of agreement about many of the processes in the development of caries, we do not fully understand what takes place and the reasons It is a tribute to W D Miller that his " chemicoparasitic " hypothesis, first described in 1890,[7] is still accepted with slight modifications that concern mainly the role of the dental micro-structure There can be little doubt that caries is predominantly a local process although systemic factors can affect the tooth structure during development, they are not likely to produce any change in the enamel after eruption Similarly, while the composition of the saliva may have some slight effect on the process of decay, it is unlikely to exert more than a modifying influence Caries originates in the bacterial fermentation of refined carbohydrates retained in stagnation areas around the teeth, and this fermentation produces some agent that attacks the enamel What this agent is has not been determined—it could be an acid, a substance causing proteolysis, or a chelating agent A proteolytic substance seems to be the least likely of the three, since proteolysis has not been demonstrated until fairly late in the carious process There is, however, a good deal of evidence that lactic acid may be responsible Lactic acid is found in stagnation areas, carious enamel contains an abnormal amount of lactate, dilute lactic acid will produce lesions resembling those of natural caries, and lactic acid can act as chelating agent

Dental caries is a complex process—rather is it a chain of processes determined by several factors In theory the elimination of one of these factors should interrupt the sequence, but in practice no one method has prevented caries completely The great significance of the accumulation of refined carbohydrates in the stagnation areas around the teeth has been shown by Gustafsson et al in Sweden[8] The oft-expressed opinion that one specific organism is responsible for carbohydrate fermentation in the mouth seems to be untenable (and certainly this did not form a part of Miller's original hypothesis) *Lactobacillus acidophilus* is found in association with caries, but the disease has been produced artificially both with a streptococcus and with an enterococcus The importance of the structure of the tooth was almost neglected until the publication in 1934 of the work of Mellanby,[9] which showed a connection between minor enamel hypoplasia and the incidence of caries The structure of enamel is still imperfectly understood, but it exerts a great influence on the development of caries Properly developed enamel has a highly resistant surface zone, some 30 μ thick[10]—which is important in prevention, since this zone may easily be abraded during conservative treatment of adjoining teeth

Caries in the enamel progresses by selective decalcification, certain parts of the micro-structure being attacked first, and at present the only reasonable explanation seems to be that this is associated with the distribution of soluble and insoluble proteins in the enamel About equal amounts of each type of protein are present in the interprismatic spaces,[11] and the soluble protein is assumed to be the first part of the tooth substance to disappear The situation is now complicated by the work of Helmcke,[12] which suggests that the interprismatic spaces may be optical illusions From electron microscopy of enamel he concludes that these spaces are produced by the refraction of light along the optic axes of the hydroxyapatite crystals forming the prisms Since it is highly improbable that these axes would all be parallel, the resulting system of optical lenses could produce—in a light microscope—the appearance of dark areas which do not in reality exist

To quote Professor Darling " If we are to prevent caries we must seek to break the chain of processes which cause the lesion " Of the various means available to the dentist, none is wholly effective Stagnation of food around the teeth can be reduced, but not eliminated, by intelligent and efficient brushing To induce patients to reduce their intake of refined carbohydrate is very difficult, but something can be achieved by limiting the intake of carbohydrates strictly to mealtimes, and to the half-hour immediately afterwards, provided this is followed by attention to oral hygiene Antiseptics can render the mouth almost sterile for short periods, but are soon dispersed and diluted by the saliva Artificial immunity has been produced but is only ephemeral Enzyme inhibitors have been tried,[13] apparently with some initial success, but little has been heard of them in the past decade A more promising, though empirical, method is the administration of pyridoxone (vitamin B_6)[14], but this has not yet been established as a practical means of control The neutralisation of lactic acid as it is formed presents the same difficulties as in making the oral cavity sterile it is almost impossible to modify the composition of the saliva Rendering the soluble protein of the enamel insoluble might prevent a great deal of caries—a possibility which is now being investigated The use of silver nitrate has little scientific backing, and yet clinical experience shows that it is often effective

But neither the ramifications of research nor the skilful expedients of dentistry should distract attention from the most important fact about caries—that it is a consequence of malnutrition and that we already know enough to prevent nearly all of it In his fascinating review of the changes in its incidence and distribution in this country throughout the ages, HARDWICK[15] relates these to changes in our diet, which have been greater in the past hundred and fifty years than ever before When a disease goes up and down with alterations in feeding, it is obviously a soluble problem of public health, and, though HARDWICK is not prepared to say which of the many nutritional alterations of the 19th and 20th centuries is chiefly responsible for caries, he shows that all the more likely factors are related to refining of foods Most conspicuous, perhaps, is the loss of most of the components which promote mastication and natural cleansing of the teeth Next there is the large consumption of refined sugars, which (together with heating of our homes and lessening of our physical activity) has reduced the intake of old-fashioned foods containing possibly protective factors such as vitamins and trace elements Likewise the concomitant modifications of the processing of flour " have been followed by marked changes in caries activity " Changes in the incidence of the disease during and after the two world wars suggest that there are (or should be) factors in food whose absence during a tooth's formation makes it susceptible to caries later " An increasingly large group of research workers believes that these protective factors are of an inorganic nature and it has been suggested that caries may be a trace element deficiency disease "

The day may be far distant when the public can be weaned from its present somewhat infantile overdependence on refined sugar and fat indeed there are hardly any signs yet that doctors and dentists care enough about nutrition to set their weight firmly against the commercial interests concerned Meanwhile, though perhaps a pis-aller, the correction of fluorine deficiency seems to be our most hopeful objective Where water-supplies are clearly below normal in fluorine content, any reasonable person should be willing to accept the minute addition of fluoride needed to make up for the geological lack Doing no more than this has sometimes reduced the local incidence of caries by as much as half

FERTILITY CONTROL

IF man's most pressing task is to escape total destruction by nuclear warfare, the next most urgent is to feed and clothe his ever-increasing family[1] Economists since the days of Malthus have insisted that measures to increase food production are bound to prove increasingly ineffective as time passes Fertility, according to this viewpoint, must be controlled, though without prejudicing the health and welfare of the individual or the race This simply stated goal is proving difficult to attain—a fact that testifies to the long course of evolution in which mammals have been developing means for protecting sex cells and embryos from environmental interference

Reproduction can be blocked in broadly two ways by preventing the production and union of sex cells, and by bringing about, directly or indirectly, the death of the embryo It is now agreed that ideally contraception should be applied by oral administration of the active agent, and specifications for an ideal contraceptive have been drawn up[2] Some of the latest products of the search for a suitable agent were discussed by Dr H Jackson in an address to the Pharmaceutical Society on Dec 3

Dr Jackson is well known for his studies on several groups of organic compounds, notably the ethyleneimino derivatives, one of which is tretamine (T E M) Administered in a single moderate dose to male rats, this damages the late spermatids but not the earlier spermatogenic cells nor the maturing spermatozoa As a result, the rats become sterile between the 20th and the 26th days after treatment, though they are fertile before and after this period At higher dose levels, the damage extends to other stages of spermatogenesis, involving spermatogonia and maturing spermatozoa[3–5] Similar results have been obtained with mice[6] The action of tretamine, besides being remarkably cell-specific, is notable in that it renders the epididymal spermatozoa infertile without inhibiting their motility or their ability to reach and enter the eggs

Another group of compounds discussed by Dr Jackson was the sulphonoxalkanes, such as busulphan (' Myleran ') Here again, damage tends to be concentrated at specific stages of spermatogenesis with busulphan on the spermatogonia, with chloroethylmethanesulphonate on the spermatids and spermatozoa, and with dimethylmyleran on both groups of cells[4] With these and other compounds of the same family, it is evidently possible to build up a " spectrum " of activity, wherein variations in effect accompany relatively small differences in chemical structure These drugs can yield precise data on the course of spermatogenesis and on the physiological and chemical peculiarities of the spermatozoon But whether they can suitably be applied to the control of fertility in man is another matter, for they are known to be capable of producing changes in the genetic material of the spermatozoon,[6,7] and for other reasons, too, may be classed as radiomimetic agents[8] Substances which have these effects, but which do not prevent the spermatozoon from entering the egg, cannot be regarded as any less hazardous than atomic radiation and should be treated with the same reverence

Dangers of somewhat lower degree, though still serious, attend practices that depend on destruction of the early embryo Here, too, phenomenal specificity of chemical action is manifest, notably in the lethal effect of the triphenylethanol derivative known briefly as MER-25 on the unimplanted embryo[9] and that of podophyllotoxin after implantation[10] This work represents a fascinating aspect of experimental biology, but there is an ever-present risk that the embryos may not all be killed and that damaged embryos may survive to term

Some lines of research seem to offer hopes of satisfactory results with comparative safety these depend on suppression of ovulation or of implantation The best known is the oral administration of certain 19-nor steroids with progestational activity which apparently inhibit the gonadotrophin output from the pituitary[11] Hopeful also are the results with *m*-xylohydroquinone[12,13], this substance is believed to inactivate gonadotrophin, œstrogen, and progesterone in vivo by combining directly with them In the suppression of implantation, some success has been reported in rats treated with ergotoxine,[14] but the most innocuous method of achieving this effect has recently been observed in mice pregnancy was interrupted at high frequency by no more drastic an expedient than allowing the females to become aware of the proximity of strange males[15,16]

TREATMENT OF INFECTIONS IN HOSPITAL

IN the past twenty-five years sulphonamides, penicillin, antituberculous drugs, broad-spectrum antibiotics, various antistaphylococcal agents, and some promising antifungal substances have become available Nevertheless, infective disease remains undefeated and some types are on the increase The lamentable lack of achievement has been exposed by Finland and his colleagues[17] in an authoritative report to the Council on Drugs of the American Medical Association These workers have reviewed the changing pattern of infections observed in the Boston City Hospital in certain years, carefully chosen to reflect the changing fashion in chemotherapy The year 1935 was selected as a baseline for the pre-sulphonamide era, 1941 to reveal the impact of the sulphonamides before they had been joined by penicillin, 1947 when both penicillin and streptomycin had been widely used, 1951 to show the influence of the broad-spectrum antibiotics, and 1957 to define recent trends influenced by most or all currently available antibiotics In order to make valid comparisons, attention was restricted to septicæmia, meningitis, empyema, and necropsy material from which bacteriological studies were satisfactory

In 1935 about 300 septicæmic patients were admitted to hospital and roughly three-fifths of these died By 1957 there were twice as many septicæmic patients, nearly two-fifths of whom died whereas 2 out of 5 septicæmic patients could be saved in the dark ages before sulphonamides, no more than 3 out of 5 survive with the help of modern chemotherapy The decline in mortality occurred in the years 1935–41, when the sulphonamides were in exclusive use, for by 1941 only one-third of septicæmic patients died Since then and, with the use of penicillin, streptomycin, and the broad-spectrum antibiotics, the mortality-rate has increased

In contrast, meningitis and empyema have become rather less of a challenge As regards meningitis, there were rather more cases in 1957 than in 1935, but between these years the mortality had steadily fallen from 80% to 20% Between these particular years the number of patients with empyema had halved, although the mortality rate had risen slightly from 20 to 30%

The bacteria isolated from these infections have changed significantly over the years, and this changing flora mirrors the success and failure of the antibiotics Pneumococci and hæmolytic streptococci have continued to remain sensitive to antibiotics, but success in this direction has been offset by the increasing incidence of infection due to staphylococci, enterococci, and various gram-negative organisms, against which existing drugs are less potent. The mortality-rate of septicæmia due to gram-positive organisms was 67% in 1935 and 33% in 1957 The fall in mortality would have been far more impressive but for staphylococcal infections, whose incidence quadrupled over these years The incidence of septicæmia due to gram-negative organisms increased sixfold, and the mortality also rose slightly from 42% (1935) to 54% (1957) In essence, the antibiotic era has witnessed a change from pneumococcal to staphylococcal and coliform septicæmia The gravity of the staphylococcal menace is reflected also in the frequency with which this organism was isolated in pure or almost pure culture from one or more important sites in necropsy material It was recovered from 7% of necropsies in 1935 compared with 24% in 1957 Finland and his coworkers draw attention to this as a crude index of the increasing significance of *Staphylococcus aureus* as a cause of death

This survey might be interpreted less confidently had it not been made at the Boston City Hospital—a large general city hospital, admitting 4 patients every hour round the clock, where throughout the years covered by the survey Dr Maxwell Finland has himself been responsible for the management of infections

Possible steps to reduce the hazard of infections include vigilance against cross-infection, combination of antibiotics, rotation of drugs, limitation of the use of some, the introduction of fresh antistaphylococcal agents, and new measures to improve host resistance That the challenge has been accepted in London is evident from the painstaking work of Barber and her colleagues[18] and the cooperation of the whole staff of Hammersmith Hospital, where some reversal of antibiotic resistance in hospital staphylococcal infection has already been achieved by the introduction of some of these measures in the surgical wards At the beginning of the investigation, 70% of staphylococcal infections were resistant to penicillin and tetracycline and only 12% were sensitive

to penicillin At the end of the investigation, 36% of the infections were resistant to penicillin and tetracycline and 48% were sensitive to penicillin The use of penicillin was deliberately restricted, and broad-spectrum antibiotics in combination were used more freely The consumption of penicillin in the hospital was halved, but that of tetracycline, chloramphenicol, and erythromycin doubled, and the use of novobiocin increased sixfold The increased cost entailed by this programme is unimportant if it succeeds One peril is that gram-negative organisms may become increasingly often resistant to the broad-spectrum antibiotics It would be difficult to defend the unlimited use of polymyxin for bacillary dysentery and trivial skin infections in a hospital, if this involved an increase in infections with resistant pseudomonas for which originally only polymyxin is effective This organism alone was responsible for 13 deaths in 1957 in the Boston City Hospital, compared with none in 1935 Barber and her coworkers are well aware of this danger, and, in re-shaping their policy for the next phase of the attack on hospital infection, they might even include the coliform organisms with staphylococci as their quarry

CLASSIFICATION OF PSYCHIATRIC DISORDERS

DISCOVERING the prevalence of mental disorders in different communities helps both to throw light on their causation and to plan the therapeutic services Minor psychiatric illness is much commoner than is usually realised, both as "maladjustment" in children [1] and in adults consulting their family doctors [2], and outpatient facilities must be planned to meet the need Arentsen and Stromgren [3] have reported a survey based on a census of all persons resident in Danish psychiatric institutions on a day in the autumn of 1957 The prevalence of such patients—228 per 100,000—was considerably less than the 342 per 100,000 in this country and the 430 per 100,000 in Sweden, and this was presumed to be due to nosocomial factors rather than to differences in morbidity Sweden has been able to provide more hospital beds than Denmark and Norway (where the rate is also low), and geographical factors make outpatient management easier in Denmark Distribution of diagnostic subgroups did not, overall, differ greatly throughout the country, but diagnostic practices in certain hospitals were strikingly discrepant, reflecting the present unsatisfactory state of classification In her survey of mental illness in London, Vera Norris [4] found similar differences In some conditions the concordance of diagnosis for the same patient between observation ward and mental hospital was less than 30% Agreement on schizophrenia and manic-depressive psychosis, however, was about 70%, and the difference between the diagnoses was borne out by the very highly significant ($P < 0\ 0001$) differences in duration of stay Prof Erwin Stengel [5] has surveyed 58 current classifications at the request of the World Health Organisation He found that none was wholly satisfactory and most were bedevilled by national and personal sentiment Despite minor difficulties with cardiovascular classification [6] the International Classification of Diseases has been generally accepted throughout the world except for the psychiatric section Disagreement on definition has led to gross discrepancies in use, and Professor Stengel maintains that an acceptable classification demands that grouping be exhaustive and the categories mutually exclusive with each explicitly defined That the present system has failed is made clear by Miss Eileen Brooke [5] The I C D and the American Psychiatric Association classifications are theoretically interchangeable, but when some 200 diagnoses were coded on each separately and the A P A coding was used to give an I C D code number, there was concordance in only a minority Cohort analysis of cases discharged and readmitted elsewhere within four years showed a similar minority of concordant diagnoses Miss Brooke concluded—as did Dr Norris from similar findings—that only with the broad groupings did diagnosis seem "not completely haphazard"

This unsatisfactory situation is hindering progress [7] Pending the evolution of objective indices, we can only await the outcome of W H O 's endeavours and hope that the conclusions will prove universally acceptable Fortunately the planning of our future services need not wait on these deliberations, Professor McKeown and his colleagues, for example, have described a very useful system of classification, based on the treatment needs of patients, which ignores diagnosis [8, 9]

PULMONARY ARTERIOVENOUS FISTULA IN HEREDITARY HÆMORRHAGIC TELANGIECTASIA

EVERY large general hospital is certain to have on its list of frequent attenders a small group of unfortunate adults who come to the casualty department complaining of recurrent bleeding from the nose or lips or mouth The blood is seen to stem from an insignificant leak in the centre of a small ruby patch, many of which are usually to be found scattered here and there on the mucous membrane Although the flow of blood is seldom vigorous it may eventually, by its persistence, cause some concern Its arrest can certainly be infuriatingly difficult, whether it be attempted by sustained compression or by cautery, or by both Each ruby patch marks the position of a tiny arteriovenous communication at the capillary level Presumably these vessels are very close to the surface, or else they are abnormally fragile Whatever the cause, they can be induced to bleed by the most trivial of injuries

This vascular anomaly is not restricted to the mouth and nose, but may affect any portion of the skin of the trunk Similar lesions can also involve mucous membrane elsewhere, and bleeding from the gastrointestinal tract or hæmaturia often feature in the history The disease is known to be hereditary and is presumed to be transmitted as a simple dominant with equal frequency by males and females Most have now agreed to call the disease hereditary hæmorrhagic telangiectasia, but some students and compilers of texts still delight in the eponymous prolixity of Rendu-Osler-Weber disease

Arteriovenous shunts in the lesser circulation, between branches of the pulmonary artery and of the pulmonary vein, were recognised at necropsy at the turn of the century, but it was not until 1939 that the first case was diagnosed clinically [10] The triad of cyanosis, polycythæmia, and clubbing, which are the clinical features of the more serious shunts, is now widely recognised. Only in more recent years has it been widely appreciated that the great majority of patients with pulmonary arteriovenous fistulas will be found on careful examination to have, in addition, the characteristic lesions of hæmorrhagic telangiectasia. Purnel and Muras[11] in an analysis of 170 reported cases found that, of 102 patients concerning whom full information was available, 70 had cutaneous telangiectasia and that in close on 60% there was a family history of the disease. It seems clear, therefore, that we must now regard pulmonary arteriovenous fistulas not as localised lesions but as part of a general vascular anomaly, and that we must for this reason seek out other vascular deficiencies in seeking supporting evidence of a pulmonary arteriovenous shunt.

How many patients who present with evidence of hæmorrhagic telangiectasia have, in addition, pulmonary arteriovenous fistulas? Clagett et al.[12] have now partly answered this question. They studied 330 descendants of a young man who migrated from Germany to the United States in the '60s or '70s of last century, and who passed on the stigmata of hæmorrhagic telangiectasia to the generations that followed. It must be a close-knit family, for no fewer than 231 of them could be traced, and of this number 40% were found to have overt manifestations of the disease. When the investigation was narrowed down in a search for pulmonary arteriovenous fistulas, these were found to be present in 14 (i.e., 6·1% of the family group studied). In 8 it was found in a routine X-ray, in 6 there were symptoms and signs attributable to the bypass.

The finding of fistulas in such a high proportion of cases suggests that we should review from time to time all adult patients with hæmorrhagic telangiectasia, for the hazards of an uncorrected fistula can be formidable, including hæmothorax, thrombosis, and cerebral abscess. Whether we stumble on this lesion or unearth it only after diligent inquiry, its operative correction in every case may not be justified. The fistulas are often multiple, and it is important not to destroy too much healthy lung tissue. The need for operation will be determined by the number of fistulas and by their size and location.

BLOOD SAMPLES

BLOOD taken for the Wassermann reaction has proved useful for purposes besides the diagnosis of syphilis. Quite frequently a pathologist who has wished to establish normal values for some biochemical estimation, or to look for antibodies to some infection in the general population, has found his evidence in the sera left over from the W.R. Similar use has been made of blood taken for grouping or for biochemical tests. Such specimens have yielded some useful information but are far from perfect. In this country at any rate, those suspected of having syphilis are not a fair sample of the population, and those whose blood is sent to the biochemist will presumably be ill. Blood donors will be healthy, but there will be no children in the sample and the Registrar General's classes I and II will be over-represented. To obtain a random sample fortuitously is, in fact, almost impossible. Another difficulty with samples obtained by chance is the absence of useful information to accompany them: the discovery of brucella antibodies is almost meaningless without knowledge of the residence and occupation of the subjects.

As an improvement on the use of surplus blood specimens there is a lot to be said for the deliberate survey. The subjects can be chosen and classified on the spot. The serologist or biochemist (but rarely the hæmatologist) can collect his specimens in remote and barbarous places and examine them at leisure in a well-equipped laboratory. Such surveys have already given useful results on many subjects—for instance, the distribution of antibodies to poliomyelitis and the frequency of leptospiral infections in dogs. A publication from W.H.O.[1] contains some excellent advice and suggestions.

The simplest example is the establishment of a "normal" value in a static community, but the experimenter will soon find that, though the "normal" is a common animal, it is very hard to catch. Medical students and nurses are traditional normals but they represent limited age and social groups and are (or should be) the thing most hateful to the statistician—volunteers. The inmates of mental hospitals and gaols are less representative of the community as a whole than might be imagined. The most satisfactory sample among young adults is probably obtained from conscripted recruits to the armed services. It seems that less sophisticated communities are sometimes easier to sample. One of the most profitable uses of the survey method has been in the detection of influenzal antibodies in isolated villages. To judge from the published accounts the Eskimo in Greenland is far more generous with his blood than the English rustic. The success of the detailed surveys by the M.R.C. Pneumoconiosis Unit in the Rhondda Fach and elsewhere shows what sincerity and enthusiasm can do, but to obtain quite a small blood sample from a cross-section of the whole population of, say, Bournemouth would be difficult and time-consuming. Electoral rolls, school registers, and registrations of births allow the investigator to select a random sample within a limited age-group with precision, though he is likely to lose up to 20% owing to natural movements of the population. Persuading the subjects (and their mothers) to allow venepuncture is another matter: at no age is it painless or without risk of minor damage. The appeal for the general good which goes for little in the population as a whole can be a powerful weapon in a group of skilled tradesmen or an army unit. Persuasion gets a little attention in this booklet. It is a subject on which the serologist might be wise to consult the psychologist.

Samples of serum can be kept for years by freezing, and W.H.O. envisages a serum bank for use by investigators in the future. The idea is attractive and has already been put into action in a small way here and in the U.S.A., but we fear that its application may lead to some disappointments. Asking the right question at the right time is difficult enough, but to ask the questions which will be right in ten years' time will be a near-miracle. Multipurpose blood surveys are more promising, but without doubt those which have been most productive in the past have been those with limited objectives—e.g., the search for yellow-fever antibodies in Central Africa. But such surveys are neither cheap nor easy and they cause bother and discomfort to many, and anyone who undertakes them should have a clear conscience that what he does is for the general weal.

In a number of recent reports the distribution of marrow chromosome counts have been recorded from both normal and abnormal individuals

The technique of making the bone-marrow preparations has been described by Ford, Jacobs, and Lajtha (1958), the basic steps being the short-term culture of the marrow cells in the presence of colchicine, the treatment of the cells with a hypotonic solution, and their subsequent squashing under a coverslip The chromosomes are then counted in suitable cells—i e, cells in which the chromosomes are well spread and lie as far as possible in the same optical plane It is unusual, however, for every metaphase cell selected for counting to show the same number of chromosomes, and a range of chromosome counts is recorded in which the majority of atypical cells have a chromosome number less than the modal number

In selecting cells for counting, cells considered unsuitable are those in which the chromosomes are poorly spread, those in which it is obvious that the cell has been ruptured and chromosomes lost, and those in which the appearances of the chromosomes indicate that one or more have been split at their centromeres into their sister chromatids It is possible to ensure that in selected cells there are no chromosomes that have been obviously split at their centromeres, but it is not possible, in selecting cells for counting, to be certain that one or two of the chromosomes have not been lost

In preparations made from bone-marrow in which there are no malignant cells it is customary to accept the modal number as the true somatic number of the individual and to regard counts differing from this as due to the presence of artefacts It is possible, however, that in a normal bone-marrow there may be occasional cells with a true chromosome number different from the modal number, and it is also possible that an occasional individual may be a mosaic—i e, his body may contain two or more stem lines with different chromosome numbers Several such presumed mosaics have been reported by Ford and his coworkers (Ford et al 1959, Ford 1959a), —i e, an XX/XXY mosaic containing cells with 46 and 47 chromosomes, and three XO/XX mosaics with cells having 45 and 46 chromosomes

Our object here is to discuss (1) the meaning of the variability of chromosome counts, and (2) the conditions to be fulfilled before a presumed mosaic can be accepted as a reality Our assessment can be no more than preliminary, since the techniques are new and the preparative standards have changed appreciably over a short period, but a review seems desirable because the significance of the reported variations in chromosome number has been misunderstood

For example, Ford, Jacobs, and Lajtha (1958) recorded a case of pernicious anæmia in which 25 out of 70 cells examined showed chromosome counts less than the modal number of 46, and it has been inferred from this by others that true numerical chromosome abnormalities may occur in the bone-marrow of patients with pernicious anæmia (*Lancet* 1959) Subsequently Ford (1959b) pointed out that this particular marrow preparation was made at a comparatively early stage in the development of the technique, and that the variation in chromosome number was most likely to have been due to preparative faults The data from five untreated cases of megaloblastic anæmia which we give below support his conclusion, and on present evidence there appears no reason to doubt that such patients have a normal diploid number of 46

Material

The marrow chromosome counts have been analysed from fifty-seven patients and ten healthy subjects in whom the modal number was 46, four with a modal number of 45, and thirteen with a modal number of 47 The material was obtained from the following groups

Modal Number 46

A Ten healthy males and females Several of these were studied because their children had shown chromosomal abnormalities

B Four patients with testicular feminisation Data for these have been published by Jacobs et al (1959a)

C Fourteen patients with ankylosing spondylitis

D Six patients with testicular cancer, in none of whom was there any evidence of metastatic spread

E Seven patients with male gonadal dysgenesis in whom the nuclear sex was male

F Five patients with primary amenorrhœa

G Five patients with untreated megaloblastic anæmia

H Nine patients with various congenital or genetically determined conditions

I Seven patients with various other conditions

Modal Number 45

J Four patients with Turner's syndrome—i e, female gonadal dysgenesis with a male nuclear sex and a chromosomal sex of XO The data for one of these (H188) have been published by Jacobs and Keay (1959)

Modal Number 47

K Nine patients with mongolism, the data for four of whom (H114, H120, H122, H125) have been published by Jacobs et al (1959b)

L Three patients with Klinefelter's syndrome—i e, male gonadal dysgenesis with a female nuclear sex and a chromosomal sex of XXY The data for one of these (H54) have been published by Jacobs and Strong (1959)

M One patient with a female nuclear sex and a chromosomal sex of XXX—the "super-female" described by Jacobs et al (1959c)

It will be noted that in the descriptions of the eleven cases which have been published previously, the chromosome counts relate in each instance to a larger number of dividing cells than those given in the present tables The reason is that our practice has been to score the counted cells in two ways, distinguishing the results for those cells for which there have been no doubt about the counts from those cells for which the exact number of chromosomes is uncertain In these latter a decision was made as to which category of chromosome number each cell was most likely to belong to, and, in the previously reported counts, both the certain and the uncertain cells have been included In this and subsequent communications unless otherwise stated, we shall report cells only when an exact count can be made

Results

The data for patients with a normal chromosome number are given in table I, the numbers of cells which contained less than 44, 44, 45, 46, 47, 48, and more than 48 chromosomes are shown separately Polyploid cells were seen in many of the preparations, but these cells have been excluded because the standards required to recognise a polyploid cell are less strict than those required to determine the exact number of chromosomes in a diploid cell The proportion of polyploid cells recorded in a count is therefore likely to be misleading, unless it is sought as a separate item.

The total number of cells in each category has been summed for each group of conditions in table I, and the grand totals have been determined for sixty-seven subjects. Altogether 1602 cells have been counted, of these 1362

* (−ve) and (+ve) indicates male and female nuclear sex.

† H161. This patient presented with short stature, webbing of neck, unusual thickening of the occiput, a high arched palate, myopia, and strabismus. He was originally thought to be perhaps a male example of Turner's syndrome.

‡ See footnote, p. 162.

TABLE II—PROBABILITY OF OBTAINING THE OBSERVED PROPORTIONS OF TYPICAL AND ATYPICAL CELLS IN NINE GROUPS OF PATIENTS WITH NORMAL KARYOTYPES

Group (no. of subjects)	Value of χ^2	Probability (n = 1)
A Healthy men and women (10)	0·150	Between 0·1 and 0·9
B Testicular feminisation (1)	0·001	0·97
C Ankylosing spondylitis (14)	0·012	0·91
D Testicular cancer (6)	0·110	Between 0·1 and 0·9
E Chromatin negative male gonadal dysgenesis (7)	4·200	0·04
F Primary amenorrhœa (5)	0·230	Between 0·1 and 0·9
G Untreated megaloblastic anæmia (5)	0·920	" "
H Various congenital or genetically determined conditions (9)	1·447	" "
I Various other conditions (7)	1·817	" "

(85·0%) contained 46 chromosomes. Examination of the distribution of cell counts shows that the distribution is not symmetrical but is negatively skewed, and that 12·1% of cells give counts of less than 46 in contrast to 2·9% with counts in excess of 46. This greater preponderance of "atypical" cells with counts of less than 46 chromosomes is seen in all the groups and, in each of them, the most common type is a cell with a count of 45 chromosomes.

The homogeneity of the material shown in table I may be tested by comparing separately the data for each group of patients with those obtained from all the groups together. The results (table II) show that the variation in the proportion of atypical cells in each group can reasonably be attributed to chance. The most extreme variation (group E) would be expected to occur once in 25 tests. This figure must be interpreted in the light of the fact that nine groups were examined and it is reasonable to suppose that among so many groups a probability of this order would occur at least once due to chance factors alone (P = 0·44).

A more detailed analysis has also been made by examining for each patient the probability of obtaining the observed proportion of cells with modal and non-modal counts. These have been obtained from published Binomial Tables by assuming that the expected proportion of cells with non-modal counts was 15%.* The distribution of the individual probabilities is shown in table III. From the table it appears that there is a tendency to record counts with the more extreme probabilities, but, with the present number of observations, we cannot be sure that this is not a chance finding ($\chi^2 = 11{\cdot}66$, n = 9, $0{\cdot}2 < P < 0{\cdot}3$). The most extreme probability recorded was in case H115 (a man with idiopathic acquired hæmolytic anæmia), in this subject 8 of 29 cells counted showed 45 or less chromosomes and 3 cells showed 47 chromosomes. The probability of recording so many or more atypical cells is estimated at about 0·001. In our series of sixty-seven patients one probability of this order can be expected, by mere chance, slightly *more often than once in 20 times (P = 0·06). It may be noted,* however, that in this extreme case, the marrow preparation was regarded as technically poor before the count was made, and the whole preparation may well have contained more than the usual proportion of artefacts.

TABLE IV—CHROMOSOME COUNTS IN FOUR PERSONS WITH A MODAL NUMBER OF 45

Total all groups			7	13	29	305	11	5		370	

Difference between proportions of atypical cells, patients with modal number of (*a*) 46 and (*b*) 47

$\chi^2 = 1{\cdot}538$, n = 1, $0{\cdot}2 < P < 0{\cdot}3$

The data for patients whose cells show abnormal numbers of chromosomes are summarised in table IV (modal number 45) and in table V (modal number 47). In both the proportion of atypical cells is slightly greater than that recorded for subjects with a normal modal number of 46—i.e., 19·5% and 17·6% atypical counts compared with 15·0%. In neither is the difference significant, but the number of patients examined is still small and, if the expected proportion of non-modal counts was 15%, there were two patients (H 98 with Turner's syndrome, and H 127 with mongolism) with a type of count which would be expected to occur less often than once in 100 times. On the basis of these data, it seems wise to suspend judgment about whether the cells of patients with an abnormal karyotype may also show abnormal variability in the number of their chromosomes.

Discussion

In reporting the distribution of chromosome counts it has generally been accepted that the modal number represents the true somatic number, and that deviations from it are due to preparative faults. One may reasonably suppose, however, that mitotic errors occasionally occur in somatic tissues and give rise to cells with chromo-

TABLE III—PROBABILITY OF OBTAINING THE OBSERVED PROPORTION OF TYPICAL AND ATYPICAL CELLS COMPARISON OF OBSERVED AND EXPECTED DISTRIBUTION (67 SUBJECTS WITH NORMAL KARYOTYPE)

---

* Since it was desired to examine the distribution of probabilities, the figure given is the probability of obtaining more than the observed number of non-modal cells plus half the probability of obtaining the number actually observed. This overcomes the difficulty resulting from the fact that the variable concerned is discontinuous. The mathematical justification for this technique is discussed by Lancaster (1949).

some numbers different from the modal number These errors are presumably due to non-disjunction, and are comparable to those that occur during parental gametogenesis In the latter case the affected gametes give rise to monosomic or trisomic individuals, so far represented in man by the clinical conditions of Turner's syndrome, Klinefelter's syndrome, mongolism, and the "superfemale" Ford and his colleagues have advanced the general argument that if a non-disjunctional error causes the loss of the Y chromosome in some of the cells of an XXY zygote, producing normal XX cells, and if normality offers some selective advantage over the cells with the abnormal trisomic condition, then a mosaic state could arise. Mosaicism could also be the result of a non-disjunctional error at an early stage in the development of a normally constituted zygote, one of the resultant abnormal cells dying and the other persisting to give rise to a clone of cells with an abnormal chromosome number

There are, therefore, three possible reasons for the observed variation in marrow chromosome counts (1) artefacts, (2) mitotic abnormalities, and (3) mosaicism

In performing chromosome counts particular attention is paid to the cells in which the count differs from the modal number In our opinion the great majority of such cells arise during preparation, the most common fault being the rupture of the cell with the loss of one or more chromosomes Detailed study of the cells containing one chromosome more than the modal number reveals no evidence of an artefact, but there are reasons for thinking that the count is genuine in only a minority In the others the atypical count is due either to unrecognised splitting at the centromeres (the sister-chromatids being widely separated and enumerated as two chromosomes) or to the inclusion of a chromosome from a neighbouring cell If some of the cells with excess chromosomes are genuine there are also likely to be a few cells with true counts less than the modal number, though these cannot be distinguished from cells which have lost a chromosome or chromosomes through cell rupture The data from individuals with a normal karyotype (table I) show that less than 3% of cells have counts above the modal number Even if all these represented genuine aberrations from the modal number (which is very unlikely) and there was an equal proportion of cells with a true count less than the modal number, it would still follow that the majority of atypical cells were artefacts

In view of the variability of the counts in normal individuals it is clearly difficult to prove that a particular count indicates a mosaic In our opinion three criteria need to be fulfilled before the diagnosis can be established

1 The number of cells with counts different from the modal number must be more than can reasonably be attributed to chance (As more subjects are examined, more extreme variations are certain to be observed due to chance alone)

2 The excess of atypical cells must be demonstrable in two or more separate bone-marrow examinations and preferably in two or more tissues A suitable technique has been evolved for the study of chromosomes in the culture of skin (Harnden 1959), but a negative result from skin culture may not contradict the findings from marrow cultures, as two cell lines may be freely mixed within the marrow but occupy topologically distinct areas of skin, or mosaicism may be confined to the bone-marrow and not involve other tissues

3 A detailed analysis of the chromosomes in cells containing more or less chromosomes than the modal number must provide evidence that a high proportion of such cells have the same karyotype—i e, that the additional or the missing chromosomes are the same ones in different cells

The proportion of atypical cells reported by Ford and his coworkers in four patients (one presumptive XX/XXY mosaic, and three presumptive XO/XX mosaics) is much higher than could reasonably be attributed to chance on the basis of our experience It is, however, unsatisfactory to use data compiled by one group to test the significance of data collected by others and, so far as our own data are concerned, there is no reason to postulate the occurrence of a mosaic among the first eighty-four subjects to be examined

Summary

The distribution of chromosome counts has been analysed from the bone-marrow preparations of sixty-seven people who have shown an apparently normal karytope

The distribution is negatively skewed around the modal number of 46, 85% of the cells showing a count of 46 and approximately 12% a count less than 46 Of the latter more than half showed a count of 45 chromosomes The reasons for this type of distribution are discussed

The chromosome counts in four people with a modal number of 45 and in thirteen with a modal number of 47 have also been studied While the number of such persons is small the indications are that no unusual distribution of counts occurs, although more data are required for a final conclusion

Certain criteria are suggested, which ought to be satisfied before a diagnosis of a chromosomal mosaic involving two or more cell lines can be substantiated

CASUALTIES AND CASUALS

LIONEL FRY
M B, B Sc Lond
FORMERLY CASUALTY OFFICER, KING S COLLEGE HOSPITAL, LONDON, S E 5

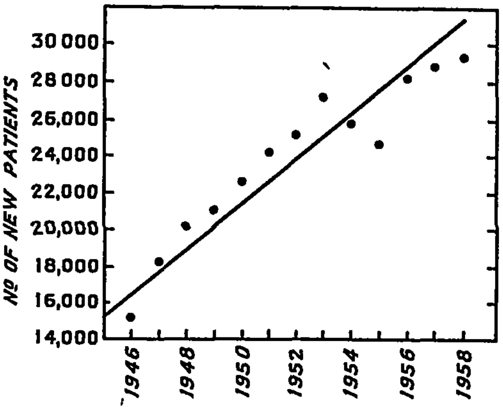
THOUGH within the bounds of the hospital, the casualty department is an entity of its own, usually staffed by junior doctors with a very brief term of service Papers have been written and suggestions made on how it should be planned (Clarkson 1956, Lowden 1956, Bowen 1957, Hilzinger and McAllister 1957, Shortcliffe 1958) but little is known about the character, incidence, and disposal of the cases seen in it The only previous analysis known to me was confined to medical patients (Mestitz 1957)

I record here my experience of 5000 attendances seen by me consecutively in the casualty department of a London teaching hospital, between July and December, 1958

The Department

The hospital is in south-east London, in a densely populated area Most of the people belong to the lower social classes, and there are about 25,000 Jamaicans in the neighbourhood

The department has a medical staff of five Two are post-registration appointments, and three are pre-regis-



Increase of new patients attending casualty department

tration Two of the pre-registration housemen work also in other departments of the hospital The casualty officers are ultimately responsible to a consultant surgeon at the hospital

Patients can be admitted under the casualty officer for up to forty-eight hours (after which they must be referred to the appropriate department), or they can be referred direct to a consultant Referral from casualty to the outpatient department is by the usual method All fractures are seen next day in the casualty fracture clinic, which is the responsibility of the orthopædic department

The continuing increase in the number of new patients is shown in the figure

Reattendances in the department (at the doctor's request) tend to rise when a new set of casualty officers take up their posts, or when locums are employed Requests for reattendance also vary with the individual doctor In my personal series there were 2935 new patients (60%) and 2065 reattendances (40%)

The Series

The age-distribution of the 5000 patients is shown in table I

TABLE I—AGE-DISTRIBUTION

0–9	10–19	20–29	30–39	40–49	50–59	60–69	70+
799	1060	985	765	641	342	178	230
16%	21%	20%	15%	13%	7%	3 5%	4 5%

There was a male preponderance of 3 to 1 (3680 males and 1320 females)

The sources of the new patients were

Casuals (patient comes on own initiative)	1825 (62 5%)
Referred by general practitioner	711 (24%)
Accidents	303 (10%)
Other emergencies	96 (3 5%)
Total	2935 (100%)

Thus nearly two-thirds of the new patients were "casuals", many of whom could have been dealt with by the family doctor Mestitz (1957) in his series found that 80% of the medical patients in the casualty department were casuals

A third (980) of the new patients were X-rayed, and 8% (170) had investigations (other than urine testing) on attending the department The majority of these were culture of pus from septic lesions

The diagnoses are shown in table II

The cases of *trauma* (51%) may be subdivided as follows

Minor trauma	1042 (71%)
Major trauma	22 (1 5%)
Fractures	272 (18%)
Head injuries	94 (6%)
Burns	56 (3 5%)
Total	1486 (100%)

Of the 286 cases of *sepsis* 119 (41%) required surgery

Of the 284 cases classified as *surgical*, 36 (12%) were acute —e g , acute abdomen Of the remaining 248—e g , orthopædic problems, patients with pain in the abdomen, or various swellings, sent to casualty for an opinion—only 57 (23%) required minor surgical procedures in the department

Of the 338 *medical* cases, 78 (23%) were regarded as acute —e g , overdose of barbiturates, coal-gas poisoning, cardiac infarction, hæmatemesis, epilepsy, or cerebrovascular accident Another 50 (15%) had obviously psychiatric illness (not the minor neurosis from which a number of the patients were probably suffering)

The remaining 210 (62%), classified as non-acute, comprised a very wide range of conditions met with in everyday general practice, varying from peptic ulcer and longstanding cardiac failure to constipation, infections of the upper respiratory tract, and the exanthemata

Of the 115 *ophthalmic* cases, 90 (78%) were grouped as minor trauma and foreign bodies, while the other 25 (22%) were not casualty problems but outpatient problems

E N T—Of the 87 *ear, nose, and throat* cases, 68 (78%) were "medical" (the type of case common in general practice) these included tonsillitis, acute otitis media, and acute sinusitis The rest were "surgical"—i e , fishbones in the throat, foreign bodies in the ears or nose, or epistaxis

TABLE II—DIAGNOSTIC CLASSIFICATION

Trauma	Sepsis	Surgical	Medical	Eyes	E N T	Miscellaneous	Total
1486	286	284	338	115	87	339	2935
51%	10%	10%	11%	4%	3%	11%	100%

E.N T =ear, nose, throat

Finally, the *miscellaneous* group of 339 patients included 152 dental cases (5% of the total new attendances), 10 obstetric and gynæcological cases, 48 drunks, 8 cases certified dead on arrival, and 74 in which nothing abnormal could be found This leaves 47 unclassified, such as the woman who wanted her coffee analysed for an aphrodisiac, and a number of overseas visitors who had run out of their tablets, &c , while on holiday in England

Table III relates the main diagnostic groups (table II) to the source of the patient

A comparison of casuals with cases referred by practitioners shows considerable similarity In both groups half the cases were trauma, and about 10% were sepsis In the surgical group, however, there is a higher proportion of cases referred by practitioners Patients were often sent to the casualty officer for a second opinion (in many cases it was a "pre-registration" opinion), for minor surgical procedures, or as a bypass to the outpatient department Under the heading of "medical", the casuals have a much higher proportion of psychiatric cases than the referred patients, but the latter are a selected group in that many were sent to the casualty department as a means of avoiding waiting-lists, or for a second opinion That more of the "miscellaneous" group are casuals is due to the casuals including more dental cases

TABLE III—DIAGNOSTIC GROUPS RELATED TO SOURCE OF PATIENTS (%)

—	Trauma	Sepsis	Surgical	Medical	Eyes	E N T	Miscellaneous	Total
Casuals	50	10	8	10 5	6	3	12 5	100
Referred by general practitioner	48 5	12 5	19	10	1 5	2 5	6	100
Accidents	88		0 5	1	1		9 5	100
Emergencies			4	73			23	100
Total	51	10	10	11	4	3	11	100

TABLE IV—DISPOSAL OF NEW PATIENTS

—	Trauma	Sepsis	Surgical	Medical	Eyes	E N T	Miscellaneous	Total
Reattend	500 (*33%*)	252 (*88%*)	91 (*32%*)	41 (*12%*)	76 (*67%*)	13 (*15%*)	7 (*2%*)	980 (*33%*)
Discharged	490 (*33%*)	10 (*4%*)	33 (*12%*)	95 (*28%*)	25 (*21%*)	28 (*32%*)	203 (*60%*)	884 (*30%*)
Referred to general practitioner	160 (*11%*)	23 (*8%*)	28 (*10%*)	55 (*16%*)	2 (*2%*)	33 (*38%*)	18 (*6%*)	319 (*11%*)
Admitted at once	128 (*9%*)		31 (*11%*)	77 (*23%*)			28 (*8%*)	264 (*9%*)
Referred to another department in the hospital	204 (*14%*)		98 (*34%*)	54 (*15%*)	12 (*10%*)	13 (*15%*)	61 (*18%*)	442 (*15%*)
Miscellaneous*	4	1	3 (*1%*)	16 (*5%*)			22 (*6%*)	46 (*2%*)
Total	1486 (*100%*)	286 (*100%*)	284 (*100%*)	338 (*100%*)	115 (*100%*)	87 (*100%*)	339 (*100%*)	2935 (*100%*)

*e.g , referred to duly authorised officer, self discharges

Of the emergencies—i e , those brought by ambulance —73% were medical, and of these nearly a quarter were classified as psychiatric (This does not include the large proportion of attempted suicides which were classified as acute medical) It is also noteworthy that 4 patients of the accident group were classified as psychiatric They had attempted suicide by physical means but were found to have no physical injuries

Table IV shows the disposal of the patients

Of the casuals, about half were discharged from hospital treatment (table V), 15% were definitely hospital problems, being either admitted or referred to another department, and 35% were retained under the care of the casualty department Of the patients referred by practitioners, 25% were sent back to their doctor, 25% had eventually to be referred to another hospital department, and 9% required admission, although the casualty officer was not responsible for admitting practitioners' patients

TABLE V—DISPOSAL RELATED TO SOURCE OF PATIENTS (%)

—	Re-attend	Dis-charged	Re-ferred to G.P	Re-ferred to other dept.	Ad-mitted	Miscel-laneous	Total
Casual	35	39 5	9	12 5	3	1	100
Referred by general practitioner	27 5	13	25	25	9	0 5	100
Accident	30	18 5	3	9	36·5	3	100
Emergency	1	33	5	7	41	13	100

40% of the accidents and emergencies were admitted On the other hand 17 5% of accidents and 33% of emergencies were discharged on their first visit, although all had arrived in ambulances Mestitz (1957) thought that, of 52 medical patients reaching casualty by ambulance, only 29 needed such transport

Table VI shows the average number of visits (first and subsequent combined) for each diagnostic group, and the number of reattendances for these groups

Taken together, tables IV and VI show that trauma, sepsis, and eye cases accounted for 84 5% of the reattendances, though they formed only 65% of the new cases These groups may be regarded as "specific" casualty problems Patients with "sepsis" paid more visits to the department than any other group The fact that the average number of attendances is 1 8 indicates that most patients are not retained under the department for any length of time.

TABLE VI—NUMBER OF VISITS OF REATTENDERS AND AVERAGE NUMBER OF VISITS FOR A PATIENT ATTENDING THE DEPARTMENT

—	No of visits of reattenders	Average no of visits per patient
Trauma	1015 (*49%*)	1·5
Sepsis	572 (*28%*)	3 7
Surgical	190 (*9%*)	1·6
Medical	110 (*5%*)	1 3
Eyes	151 (*7 5%*)	2 3
Ear, nose, throat	9 (*0 5%*)	1 1
Miscellaneous	18 (*1%*)	1·0
Total	2065 (*100%*)	1 8

There were two reasons for asking patients to come again Firstly, treatment begun in the department and regarded as "casualty treatment" is continued there. The second reason was to check on a case The casualty officer is acutely aware of litigation against his section of the medical profession, and most pre-registration housemen lack the confidence, or clinical judgment, needed to discharge some of the patients who do not require further hospital treatment Reattendances in the department generally fall towards the end of the casualty officer's term of office, when he has acquired more confidence

Discussion

The word "casualty" implies an accident or a serious or fatal event, but present-day casualty work is certainly not confined to accidents Indeed it could literally be called "general practice", for every aspect of medicine is encountered This conforms to the pattern before the National Health Service when patients attended the hospital outpatient or casualty department for all manner of illnesses because they could not afford the doctor's bills With the advent of the N H S , casual attenders might have been expected to disappear from the hospital, but at King's College Hospital the number of new patients has nearly doubled in the past twelve years (see figure)

Present Status of Casualty Department

Agreement has not yet been reached on the part the casualty department should play Should it see all patients who present themselves or should some selection be enforced? In my own series only 60% of cases were "casualty" problems, and of these the majority were minor trauma

Nearly two-thirds of the attendances were by the casual attender Reasons for such visits were

1 Some patients had themselves decided that their problem was one for the hospital—either because they thought it urgent, or because they felt they needed special investigations or treatment.

2 A few patients said that their doctors "would only have sent them to hospital anyway, so they came themselves"

3 Some had tried to contact their doctor, but had failed.

4 The casualty department was always open, and this suited them better than their doctor's surgery hours Also they thought they would have to wait less time in casualty than in their doctor's surgery (In this they were sometimes mistaken.)

5 Some were not on any practitioner's list, or were staying only temporarily in the area and thought they could not call on a doctor

6 A few were dissatisfied with their doctor and wanted a second opinion

7 A proportion were sent from work or school

Are these reasons adequate? I doubt if all of them are In this country everybody is now entitled to a family doctor who should be responsible for his health and welfare If both the hospital and the family doctor are available for the patient to choose between, the result is duplication of services and weakening of the doctor-patient relationship Who should decide whether he goes to the casualty department—the patient himself or his doctor? When he is sure that he will be sent on to the casualty department, the patient naturally wants to avoid an unnecessary visit to his doctor first But, apart from this, some people seem to prefer hospitals to general practitioners

Use of Casualty by Family Doctor

General practitioners referred cases for various reasons

1 Trauma, for an X-ray to exclude bony injury, for suture of lacerations, or for treatment of fractures The X-ray department is not directly accessible to practitioners

2 Septic cases and a proportion of the surgical cases are referred for minor surgery Of the septic conditions referred, two-thirds eventually had surgical treatment

3 Some patients were sent for a second opinion—either directly from the casualty officer or from the outpatient departments to which casualty gives indirect access

4 Some cases were sent for admission without previous inquiry on whether the hospital had a bed for the patient

5 In a small but significant number of cases the patient was sent for social reasons An old lady of 94 arrived with the following note "Will you please admit this patient I can find nothing wrong with her except old age" And some acute "psychiatric" conditions were referred to the department, for "social" reasons

Of these groups the true "casualty" problems were the trauma patients for minor surgery and a small proportion of the cases sent for admission—e g, overdose of drugs These amounted to about 60% of the referred cases The other 40% were a misuse of the casualty department, for they could have been dealt with through other channels

Future of the Casualty Department

Function—To have duplication of medical services is both uneconomical and unnecessary Casualty, like any other service, should have a specific function, and in my view it should deal only with trauma, emergencies (acute medical or surgical cases, 2% in this series), and minor surgery

Design—Dependent upon function, the department should be composed of three units—one for trauma, one for minor surgery, and one for emergencies The trauma unit should have its own beds, and be responsible for inpatient and outpatient care in its specialty

Staffing—The casualty department should be under senior hospital medical staff, who would be responsible for supervising and training the junior casualty officer

Centralisation—Obviously such a casualty department would not be needed in every hospital A given area should have its casualty centre at one particular hospital, where it would be maintained and staffed for its special purpose Centres should be fewer but better at present many of the casualty departments in this country are staffed by the pre-registration house-physician or house-surgeon on duty—people with no casualty experience

The future casualty department should not cater for the casual attender He has his family doctor to consult if he needs medical advice

Summary

This paper analyses 5000 attendances at a south-east London casualty department The patients form a consecutive series seen by one casualty officer

2935 (60%) were new attendances, and nearly two-thirds of these were casual attenders not referred by a doctor Only half the new patients were classified as trauma

In this department the number of new patients has doubled over the past twelve years, though under the National Health Service all patients can go to their family doctor without expense

The present-day casualty department has no specific function and runs as a "general practice" It is misused to a considerable extent both by the public and by their doctors

Future casualty departments should have a specific role Meanwhile more work is necessary both to review existing casualty services and to define their proper function and location

I should like to thank Mr L T Cotton for permission to conduct this survey, and the casualty reception staff for their valuable cooperation My thanks are also due to Dr John Fry for his encouragement and criticism But the views I express are my own

DOCTORS AND NATIONAL SERVICE

THE chairmen of the National Medical Manpower Committee and of the Central Medical Recruitment Committees have issued the following statement

"The announcement made by the Minister of Labour on Dec 14, 1959, that certain persons whose deferment for training or study ends on or after June 1, 1960, will not be called up does not apply to doctors or dentists Doctors liable for National Service have always been dealt with under special and separate arrangements through the three professional committees, which advise on deferments and call-up matters These special arrangements will continue until the end of 1960, when call-up is planned to end

"Under these arrangements deferment granted for completion of studies is continued during the pre-registration year, during which all doctors receive a memorandum setting out the arrangements for call-up and for further deferment

"Doctors who become provisionally registered as medical practitioners on or after Jan 1, 1960, and doctors granted deferment of call-up to a date beyond the end of 1960 need not, subject to fulfilment of their deferment conditions, expect to be called up except in emergency

"All other doctors will, if fit, be considered for call-up in the usual way They will accordingly be nominated for National Service commissions (two years), unless they volunteer to enter the Forces on short service or regular commissions, or unless their call-up is deferred by the Central Medical Recruitment Committees on professional grounds or postponed by the Ministry of Labour on grounds of exceptional hardship

"In 1960 the Forces will still have substantial requirements for medical officers, which will need to be met largely from doctors liable for National Service This means that a considerable number of such doctors must expect to be called up during 1960"

In England Now

A Running Commentary by Peripatetic Correspondents

READERS of the best spy stories have long realised that to qualify for the higher echelons of spying a man must be a polished cracksman, a fluent polyglot, and a perfect shot (knife and gun), he must know the odds and modes of cheating at all games of skill and chance, and (if he is a hero) he must also be an appreciative connoisseur of life, for otherwise the Game would hardly be worth the candle—especially as the candle is usually alight at both ends and will be applied to the soles of his feet sooner or later. Of course, if he is a villain, villainy alone is a sufficient motive.

In view of all this literary conditioning, it is doubtful whether there are many people in England who really believe that spies exist. Ours is a land of charming naïveté where evil is concerned—a land of amateurs. We are not accustomed to consider blackmail, perversion, and revenge as common reasons for adopting a profession so inconvenient as intrigue appears to be. We have built up a melodramatic picture of the spy, and, because in our watercolour country we have come to regard as mildly absurd whatever is vivid, we find the idea of the sinister spy either ridiculous or incredible. Probably we shall never be able to assess the evidence on which the accusation was made that a Communist diplomat set afoot the grotesque plan to poison most of the staff of Radio Free Europe by putting atropine in the saltcellars of the canteen. The idea is too fantastic, the English imagination boggles—and then is tempted into a shamefaced chuckle at the notion of several hundred people simultaneously stuffing themselves with deadly nightshade. As like as not, tasteless jokes about the tastelessness of institutional soup will soon become current in student circles, while dons will quote the *Mithridates* passage from Housman or exchange thin-lipped smiles when the cruet passes between the protagonists of some High Table feud.

With our flippant heritage, how can we fail to look on the Bad Man as an object of pity and of decently moderate derision? Anarchists, nihilists, world-dominators, men who hate women, women who hate men, Nazi fascists, inquisitors, Communist fanatics—we are sorry for them. Why do these people make themselves so wretched, we ask first, and then—why must they also try to make *us* wretched? Can it be that for them happiness is harder work than spying, cheating, lying, destroying, torturing? And if this is true for certain individuals, can it also be true for whole nations? And is extremism always destructive, or is there a cause into which it is right to throw all our energies without reservation? Only one suggests itself: the cause of sanity—in other words, of realism, compassion, humour, and truth. These are virtues which never start wars, although, if necessary, they will *wage* war, invincibly.

* * *

Little attention is usually paid to hospital fauna, but ours at least are interesting.

A pet tortoise survived the whole of the war and on its demise was buried outside the operating block. Its tombstone was inscribed with the touching lines:

" Chloe was a beautiful tortoise,
Even in rigor mortis "

The other day I went into one of the anæsthetic rooms and found a robin perched on a gallipot pecking away at some K-Y jelly which was used to lubricate airways. As I believe that this substance contains glycerin and gelatin, I suppose that he found it sweet and with sound food value.

Last year our neurosurgeon had a surprise. At the end of a craniotomy he asked a nurse to puff his favourite penicillin-sulphanilamide powder into the wound. When she squeezed the bulb, however, a cloud of tiny Egyptian ants emerged. The resulting consternation was mitigated by the bacteriologist, who reported that they were not only sterile but strongly antiseptic. The suggestion that they should in future be sprayed into all wounds has not been followed up.

* * *

My elderly car has just returned to the road after a long illness patiently borne by both of us, and I have been quite touched by people's interest and solicitude.

I used to meet a rubicund man with a large dog every day, and we usually exchanged noncommittal looks, but he waved enthusiastically at my reappearance. A bored-looking woman who is always hanging over her cottage gate, whatever the weather, shouted a greeting. An elderly cyclist, by whose whereabouts on the road I could tell whether I was early or late, made the thumbs-up sign. The butcher in the village grinned and nodded encouragingly as we rattled past his shop. (He once gave me a lift in his van when he saw me panting along towards the hospital at a brisk trot.) And, of course, the porters at the hospital, who had evidently missed my noisy reversings and erratic startings outside their window, came out to admire and congratulate. Even the cows in the fields looked vaguely approving.

The only people who were not sympathetic were the stony-hearted bureaucrats who would not refund the cost of an entirely unused quarterly licence, which ironically enough I had for once renewed in good time.

* * *

She was wearing dark glasses and she said that as she was suffering from nervous debility she thought she would go on the club for a bit. Hoping for a more accurate diagnosis, and to ease my conscience before issuing the inevitable N.I. certificate, I incautiously asked her what she meant by nervous debility. I suppose I deserved her answer: " Well, you're the doctor." I explained that the expression sometimes meant that people were overtired or worried and that it would help me to put things right if she would tell me a little more. " Well, as a matter of fact I've had a blow," she said. " Do you mean the sort of blow you would feel from the loss of a relative, or have you been hit by something? " I inquired. " I've been given a blow by a relative," she replied, and there, as she removed her glasses, was a fine black eye. " You haven't got nervous debility," I said firmly, as I scribbled the Form Med. 1, " you have got a periorbital hæmatoma." I felt better about it that way.

Thoughts on the N.H.S. while reading to my children

" Please pass the buck," the Walrus said
And shed a bitter tear
" You'd think they should have settled this
Instead, they've sent it here
It's travelled round from him to them
And back again to me
From Records to the Ministry
And to the R.H.B.
Initialled *here* by Tweedledum
And *here* by Tweedledee

" Please pass the buck," the Walrus said
" A subcommittee call
And make it large and wide enough
To subcommit us all
In case the matter's surgical
The Carpenter shall speak
And every Hatter madly grin
And every Dormouse squeak.
With any luck the meeting will
Go on for half the week "

" Please pass the buck," the Walrus said
" My conscience must be free
My pidgin isn't medical,
Admin's my cup of tea.
The Service bids us trim our sails
To all the winds that blow
Committees are deliberate—
Who dares to call them slow?
For twenty men will say " perhaps "
When any one says " no "

Letters to the Editor

A CENTRAL LABORATORY FOR OCCASIONAL INVESTIGATIONS

SIR,—Dr Hughes-Davies (Jan 2) raises the question of how the general physician could gain access to specialised laboratory services, and suggests a national biochemical reference laboratory, on the lines of the bacteriological reference laboratories

The problem, however, is not quite the same as in bacteriology, either in the pattern of work of such a central laboratory or in the numbers of specimens likely to be submitted, and to establish a worthwhile central laboratory for clinical biochemistry presents formidable problems Few physicians have any idea of the amount of work which can result from a request which may take only a few seconds to write, and not all physicians would restrict their calls on such a laboratory to the occasions where its help is really necessary If, for example, the laboratory were to offer to measure urinary catechol-amine excretion, many physicians might come to regard this analysis as part of the routine investigation of hypertension From the patient's point of view this may be justified, however long the odds may be against finding a significantly increased excretion, but the effect of such requests, on a national scale, would be to make the central laboratory quite unworkable It is also possible to visualise, in advance, the flood of M D theses, both good and bad, which could arise from the work of such a laboratory if it attempted to meet all calls made on it

A more practicable arrangement might be for each of the larger laboratories in a region to make itself responsible for two or three of the more technically exacting analyses, and for requests to be passed on to these laboratories through local biochemists or clinical pathologists Unofficial arrangements of this sort already exist in many areas, but to put such arrangements on a more general footing should not be unduly difficult It is, I think, very desirable that such arrangements should be of a strictly regional character, since otherwise it is hardly practicable for the request to be discussed between the biochemist and the physician concerned, and it is also desirable that physicians should understand the right of the senior laboratory worker to query, and on occasions defer or reject, a request which may take him many hours of work to meet and of whose necessity he is not convinced Work of this character is not performed by junior technicians, and it is necessary for the man at the bench to be reasonably satisfied that his efforts are not being wasted

Royal Infirmary, Edinburgh

S C FRAZER

SIR,—On the face of it, Dr Hughes-Davies' suggestion that the National Health Service should establish a central laboratory able to make certain tests on a routine basis appears to be quite good It does, however, overlook the fact that there are now a large number of group or area laboratories in the National Health Service which are already undertaking most of the tests he has mentioned There may be some difficulty about hormone investigations requiring maintenance of large stocks of animals, but many biochemical estimations, sometimes regarded as infrequently required, are now routine tests in the larger laboratories Moreover, many group laboratories have an interchange system whereby a laboratory can supplement its own battery of tests by referring special work not usually done by it to another group laboratory

The suggestion made by Dr Hughes-Davies also does not take account of the fact that the most important part of a test is interpretation of the result in relation to the patient, expert guidance of this kind is not always easy to obtain from a central laboratory which gives only a postal service

CHROMOSOME STUDIES IN LEUKÆMIA

SIR,—In their letter of Oct 31, Dr Ford and Dr Mole make one interesting and justifiable comment on the interpretation of our observations in relation to the occurrence of chromosomal abnormalities in human leukæmia We would agree that it is possible that the absence of chromosome abnormalities in our cultures of marrow from patients with one or other type of chronic leukæmia is due to the leukæmic cells not having divided in culture This being so, the cells of an apparently normal chromosome constitution which we observed would be derived from normal marrow elements It is now possible, however, to test if any unusual numbers of cells were present in these cultures with chromosome counts differing from the modal number by calculating the expected numbers of cells with typical and atypical (non-modal) counts and comparing these numbers with the observed numbers[1] If a small but significant excess of atypical cells were present there would be some justification for believing that we were observing some abnormal leukæmic cells but, because of their small number, classifying them as artefacts We have now made such calculations for 8 cases of chronic leukæmia (5 of chronic myeloid and 3 of chronic lymphatic) inclusive of the cases reported in our paper (table I) From these calculations it can be seen that there is no difference between the expected and observed numbers of non-modal cells in the marrows from patients with chronic lymphatic leukæmia In those from patients with chronic myeloid leukæmia there is a small excess of atypical cells but this may well be due to the play of chance ($\chi^2 = 2\ 40$, P > 0 1)

We feel, therefore, that, if the cells of chronic leukæmia carry a chromosomal abnormality, the abnormality may be of such fineness as to be below the visual threshold of our technique We cannot exclude, however, the possibility that visible abnormalities may occur but remain hidden from us because either the culture times are too short or the conditions of culture are harmful to these types of cell

WHAT TO EXPECT FROM OUR BABIES

SIR,—The reader of your annotation of Jan 2, dealing with a recent special report of the Medical Research Council, might legitimately conclude, if he had not had the opportunity of studying this interesting report, that the author's claim to have established weight standards for the first year of life, according to birthweight, based on examinations of over 700 infants

Although reasons are given in the report for assuming that the 15% of cases remaining in the sample at the age of 8–12 months is representative of the sample as a whole, it would not seem reasonable to accept as standards mean weights based, for example, at 5–6 months on 5 cases in the 2–3 lb birthweight group, 8 in the 3–4 lb, and 23 in the 4–5 lb groups Nor can it be said that the findings in this report disprove the supposition that many infants smaller at birth remain at the lower end of the normal weight scale

---

[1] Court Brown, W M , Jacobs, P A , Doll, R *Lancet*, Jan 16, 1960, p 160

Current studies in Edinburgh indicate that the prematurely born tend to remain smaller than average in the preschool period, and though this can be attributed in part to less favourable environment and small parental stature, many of those in the 2–3 lb birthweight group remain markedly undersized well into the school-age period, even when there is no obvious effect of environmental or genetic factors In these cases at least " the accident of gestational age " appears to have a marked effect on the " inborn pattern of body size "

MEDICAL JOURNALS FOR DOCTORS IN DEVELOPING COUNTRIES

Sir,—Your account (Jan 2) of the scheme which is being started to enable British doctors to send their medical journals on to colleagues oversea is doubly gratifying, first, because of the excellent project that you describe, secondly, because you refer to *developing* countries and only permit " underdeveloped " to appear between quotation marks It has become customary to refer to " underdeveloped countries ", but this is scarcely a satisfactory designation There are many underdeveloped countries, such as Australia, which are not being referred to, and the phrase has a rather unpleasantly patronising flavour I therefore hope that others will follow your example, and that " underdeveloped " will no longer be used to designate newly developing countries

Orpington,
Kent

L M Franklin

THE COST OF DRUG TREATMENT

Sir,—The article in your issue of Jan 2 by Dr Miller and Dr Smith is full of most useful information and, in general, appears to be an objective report on a problem which has, in many other quarters and on many occasions, been treated in anything but an objective manner There are, however, features of the article to which I feel that further attention should be drawn, particularly as those features have led to quotation (or misquotation) in the *Daily Express*

The feature to which, from the pharmaceutical standpoint, the greatest exception is taken is the quoting of the " basic cost " per week of phenobarbitone therapy and the development from it of the contention that the chemist-contractors' remuneration increases the cost by more than 1600% If I were to contend that on each patient whom a medical practitioner has on his list and who requires no attendance or other service during the year, the medical practitioner makes an astronomical *percentage* profit I would be just as accurate but just as unfair as Dr Miller and Dr Smith

They also draw attention to the fact that in their calculations a flat-rate dispensing fee of 1*s* 2*d* has been added to the basic cost " but that in fact this is the minimum " By quoting one higher fee of 4*s* 0*d* they imply that the minimum fee is not the fee usually met with In fact, the national average dispensing fee, assessed over 200,000,000 prescriptions, is 1*s* 2 8*d* , and it should be noted that that level of remuneration was only conceded by the Ministry of Health after the most exhaustive costing investigations and subsequent " negotiations " in which figures to the fourth place of decimals featured prominently and in which all increases in salaries and overhead costs which have occurred since 1956 were completely disregarded.

As to the contention of Dr Miller and Dr Smith that because " rather more than three-quarters of all National Health Service prescriptions are for tablets " their " dispensing does not call for any high degree of professional skill ", they are, in my view, adequately and best answered by the fact that (as the Minister of Health has, himself, said) " the role of the pharmacist is vital in the handling of these products " and has led to an increase in the severity of the educational standards required for entry into and subsequent qualification in the pharmaceutical profession

THROMBOTIC THROMBOCYTOPENIC PURPURA

Sir,—Dr Bernstock and Dr Hirson's paper of Jan 2 quotes several examples from the literature. Presumably because the paper was written before our case was published[1] they have not had an opportunity to comment on that This might be an opportunity to point out that our child, who was $2^1/_2$ years of age at the onset of the disease, completely recovered, following a five-week course of cortisone There was no clinical or hæmatological relapse subsequently, and to date, two years after his admission, he is a perfectly normal little boy

PROPHYLAXIS IN THROMBOEMBOLISM

Sir,—In a leading article on Dec 5 you stated " What little theoretical understanding we do have is still based on the triad of causes enunciated with extraordinary vigour and lucidity by Virchow " It is probably that because it was said with vigour by a master we cling to this concept and give little attention to other probable explanations

It can be stated with considerable assurance that two of the factors of the triad—namely, altered coagulability of the blood and impaired circulation—are rarely, if ever, primary in the causation of intravascular clotting In fact, it is still a moot question whether hypercoagulability has ever been unequivocally demonstrated Progress in understanding thrombosis and abnormal bleeding has been hampered perhaps more by the myth that the clotting-time is a measure of physiological coagulability than by any other theory of coagulation

Coagulability implies formation of thrombin, and the defence against massive intravascular clotting is the prompt removal of this clotting factor from the circulating blood. In a recent study, my associates and I[2] have reconfirmed the observation that when thrombin is injected intravenously at a slow steady rate, it does not cause thrombosis We offer the explanation that thrombin is promptly removed by adsorption to the surface of fibrin fibrils which are rapidly removed from the circulating blood.

The thrombin that gives rise to a pulmonary embolus is generally regarded as having its origin in the peripheral venous system It has been postulated[3] that it may be initiated by a localised injury of a vessel wall Such an injury liberates enough tissue thromboplastin to cause the formation of the primary clot attached to a vessel wall When this clot retracts, it expresses a serum rich in nascent thrombin If this serum is not promptly swept into the circulation, a secondary clot attached to the primary thrombus is produced By a multiple repetition of this process, the thrombus grows in the direction of the blood-stream and when dislodged from its mooring becomes a pulmonary embolus

The success of anticoagulant therapy, as again convincingly demonstrated by the excellent paper of Sevitt and Gallagher,[4]

---

1 Lorber, J , Emery J L *Proc roy Soc Med* 1959, 52, 301
2 Quick, A J Hussey, C V , Harris J , Peters, K *Amer J Physiol* 1959, 197 791
3 Quick, A J *Practitioner*, 1951, 166, 213
4 Sevitt, S , Gallagher, N G *Lancet*, 1959 ii, 981

can be explained satisfactorily by the above theory The prompt neutralisation of thrombin by heparin or the depression of the thrombinogenic activity of the blood by a drug decreasing prothrombin activity effectively prevents the growth of the thrombus because the clotting activity of the expressed serum is greatly reduced by either agent

Milwaukee, Wisconsin
ARMAND J QUICK

THE NATURE OF ESSENTIAL HYPERTENSION

SIR,—In your review (Jan 2) of *Medical Surveys and Clinical Trials*, edited by L J Witts, you say "Once again the professional habit of dividing normal from abnormal systolic blood-pressure at about 160 mm Hg appears to be reasonable" I would be greatly obliged if you or any of your readers would furnish me with the evidence on which this statement is based

Oxford
G W PICKERING

*** The evidence was discussed in our leading article of Nov 21 and the letters we have since printed Sir George interprets our review as suggesting that the issue is settled —which would certainly be going too far The customary division between normal and abnormal pressures was described only as "reasonable"—ED L

CASE-FATALITY IN TEACHING AND NON-TEACHING HOSPITALS

SIR,—In 1957 we showed[1] that there was a higher case-fatality for certain conditions in non-teaching hospitals than in teaching hospitals This study was based on the data collected by the General Register Office in the national Hospital Inpatient Morbidity Enquiry for England and Wales in 1951 and in 1953–54 The collection of data has continued, and that for 1955 has recently been published.[2,3] We have tried to analyse this new material, together with some additional unpublished data supplied by the General Register Office and the Ministry of Health, in the same way as the earlier

TABLE I—NUMBER OF CASES OF HYPERPLASIA OF PROSTATE, NUMBER OF DEATHS AND CASE-FATALITIES IN TEACHING AND NON-TEACHING HOSPITALS, 1953–54 AND 1955 (MEN AGED 45 YEARS AND OVER)

—	1953–4		1955	
	Teaching hospitals	Non-teaching hospitals	Teaching hospitals	Non-teaching hospitals
Cases	290	729	112	671
Deaths	12	70	4	101
Case-fatality	4 1%	9 6%	3 6%	15 1%
Case-fatality standardised for age and mode of admission*	4 1%	7 8%	3 6%	11 3%
	(P<0 05)		(P<0 05)	

* Using the age structure, and the proportion of "immediate' admissions, of the teaching hospital cases in each period as the "standard" population

As time passes, the General Register Office and the Ministry of Health are able to make the Hospital Inpatient Morbidity Enquiry more representative The 1955 material includes effectively random samples of the patients discharged from very large numbers of non-teaching hospitals, including those of two complete regions, and from nearly half the teaching hospitals in England and Wales However, the use of the same sampling fraction (10%) for both teaching and non-teaching hospitals means that in many conditions the number of cases and deaths reported by the teaching hospitals is very small Because of this the data for appendicitis and for diabetic coma, for both of which there was a marked difference in the experience of teaching and non-teaching hospitals in the earlier study, cannot usefully be analysed for 1955 But there were enough cases and deaths from hyperplasia of the prostate and from perforated peptic ulcer in the 1955 material for analysis in some detail

TABLE II—NUMBER OF CASES OF PERFORATED PEPTIC ULCER, NUMBER OF DEATHS AND CASE-FATALITIES IN TEACHING AND NON-TEACHING HOSPITALS, 1953–54 AND 1955 (MEN OF ALL AGES)

—	1953–4		1955	
	Teaching hospitals	Non-teaching hospitals	Teaching hospitals	Non-teaching hospitals
Cases	144	280	52	240
Deaths	12	33	9	31
Case-fatality	8 3%	11 8%	17 3%	12 9%
Case-fatality standardised for age*	8 3%	9 8%	17 3%	10·6%
	(P>0·05)		(P>0 05)	

* Using the age structure of the teaching hospital cases in each period as the "standard" population

Hyperplasia of the Prostate

Case-fatalities in the two types of hospital in 1955 are shown with those of 1953–54 for comparison, in table I There is a significantly lower case-fatality among the teaching-hospital patients (3 6% compared to 15 1%) The different age-distribution of patients in the two types of hospital, and the different proportions of "immediate" or emergency admissions to them have made little contribution to this difference in case-fatality as is shown by its persistence (3 6% and 11 3%) when these factors are allowed for by simple standardisation

Some cases admitted to hospital with *retention of urine* were given no more specific diagnosis, they will certainly have included men with hyperplasia of the prostate For the period 1953–55, there were 49 such male cases aged over 45 reported by teaching hospitals, and 304 by non-teaching hospitals The case-fatality among these patients, when standardised for age and mode of admission in the same way as the cases definitely described as suffering from hyperplasia of the prostate, was 4 1% in the teaching hospitals and 15 0% in the non-teaching hospitals The relatively greater use of this less precise diagnosis by non-teaching hospitals cannot therefore have produced the observed difference in case-fatality in hyperplasia of the prostate

The death rate from hyperplasia of the prostate in England and Wales as a whole fell by 27% between 1951 and 1957[4] There are no data on case-fatality later than 1955, but clearly the analysis of the 1956 and 1957 results of the Inpatient Morbidity Enquiry will be very interesting

Perforated Peptic Ulcer

In 1951–54 case-fatality from perforated peptic ulcer was somewhat higher in the non-teaching hospitals This difference was small and it was less regular than for hyerplasia of the prostate

There were just sufficient numbers of cases and deaths from this condition reported in 1955 for separate analysis The

TABLE III—NUMBER OF SURGEONS PER 1000 SURGICAL BEDS, IN TEACHING AND NON-TEACHING HOSPITALS, NATIONAL HEALTH SERVICE, ENGLAND AND WALES, 1958

Staff	Teaching hospitals	Non-teaching hospitals
Consultants	26	17
Senior hospital medical officers	0 3	1 8
Senior registrars	18	2 2
Registrars, junior hospital medical officers	29	22

This table includes all surgeons appointed in general surgery, traumatic and orthopædic surgery, urology, plastic surgery, thoracic surgery, and neurosurgery, and all staffed beds in these specialities

[3] *Lancet*, 1959, ii, 416

[4] General Register Office Unpublished

TABLE IV—NUMBER OF ANÆSTHETISTS PER 1000 SURGICAL BEDS IN TEACHING AND NON-TEACHING HOSPITALS, NATIONAL HEALTH SERVICE, ENGLAND AND WALES, 1958

Staff	Teaching hospitals	Non-teaching hospitals
Consultants	18	10
Senior hospital medical officers	0·7	2·7
Senior registrars	5·8	0·6
Registrars, junior hospital medical officers	20	8·9

Surgeons and anæsthetists employed part-time in any of the above grades have been converted to a whole-time equivalent on the basis of 38½ hours per week.

result of this is given in table II The advantage in 1955 lay with the *non-teaching* hospitals Such a reversal suggests that there is no real difference between the case-fatalities from perforated peptic ulcer in the two types of hospital

Staffs of the Two Types of Hospital

In our earlier paper we commented on the substantial differences in the staffing ratios of teaching and non-teaching hospitals Figures for 1958–59 have kindly been made available to us by the Statistical Division of the Ministry of Health (tables III, IV, and V) There has been little change since 1953 Data on numbers of house-officers in the two kinds of hospital are not available for 1958 No regional analysis has yet been attempted

Characteristics of Patients

The point was made in correspondence[5] on our original paper that the social class of patients may affect their prognosis to an important extent, and that the distribution of patients by social class was likely to be different in the two types of hospital Unfortunately, the General Register Office were unable to obtain the current, or most recent, occupation (whence "social class" is derived) from hospitals in 1951–55 for more than a small proportion of the patients We hope to be able to study this question later as a renewed attempt is being made to collect data on occupations

TABLE V—NUMBER OF NURSES PER 100 BEDS IN TEACHING AND NON-TEACHING "ACUTE" AND "MAINLY ACUTE" GENERAL HOSPITALS, NATIONAL HEALTH SERVICE, ENGLAND AND WALES, 1959

Full-time		Part-time	
Teaching hospitals	Non-teaching hospitals	Teaching hospitals	Non-teaching hospitals
84	49	3	12

No data are available on the distribution by surgical or medical beds, or on the whole-time equivalent of part-time nursing staff.

We are also making a more detailed study, in collaboration with one regional hospital board and board of governors, of their patients with hyperplasia of the prostate Information about the occupations will be available An attempt is also being made to classify patients by their clinical condition before operation, and to analyse postoperative morbidity as well as mortality in the two types of hospital

Beds for the Chronically Ill

The possibility is sometimes raised that the presence of beds for the chronically ill in the non-teaching hospitals may increase their case-fatalities for such conditions as hyperplasia of the prostate,[6] and that these may also influence the staffing ratios and make their interpretation difficult. The data in the Hospital Inpatient Enquiry are based on the patient's total duration of stay, without regard to transfers *within* the hospital The number of long-stay patients in the non-teaching hospitals discharged or dying with a diagnosis of hyperplasia of the prostate cannot be large, for the durations of stay with this diagnosis are similar in the two types of hospital Moreover, it has already been shown that the extra mortality in the non-teaching hospitals could not be accounted for by such long-stay patients as they did have[1] The ratios of surgeons and anæsthetists are of course calculated per 1000 *surgical* beds, and are unaffected by the presence or absence of other types of accommodation, such as beds for the chronically ill, in the hospital The ratio of nurses to beds (table V) is in fact closely similar in non-teaching hospitals whether they are altogether "acute" or "mainly acute"

We are grateful to the General Register Office and the Statistical Division of the Ministry of Health for their help

THE CONVALESCENT EXCRETER OF SALMONELLÆ

SIR,—Dr Schrire (Jan 2) is unduly optimistic when he reports that few patients continue to carry *Salmonella typhimurium* or other intestinal pathogens after treatment In my experience the antibiotics so far available seem to have little effect on the salmonella carrier, nor does furazolidone fare better At Coppetts Wood Hospital 11 patients suffering from salmonella food-poisoning were treated with antibiotics (tetracycline, chloramphenicol, or streptomycin) and at the end of the course 9 continued to excrete the organism A further 7 patients were treated with furazolidone but with no greater success, for all became convalescent carriers The results of treating 8 cases of Sonne dysentery with furazolidone were equally disappointing, for in each case we obtained positive stool-cultures on completing treatment With such uniformly poor results furazolidone would appear to be of little value in treating the human salmonella carrier or the carrier of *Shigella sonnei*

Coppetts Wood Hospital,
Muswell Hill, London, N 10

RONALD T D EMOND

THE ABNORMAL APPENDIX

SIR,—In his helpful and readable article of Dec 26, Mr Jewers reiterates the feasibility and importance of early diagnosis and removal of the acutely inflamed appendix This general diagnosis covers a variety of clinical pictures, each dependent on the position of the inflamed organ and with its own particular differential diagnosis

While one cannot quarrel with Mr Jewers' paramedian incision, I suggest that easy and adequate approach can equally be by appropriate incision over the inflamed organ high muscle split in the flank for retro- or para-cæcal, transverse pararectal with lateral muscle-split extension and preservation of intercostal nerve and inferior epigastric blood-vessels for tethered retromesenteric and iliac, and lower midline for pelvic, or where peritonitis has developed Diffuse peritonitis is treated by early placement of damp mops, changed at intervals during the operation until they come out apparently clean, and the abdomen is closed without drainage

Transperitoneal drainage with a red-rubber tube of a localised inflammatory mass may be likened to the gastroscopic investigation of a wasps' nest on a drowsy summer afternoon, and may be the cause of fæcal fistula and adhesions

Acute intestinal obstruction, either of the small gut or of the appendix by a stercolith, is not amenable to conservative treatment The tethered retromesenteric inflamed appendix in particular must be removed early in order to forestall retromesenteric peritonitis, lower small-gut obstruction, and portal pyæmia

Mr Jewers' paper and his references are worthy of study

Royal East Sussex Hospital,
Hastings, Sussex

EARLY DIAGNOSIS OF PREGNANCY

SIR,—I was very interested to read Dr Foster's letter[1] on the early diagnosis of pregnancy using 'Disecron' and in Dr Hobson's doubts.[2]

I should like to mention a test for the early diagnosis of pregnancy which I described in 1954. At that time, we first examined the cervical mucus to find out whether crystallisation "like fern leaves" took place, but we have now modified the method and give straight away 2 mg. of œstradiol benzoate and 50 mg. of progesterone together intramuscularly.

We have used the method in more than 350 cases of delayed menstruation, and results have been excellent. Two to eight days after the injection in all cases of non-pregnancy menstruation appears, and in all pregnancies no menstruation follows.

Dr Hobson objects to the injection of steroid material because "we cannot be certain that the resulting hormonal imbalance, however small, may not itself cause an abortion in susceptible women." But, in my experience, exactly the opposite happens. The steroids seem to have a beneficial effect on the fertilised ovum in women of low fertility by modifying the endometrium favourably.

After more than 350 tests, the accuracy of the method using 2 mg. of œstradiol benzoate and 50 mg. of progesterone is better than the Aschheim-Zondek test (especially when frogs are used). The test is reliable, economical, and practical.

Toronto. L. G. POLYMENAKOS.

AN ILLNESS OF INFECTION IN CHICKENPOX

SIR,—An "illness of infection" was first recognised in measles by Goodall[3] in 1925. He described 4 patients who had a transient febrile illness within a day or two of exposure to measles. This was followed by a period of apparently normal health before the usual prodromal symptoms and measles rash appeared. Since that time over 30 cases have been reported in the literature. It is estimated that about 10% of patients with measles have an illness of infection. It has also been recognised that a small proportion of patients have symptoms throughout the incubation period.[4]

It is quite possible that similar phenomena occur in other infectious diseases but the symptoms or clinical features are so mild that they escape notice. Recently an opportunity arose to test this in chickenpox.

One day the eldest boy (aged 11) of a family developed malaise, generalised aches and pains, and fever. Next day he had a characteristic chickenpox rash. Twice-daily oral temperatures were taken from all members of the family for the next 15 days. No attempt was made to isolate the child.

The temperature records are shown in the accompanying figure. The first record is that of case 1, the boy already described. Case 6, the father, had previously had chickenpox, and his temperature stayed below 98·6°F for the whole of the observation period. All the rest of the family had typical chickenpox in due course. Case 5, the mother, had a temperature of 99·6°F in the evenings of the third and fourth days of case 1's illness. During the same period the other 3 children had at least one temperature recording of 99°F, and case 4 had a reading of 99·6°F. None of them complained of symptoms. Thereafter the temperatures of cases 3, 4, and 5 remained below 99°F until the fever began before the rash appeared.

Case 2, a girl of 7 years, showed a slightly different pattern. She had a temperature of 99°F or over on the third, fourth, seventh, and tenth days of the incubation period before prodromal fever developed.

These observations are clearly no more than preliminary and suggestive. Their interest, if confirmed, is at least threefold. First, it may be possible to identify a few more of the many unexplained fevers. Second, when known exposure has occurred, it may be possible to predict that a particular person will develop the disease (the converse is not true). Lastly, these small rises of temperature provide some clinical support for the pathogenesis of the acute specific fevers outlined by Fenner.[5]

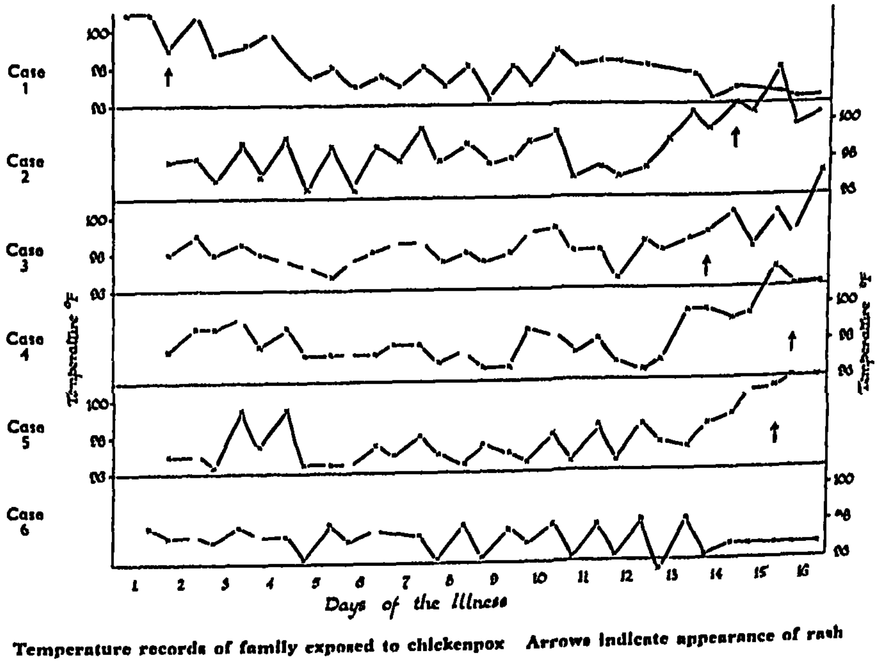
Fenner suggested that first there is a local invasion of the body by the virus. This is followed by a viræmia. The virus then settles in the viscera, probably in the reticuloendothelial system. It multiplies here during the incubation period and then issues forth in a further viræmia or series of viræmias. These, together with peripheral invasion of the skin, respiratory tract, &c. are responsible for the customary clinical features of the disease. In this view the illness of infection represents the first viræmia or systemic spread of the organism.

Fenner's theory was based on laboratory work with mousepox. Clinically, the onset of measles is consistent with his hypothesis. The present findings suggest that a similar train of events could well occur in chickenpox.

It should be possible to confirm or refute these observations by taking the temperatures of all exposed persons during an outbreak of chickenpox in other families, hospitals, nurseries, or schools.

I wish to thank Mr I. Foster of the Royal Infirmary, Sheffield, for the figure, and my family for being such patient guineapigs.

Toronto. M. W. PARTINGTON.



Temperature records of family exposed to chickenpox. Arrows indicate appearance of rash.

EMERGENCY RESUSCITATION IN RUPTURED ECTOPIC GESTATION

SIR,—Mr Azie (Dec 12) is to be congratulated on his successful treatment of a formidable case of ruptured ectopic pregnancy in difficult circumstances, and for advocating the method of autotransfusion which is so much neglected in this country nowadays

It is surely the ideal method of transfusion—the blood is perfectly compatible, it has been kept at body-temperature, it is to some extent defibrinated, it needs little or no anticoagulant, and, as Dr Burrowes (Dec. 26) has told us, it is acceptable to a Jehovah Witness The modern generation in this country has lost sight of the method, or more probably has never known it one recalls the story of the evacuee child at the beginning of the late war who said after seeing a cow milked that at home they didn't get milk like that but out of a nice clean bottle The increasing use of suction in theatres also perhaps tends to discourage it

I have found that the easiest way to collect the blood is to have a borrowed soup ladle sterilised with the instruments, but the main difficulty nowadays is to find a suitable container to put the blood in. While perhaps the method is indicated only in the fulminating sort of case described by Mr Azie and Professor Chassar Moir (Jan 2) with a massive hæmorrhage, it would be unfortunate if the method were to fall into disuse in this country, and it is time we realised that we cannot always expect to live in a perpetual lotus-land, with, among other things, endless supplies of preserved blood easily available

Middlesbrough BRYAN WILLIAMS

SIR,—Mr Azie's letter reminded me of the early post-war years when blood-transfusion facilities were very poor even in large surgical centres in Greece At that time it was the rule to try to retransfuse as much of the intra-abdominal blood as possible, and this procedure has been used at the Athens State General Hospital not only in cases of ruptured ectopic gestation but in every case of intraperitoneal hæmorrhage

I remember a patient with a stab wound who immediately after the opening of his abdomen under local anæsthesia received more than 200 ml of his own blood before it became evident that his stomach had a perforating wound from which gastric juice was leaking out. The patient developed no reaction whatsoever after this erroneous autotransfusion, and under penicillin cover only he made the smoothest post-operative recovery

During the same period we also used autotransfusion successfully during aseptic major operations involving accidental or inevitable profuse intraperitoneal bleeding

As Mr Azie states, "this simple method could be applied by any doctor with little or no assistance in a remote hospital" I would add that although this method should be in the mind of every surgeon it should not be used when blood-transfusion facilities are available or when the aseptic condition of the intraperitoneal blood is suspect because of an intestinal injury or otherwise

Laikon Hospital,
Athens N J GEORGIADIS

SIR,—It was very pleasing to read the letter from Sir Claude Frankau in your last issue, for at that time I was in Bethune and was shifted as surgical specialist to the 7th Div clearing station at Aire close by

At the battle of Neuve Chapelle in March, 1915, and later in that of September 25, we who drained the front line opposite us, regularly used peritoneal blood for resuscitation and thought little of it, for the simple reason that for long prior to the war in my own hospital, the Eden, Calcutta, it was a hospital standing order that in every case where blood from whatever cause was extravastated into the abdomen, it should, after filtering, be reintroduced into the blood-stream The only obligation being in those days that the vessel to contain the blood should contain not less than 1 oz of 1% sodium citrate solution, and that the actual blood that was "cupped" from the belly should be filtered through not less than 12 layers of plain white gauze

I can recall hearing of Captain Fraser's success at Bethune but in the flurry of war it raised no eyebrows in the Meerut C C S of Major Goodwin, for very shortly after, we were all waiting on the very original work of Kenneth Walker who had initiated direct blood-transfusion

Looking back over the years and recalling the tragedy of the Battle of Loos, I have no doubt whatever that we saved many lives by what in those days were dubbed by Lilliputians, "Oriental ways"

London, W 1 V B GREEN-ARMYTAGE

EVENING COLIC IN INFANTS

SIR,—Dr Tuckman's criticism (Jan 2) of the figures for the dicyclomine study are legitimate, but they omit certain other relevant data

To reiterate, of 16 babies receiving the inert substance, 8 were unaffected, and the remaining 8 were given a total score of 19, the mean score being +1 18 Of 20 receiving the active drug, only 1 was unaffected, the remaining 19 being given a total of +47, the mean score being −2 35

Three mothers found the inert substance more effective than the active drug, the total difference being −5 Nine mothers found the active substance better than the inert one, the total difference being −20

Five mothers stated that one bottle was useless, and the other very effective, and in each case the one considered useless contained the inert substance.

I think that my conclusion that the drug is of value is justified

INTESTINAL ABSORPTION OF VITAMIN B_{12}

SIR,—The paper [1] by Reizenstein and Nyberg on the intestinal absorption of liver-bound radiovitamin B_{12} was of especial interest to us in relation to current studies in our laboratory with 5, 6-dimethylbenzimidazolyl cobamide coenzyme ("coenzyme B_{12}") *

Barker's group, which isolated this material from liver, presented evidence suggesting that this coenzyme B_{12} may be the metabolically active form of vitamin B_{12} as well as the main storage form in the liver [2] The possibility was raised that this material might be absorbed from the intestine more readily than vitamin B_{12} in the absence of intrinsic factor

Our preliminary studies with "coenzyme B_{12}" suggest that

(1) In vitro, coenzyme B_{12} appears to compete with vitamin B_{12} in a 1 1 ratio for attachment to intrinsic factor on liver homogenate receptors

(2) Patients with pernicious anæmia in relapse show optimum hæmatological and clinical responses to the daily intramuscular injection of 1 μg of either coenzyme B_{12} or vitamin B_{12} At this intramuscular dosage level, coenzyme B_{12} and vitamin B_{12} appear equal in their effects

(3) The absorption of small (2 μg) oral doses of radioactive coenzyme B_{12} † appears to be less dependent on intrinsic factor than the absorption of similar doses of vitamin B_{12} itself as suggested by our preliminary studies with Schilling-type testing [3] using ^{57}Co coenzyme B_{12}

---

* Supplied to us by Dr H A Barker Department of Biochemistry, University of California Berkeley 4, California and Dr David Perlman, Squibb Institute for Medical Research New Brunswick, N J

† The radioactive ^{57}Co coenzyme B_{12} was obtained through the courtesy of Dr David Perlman, Squibb Institute for Medical Research, New Brunswick, N J

1 Reizenstein, P G Nyberg, W *Lancet* 1959, ii, 248
2 Weissbach, H , Toohey, L , Barker, H A *Proc Nat Acad Sci* 1959, 45 521
3 Ellenbogen, L , Williams, W L *Blood*, 1958, 13, 582

We would speculate that the liver-bound B_{12} of Reizenstein and Nyberg and coenzyme B_{12} of Barker may be the same substance. Further studies are indicated to test both this possibility and the possibility that coenzyme B_{12} may be less intrinsic-factor-dependent for intestinal absorption than vitamin B_{12} itself.

RADIOLOGY IN PERNICIOUS ANÆMIA

SIR,—We should like to correct two points in your annotation "Gastric Outline and Motility" (Jan 2) concerning our radiological findings in the stomach in pernicious anæmia. On examining 69 patients with pernicious anæmia in remission we found, in 53, a combination of features which we believed indicated gastric atrophy (*not gastritis*). These were, as stated, a smooth tubular longitudinal gastric segment, a smooth fundus devoid of normal folding, fine "crushed tissue-paper" rugæ *in the* empty *longitudinal* part of the stomach with normal rugal pattern in the transverse part. The stomachs were of small volume and emptied rapidly so that they could *not be distended. This was partly due to the* peristalsis which was quite active and not poor, as stated in your annotation. We think this point is important because in the only case *in the series where peristalsis* was absent in the body of the stomach a "leather bottle" type of carcinoma of the stomach was present. Details of the findings in these patients with pernicious anæmia and in the control group are awaiting publication.[1]

R G PITMAN.

OBESITY

SIR,—Dr *McMullan in his letter* of Jan 2 writes "There is nothing inherently improbable in the idea that certain people—even most people—are able to respond to excessive food intake by increased metabolism." This thesis was set out nearly 50 years ago by Grafe,[2] who postulated such a *luxus Konsumption* mechanism since then, it has been widely discussed but has received no satisfactory experimental support. I used to think that it was probably correct and five years ago with some colleagues tried to get good evidence to confirm the thesis.

We[3] gave three constitutionally thin young men diets containing 1300–1600 calories in excess of their requirements for periods of 10–14 days. During this time they followed a standard regime in a metabolic ward. Metabolic-rates were determined by indirect calorimetry at 4-hourly intervals throughout 24-hour periods. There was no evidence that any of the excess food was oxidised, apart from a small amount due to the rise in metabolism attributable to the specific dynamic action of the extra protein eaten. There can be no doubt that these three young men possessed no *luxus Konsumption* mechanism.

In the continued absence of any positive experimental support for this thesis, it seems unlikely that normal people possess an ability to metabolise directly any dietary excess.

University of Edinburgh

R PASSMORE

POSTOPERATIVE DIARRHŒA

SIR,—Mr Shipman (Dec 12) points out that, once diarrhœa has commenced, the transit time of methylene-blue through the bowel is shortened.

The transit time should be accepted with caution, owing to the rapidity with which methylene-blue diffuses through a liquid *medium. The only explanation of the* continuing dilatation of the bowel in these patients is the presence of some degree of "hold-up" or stasis of the intestinal contents.

But it is the state of the bowel before the onset of the diarrhœa which is important from the ætiological point of view. In my cases, there was a *highly significant association* between intestinal stasis and the subsequent development of diarrhœa. During the period of stasis, constipation was almost invariable, so it was not possible to estimate the transit time through the bowel.

Victoria Infirmary,
Glasgow

GRAHAM SCHOFIELD

FLOW-METER FOR EXTRACORPOREAL CIRCULATION

SIR,—We were interested to read of the extracorporeal-circulation blood flow-meter described by Dr Nixon (*Nov 14*). *Several of our associates have made similar* suggestions, but we do not agree that such a device gives a reliable guide to the blood flow-rate under clinical conditions, *although it makes a useful alarm for high line* pressures.

During 65 experimental and clinical cardiopulmonary bypass *procedures, we have noticed fluctuations* of up to 100 mm Hg in the line pressures while the flow-rate remained constant. An occlusive setting has been used on a De Bakey pump on $^{3}/_{8}$ in or $^{1}/_{2}$ in internal-diameter 'Tygon' tubing to pump flows of 80–120 ml per kg per min through cannula 3–5·8 mm × 4 cm for procedures lasting up to two hours. Mean arterial blood-pressure was monitored in an internal *mammary or branchial artery by a pressure transducer* and ranged from 85 to 100 mm Hg, while line pressures ranged from 180 to 380 *mm Hg*.

In the laboratory the pressure drop is indeed due to the constriction of the cannula, but in the body an important factor is *vascular tone, especially as it* affects the artery directly adjacent to the cannula. Should the flow rise over approximately *3 litres per min in $^{3}/_{8}$ in internal-diameter* tubing, the change to turbulent flow will cause a disproportionately large increase in the pressure measured at the filter-chamber.

Hartford Hospital,
Hartford, Connecticut

I A SLOAN

INFLUENZA AND HEART-DISEASE

SIR,—I should like to refer to Dr Bourne and *Dr* Wedgwood's *paper*[1] on heart-diseases associated with influenza, and to Dr Apley's letter.[2]

We have observed a respiratory infection in a native male child of 2$^{1}/_{2}$ years which we considered as influenza because it occurred at the tail-end of an epidemic, and also because the *histopathological findings* in the lungs and heart suggested a viral infection. The child developed congestive heart-failure in the second week of his illness and died from it.

This might be of interest to people who have investigated the association of heart-disease with influenza, so we submit briefly the pathological report by Dr F H Vickers, of the University of Queensland.

Lung.—There is slight hæmorrhagic consolidation of lung parenchyma with probable œdema and a peribronchial mononuclear cell infiltration. *Patchy intra-alveolar phagocytes are seen in some fields* and the alveolar walls are rather thicker than normal suggesting the existence of mild *passive congestion*. As well there is evidence of a lobular pneumonia of indeterminate type.

Heart.—There is probable *hypertrophy* of most muscle fibres in

the heart and undoubted hypertrophy of some, so that the cardiac enlargement can be regarded as due to an increase in the bulk of the myocardial fibres and probably not due to œdema. This hypertrophy is accompanied by a slight but patchy mononuclear-cell infiltration most marked in the connective tissue around some of the blood-vessels and in the subserosa. The cellular infiltration is much more suggestive of a very mild myocarditis than an ischæmic lesion.

NATURAL HISTORY OF CAVERNOUS HÆMANGIOMATA

SIR,—It was sad to see Dr Simpson's valuable and careful analysis of hæmangiomata (Dec. 12) receive such hostile criticism in recent letters Dr Colin-Jones (Jan 2) writes airily of "misleading statistics", but cannot show that Dr Simpson's observations (or deductions) were in error He says "large numbers must be studied", but quotes with approval a series of 135 untreated cavernous lesions, while the paper he criticises deals with a slightly larger number He himself reports 814 cases which received X-ray therapy, he mentions that 200 required treatment "after the 5-year period" but he is curiously vague about the precise results He further confuses his own position by saying in one place "all are agreed that cavernous angiomas disappear in the course of time", but a little later he thinks "there is a great tendency to exaggerate the frequency"

Dr Simpson has in fact much well-informed dermatological opinion on his side, he also has the support of most plastic surgeons who, reluctant to carry out operative treatment which may give inferior results to those achieved by natural regression, still insist that the child is kept under close observation, they are thus in a position to intervene on rare specific indications. What plastic surgeons dread most in this context are the horrifying results which can follow the improper use of radiotherapy to "cure" non-malignant lesions in the young

The Queen Victoria Hospital,
East Grinstead

C R McLAUGHLIN

SIR,—It is apparent from the letters of Dr Colin-Jones and Mr Denis Browne (Jan. 2) that Dr Simpson has a hard task ahead if he wishes to convert all the treaters of cavernous hæmangiomata into non-treaters

I am sure that his policy of no-treatment is a wise one although it requires far more courage and persuasion on the part of the clinician to convince anxious parents that nothing should be done.

In Sheffield, for the past ten years, all the dermatologists have adopted a no-treatment policy for cavernous hæmangiomata. It has, therefore, been impossible for patients to leave one clinic and go to another where they would be treated. The radiotherapists, who include Dr Walter, the author of a controlled trial[1] of radiation and no-treatment in 1953, have carried out the same policy The only escape route for dissatisfied patients has been to the department of plastic surgery, and I understand that there has been no rise in the number of cases referred for operation during the ten years

The dermatologists and radiotherapists have watched spontaneous clearing occur in the great majority of the cases and they amount to some 200 hæmangiomata per year Resolution has been particularly striking in those cases which, by their size or site, give rise to the biggest problem and which present a formidable task for surgeon or radiotherapist. There are no extra hazards from awaiting spontaneous resolution and the cosmetic results are as good, if not better, than any form of treatment. There are dangers from radiation, for in the series of carcinomas of the thyroid reported by Wilson et al[2], 4 had received radiation for nævi around the neck. There is also no evidence that radiation does more than slightly speed up natural resolution

Dr Colin-Jones' remark that hæmangiomata are common in adults is difficult to understand since that is certainly not the experience in this area I believe that, as yet, no form of treatment is superior to spontaneous regression though it would be interesting to hear more of the results of Mr Denis Browne's early surgery

The Rupert Hallam Department
of Dermatology, Royal Infirmary,
Sheffield

I B SNEDDON

SIR,—It would be helpful if Mr Denis Browne would kindly clarify one or two points he has raised in his comments on the views of Dr Simpson and others who have worked along the same lines before him

With regard to the first statement that many dreadful disfigurements begin as tiny red spots either present at birth or appearing in the first month, could he produce evidence that the large disfiguring hæmangiomata do often grow from tiny strawberry marks? I have watched for the development for years and have never seen it happen, assuming therefore that the deeply situated hæmangiomata must arise subcutaneously Be it noted that only one type of hæmangioma is discussed in Dr Simpson's paper, "port wine" and systematised nævi being rigidly excluded

Next he states categorically that in their earliest stages hæmangiomatous nævi are quite invariably dismissed as trivialities, but he does not say by whom Does he mean parents, general practitioners, or dermatologists, or all three? The long and meticulous follow-up studies by dermatologists to which he refers in his opening remarks indicate at least that some dermatologists have accepted these nævi as a very serious responsibility

Finally he says that while no early case has ever been referred to him by a general practitioner, "in spite of his preaching that a growing red spot on a baby's face is a surgical emergency", he has picked up a few and treated them. The results, he says, suggest that the process of regression can be started very early in the growing stage by producing inflammation in the abnormal tissues Could he possibly enlarge on this experience and tell us what he does? Most of the dermatologists have discarded diathermy, cauterising, and the injection of chemical substances because they, to whom these cases are referred in numbers by practitioners, have found such methods unsatisfactory. It is precisely this fact that has prompted the natural-history studies during the past twenty years Freezing for small strawberry nævi is evidently acceptable to some, but the outlook in these nævi when not treated has long been known to be so good that many think it wiser to let well alone. Few will use any kind of radiotherapy in infants except when it can hardly be avoided. Is there something else about which we have not heard?

London, W 1

G B DOWLING

SIR,—The essential point at issue in this discussion is surely a simple one—is there any real risk involved in treating all cavernous nævi with X-rays or thorium X, because if there is no risk, it is surely the best policy to give all affected children the benefit of treatment until the day when it is possible to distinguish at an early stage between those lesions which are likely to resolve spontaneously and those which will persist

---

[1] Walter, J *J Fac. Radiol* 1953, 5, 134.

[2] Wilson G M., Kilpatrick, R., Eckert H., Curran, R C., Jepson, R. P., Blomfield, G W *Brit med J* 1958, ii, 929

I have been irradiating nævi for nearly twenty years, having initially used what would now be regarded as a rather high dose of 600–800r at 100 kV, repeated after three months, but I have yet to see or hear of any permanent ill effect among my treated cases, numbering over 1000, including those treated in association with Dr Colin-Jones In a confined community such as this, one would expect to be made aware of any untoward sequelæ of treatment, and colleagues would not continue to refer cases were they not completely satisfied

There is at present a swing away from the use of radiotherapy in non-malignant conditions, particularly in children, and while it is wise to keep in mind the hazards attending the irradiation of living tissues, few methods of treatment contain no possibilities of causing damage if improperly used, and it would be a great pity if patients of any age were to be deprived of beneficial treatment because of unjustified fears engendered by propaganda The dosage given to a child with a nævus is less than would result from many X-ray examinations, measured as total-body dosage, and the local dose used now, of the order of 400r at 60–100 kV on small fields, has not shown any late changes in the skin, hair, or bone

May I conclude that we should continue to use our clinical judgment in dealing with nævi and that we should not be swayed against active treatment by doubtful hopes of natural resolution

Hove E MILLINGTON

SIR,—The article by Dr Simpson and the subsequent correspondence indicate the confusion which is caused by the terminology of hæmangiomata

When Dr Simpson talks about " cavernous hæmangioma " he is presumably referring only to the common " strawberry nævus ", a lesion which is typically confined to the skin, and we are in entire agreement with him that these lesions will always regress spontaneously and that no treatment is necessary Since they always disappear spontaneously, it follows that any form of treatment will be credited with good results It seems unlikely that injection of sclerosing substances, treatment by carbon-dioxide snow, and similar methods will result in harmful sequelæ, but in view of the late, serious, and quite unpredictable consequences of treatment by radiotherapy, it seems to us that the use of such a powerful agent is highly undesirable and can be justified only in the most exceptional circumstances

We cannot agree with Dr Colin-Jones that " strawberry nævus " is commonly seen in adults None of the surgeons in this centre has ever seen such a lesion, although we have seen many other types of angiomata in adults If Dr Colin-Jones has failed to distinguish the different types of hæmangioma, the results of his treatment are impossible to evaluate

We strongly advocate that the term " cavernous hæmangioma " *should not be used for these common* skin lesions, but that they be described by the homely but unmistakable term " strawberry nævus"

ATRIAL FIBRILLATION IN CARCINOMA OF THE LUNG

SIR,—The association of arrythmia with carcinoma of the lung has prevously been noted, but the following case seems worth recording to stress the importance of what appears to be a little-known manifestation of the commonest form of cancer [1,2]

A man of 55 complained for one year of dizziness on exertion, associated more recently with attacks of regular palpitations, beginning and ending suddenly He admitted to cough and pain in the shoulder for the previous fortnight but had no other significant symptoms He had atrial fibrillation, with an apex rate of 120 and a pulse deficit of 16

The chest showed flattening and diminished movement in the left upper zone, with an impaired percussion note, diminished breath sounds, and a persistent localised rhonchus There were no other significant physical findings

A clinical diagnosis of bronchial carcinoma was made on the basis of the association of signs of left upper-lobe collapse with atrial fibrillation

Radiography showed a large left hilar mass with upper lobe collapse and a trace of fluid at the left base Tomograms demonstrated almost complete occlusion of the left upper-lobe bronchus Electrocardiography showed uncontrolled atrial fibrillation Repeated sputum examination for malignant cells was negative

An attempt to restore sinus rhythm with quinidine succeeded only for a few hours, after which ventricular tachycardia supervened It was therefore decided to slow the ventricular rate with digoxin

His general condition deteriorated rapidly and he developed massive hepatomegaly and bloodstained ascites A further E C G before death showed that runs of atrial extrasystoles had developed, with varying PR interval

He died seven weeks after first being seen Necropsy confirmed the diagnosis The growth arose in the left main bronchus and invaded the left atrium and compressed the left pulmonary vessels The heart was otherwise normal There were massive deposits in the liver

There are two especially interesting features of this case

(1) The fact that atrial fibrillation was the presenting feature

(2) The fact that apart from the fortnight of cough and shoulder pain before attending outpatients, there were no respiratory symptoms throughout the course of the illness

Since this patient was seen, I have seen a further case in which atrial fibrillation arose in a 75-year-old man with signs of left lower-lobe collapse He deteriorated rapidly, and necropsy revealed a carcinoma of the lung which had invaded the pericardium and myocardium There was no coronary atheroma

My thanks are due to Dr R A Hickling for his encouragement and for his permission to publish this account of his patient I should also like to thank Dr H P Clarke for making it possible for me to visit the patient at home

London, N 10 W L ASHTON

DIURNAL FLUCTUATIONS OF PLASMA FIBRINOLYTIC ACTIVITY

SIR,—Readers of the articles by Buckell and Elliot [1,2] may be interested in the following observations

The diurnal fluctuations of fibrinolytic plasma activity were observed independently in our laboratories, and first described two years ago [3–6] The fluctuations of fibrinolytic activity were tested on diluted oxalate plasma and euglobulins clotting with Ca++ addition and, furthermore, on thrombin clots of oxalate euglobulins, which do not form intrinsic thrombin Samples of citrate-thrombin, free of plasma, were used The daily fluctuations of fibrinolysis were most pronounced in the thrombin clots of oxalate euglobulins The titre of antifibrinolysin did not fluctuate adequately in samples of plasma and sera taken during the day The antifibrinolysin was tested on a system consisting of bovine plasma, fibrinogen, and citrate-thrombin The titre was found to vary from 50 to 87 arbitrary units in samples of plasma taken in the morning and from 46 to 88 in samples taken at the height of the fibrinolytic activity The respective figures in serum were 51 to 76 and 43 to 70 units Thus, changes of the antifibrinolytic titre do not seem to be the cause of the diurnal fluctuations of fibrinolysis

---

[5] Siwińska-Kotschy, M , Głogowska, I *ibid* p 533

[6] Kowarzyk, H , Kotschy, M , Głogowska, I *ibid* 1959, 13, 315

The highest activity of fibrinolysis was comparable to that observed in an emergency reaction after adrenaline and in a hypoxæmic state at low air pressure. The diurnal fluctuations are a stress reaction and they vary from person to person and in the same individual from day to day The diurnal fluctuations do not appear in young males confined to bed—e g , with fractures

T.A.M. (tosyl-L-arginine methyl ester HCl) esterase activity of plasma and serum does not fluctuate correspondingly

Diurnal fluctuations may mask the effect of alimentary lipæmia on fibrinolysis[7] When comparing small groups of persons examined with the euglobulin and diluted plasma-technique at fixed hours of the day, one fasting, the other one after a fat meal, no significant differences of fibrinolytic activity were found between the lipæmic and control groups, the diurnal fluctuations of lysis time being invariably superimposed on the presumed lipæmic effect Our main interest was in the activating mechanism of fibrinolysis, and no further attempt was made to verify the effect of lipæmia on fibrinolysis

The fibrinolytic activity of globulins from diluted and acidified human plasma is potentiated by the process of thrombin formation[8,9] The time of fibrinolysis is shorter in spontaneously clotting euglobulins than in the thrombin clot of the euglobulins not forming intrinsic thrombin The time of lysis, in our operative conditions, averaged 210 and 450 minutes respectively In stress, the time of lysis of thrombin clots is decreased to about 160 minutes In the state of increased fibrinolysis, however, the generation of thrombin does not induce a further rise of fibrinolytic activity Thus, the fibrinolytic activity developed in stress obscures the fibrinolytic activity related to thrombin formation

The data so far available support the view that a uniform activating mechanism acts in vivo in the fibrinolytic stress reaction and in vitro in thrombin-forming fibrinolytic systems

HOTELS OR HOSPITALS?

SIR,—I read with interest the article by Mr Stallworthy (Jan 9) on the subject of " hotel " accommodation following operation Thanks to a generous benefactor, it was possible in June of last year to open a " continuation " unit attached to Kilmarnock Infirmary It is hoped to publish at the end of a year's work of this annexe a full report of the economic and clinical advantages

The building, now called Torrance House, is a former sanatorium, and has been converted into very comfortable " hotel " accommodation with adequate rest and recreation rooms and dining-rooms Beds are available for 44 patients, at present allocated between general surgery (28) and general medicine (16) The 28 surgical beds are filled from 60 surgical beds in the parent hospital, which is within ten minutes' distance by ambulance Patients are transferred to Torrance House as soon after operation as it is thought that they are fit to walk from the sitting-rooms to the dining-rooms Thus hernia repairs, appendicectomies, and hæmorrhoidectomies are normally transferred on the second or third postoperative day, and gastrectomies, vagotomies, and cholecystectomies on the fifth day There is no routine transfer, the fitness of the patient for the annexe is assessed on the day before the transfer The patients are transported by ambulance from the parent hospital, and throughout their stay in the annexe they wear their own clothes

No medical staff is resident in the annexe, but a direct telephone line to this parent hospital means that a house-surgeon is on immediate call Nursing staff consists of one matron, two sisters, two full-time and two part-time staff nurses, two full-time auxiliary nurses, and four part-time assistant nurses

During the short time that Torrance House has been in action the advantages set out by Mr Stallworthy have become apparent In the first six months 620 patients were transferred to the surgical beds from Kilmarnock Infirmary with the result that the general surgical waiting-list has come down in that time from 460 to 310 after years of being static or rising The comfort, quietness, and access to gardens is appreciated by the patients, and early return to complete activity is hastened It is surprising how well a fifth-day gastrectomy can play billiards!

No serious disadvantages have been encountered, but a certain self-discipline is required by those in charge of beds in the " hotel " As far as Torrance House is concerned, it has been written into the constitution that the maximum stay for patients is three weeks—this to prevent any temptation to use beds for chronic sick. We have made it a routine here for all surgical patients in the annexe to be seen daily by a consultant together with the registrar or a house-surgeon. This is necessary, not only for the purpose of clinical supervision, but in order to avoid giving the patients the impression that they are being " dumped " out of the main hospital

The Infirmary,
Kilmarnock

GAVIN J RALSTON

SIR,—How heartening to see in last week's *Lancet* a really imaginative article on the future planning of a hospital and home-care service There are a good many nurses who also believe that the future of our health service will lie in acute central hospitals for the individual who needs and must have hospital care, plus convalescent aftercare units run on hotel lines, and a really well-organised, well-staffed domiciliary medical and nursing service

One visualises " flying-squads " of nurses and doctors visiting people in their own homes, doing dressings, treatment, and so on The " squads " would be based on the local authority What a wonderful opportunity to train nurses and doctors! At present one of the most common criticisms levelled at our nurse-training by other countries is that British nurses " only nurse in hospital ", a criticism that cannot be denied but with the kind of service envisaged, trainee nurses and medical students alike would get immensely valuable training in caring for people in the ordinary social setting of their homes a broadening and educational experience we could all do with early in our career The acute centres would, of course, deal with all conditions requiring hospital care, for whatever cause Again, the ideal training situation, where the student can have experience of all human ills under one roof—a really comprehensive training, with plenty of chance to specialise later

For so long now I have thought about this idea as a sort of unattainable pipe-dream, regarded as fantastic if expressed, that it is really exciting to see it has already taken shape in other minds, though perhaps it is a little ironical that it has taken us about two hundred years to persuade people that hospital is the best place to be ill in, and now that this idea seems to have been well and truly sold to the suffering public there are signs of a move to re-educate them to prefer to be ill at home Somehow I think the process is likely to take less time

Tooting Bec Hospital,
London, S W 17

Obituary

WILLIAM ROBERT FEARON

M A, M B, Sc D Dubl, F R I C

Professor Fearon, who held the chair of biochemistry in the University of Dublin and was a member of the Irish Senate, died on Dec 27 at the age of 67

His father, the Rev William Fearon, of Kells, died when he was a child and he was brought up by his mother From St Andrew's College, Dublin, he entered Trinity College in 1911 and started his medical studies soon afterwards But he was such a versatile student (winning with equal ease medical scholarships, the Purser medal in physiology, and the vice-chancellor's prize in English verse, and taking an honours degree in the natural sciences) that he did not finally qualify till 1929 Meanwhile he had spent two years with an exhibition at Emmanuel College, Cambridge In 1921 he was appointed to a fellowship at Trinity College, Dublin There, though his chief duty was teaching physical chemistry, physiology, and biochemistry, he also gladly gave lectures in logic and examined in that subject But the influence of Werner in Dublin and Gowland Hopkins in Cambridge had already determined him to make biochemistry his chief interest He was appointed lecturer in 1921, and in 1934 a chair was created for him In the same year the first edition of his well-known *Introduction to Biochemistry* appeared Even with growing academic responsibilities his interests in the arts did not slacken, and his play *Parnell of Avondale* was successfully produced at the Abbey Theatre in 1937

Some of Fearon's earliest biochemical work was related to urea, which was Werner's special interest, and to vitamins But it was not long before another side of his nature began to express itself in his work He was early elected honorary professor of chemistry to the Royal Hibernian Academy, and his love of colour, as of the artistic, combined to make him an ideal choice In his scientific work the charm which colour held for him began to express itself in the development of a series of colour reactions for the identification of a wide range of compounds of biological interest

In 1943 he was first chosen by the university electorate as their representative in the Irish Senate

R A Q O'M writes

"Of his election to the Senate, Fearon was very proud and, curiously, this honour provided him with more pleasure and satisfaction than many others which he had won during his distinguished career The university electorate continued to the end to return him and, in the special circumstances which govern this election, his repeated return signified that his former students supported him with their first preference votes almost to a man Of course, he drew support from other sources as well, but no doubt the memory of his inspired teaching must have remained to prompt them as they marked their voting-papers His lectures were memorable not alone for their scientific content but for the beauty of the language and the clarity of expression, enlivened by artistic, musical, theatrical, and poetic reference, with which they were delivered, and when he spoke in the Senate his audience was likewise held Standing at Fearon's graveside an elder of the House, well tried in politics, said, 'He could make a speech He had a nice wit and a sense of irony, too'

"His wit and irony, never malicious though often happily pointed, were a charming asset to Fearon at the table or on the platform He was much sought after on such occasions as opening meetings of societies or when the time had come to lionise the distinguished visitor He appreciated good food and wine, but as time went by he became more difficult to entice to the festive occasion Great was the reward of success in such enticement, however, for an evening in his company never flagged Even the chance and seemingly aimless remark of the least important of the guests was likely to be taken at more than its value and built by him into a subject for serious consideration in a happily light vein For it was one of his characteristics that he was always ready to listen to others, to see good in their often faltering thoughts and gently to amplify them so that they rapidly grew, like a tree, to have many branches

"Fearon remained a bachelor He lived with his mother, to whom he was greatly attached, and who died only a few years ago His home life was simple, though he had one inclination to extravagance—in his cars In the 'twenties he could be seen as the sole occupant of a long Lancia, later of a Bentley, and in the final years, as befitted his Senatorial rank, of a Rolls Towards the end it was apparent that he was becoming dissatisfied with the crudities of modern life and in particular felt unhappy about the decline in manners in our times His was a generous, courteous, and upright nature, and he was incapable of the rudely aggressive or of the plausibly dishonest For him 'the larger heart, the kindlier hand'"

Dr J E. A UNDERWOOD

R E S writes

"The Medical Officers of Schools Association owes Dr Underwood a particular debt He realised that, though doctors at public schools had for a long time usually occupied the important offices, the association had the welfare of all types of boys and girls at heart He was the first senior official of the Ministry of Education to take an active part in our discussions and the first to become president (in the 68th year of our foundation) From 1952 to 1953 he presided with great dignity and we came to know that behind his humility lay great knowledge especially of the handicapped child His name will be remembered in many ways but it will live chiefly for the Underwood report on the maladjusted child"

Public Health

Safety Code for Use of Ionising Radiations

REVISIONS to the draft code, issued in July, 1957, for the protection of workers engaged in operations involving the production, emission, or use of sealed sources of ionising radiations are contained in the second preliminary draft of special regulations[1] published this week

The original draft included a general invitation to industry, associations, and others concerned to make comments on the proposed regulations, and many suggestions were received and amendments arising from the observations have been included in the new draft

The schedule specifying the maximum permissible radiation doses has been remodelled taking account of the views of the Medical Research Council and the revised recommendations of the International Commission on Radiological Protection It has been simplified by restricting it to certain ionising radiations which are ordinarily met with in industrial work with sealed sources There are new provisions dealing with tests for personal exposure and medical supervision, with the examination of persons employed in the processes, and the procedure to be adopted where workers employed in the processes move from one factory to another Fuel elements used or intended to be used in a nuclear reactor will not be covered by these regulations, which also exclude from their application ionising radiations used for medical purposes in factories or rooms specially set apart Comments on the new draft are requested by April 15

Arsenites in Agriculture

Mr John Hare, Minister of Agriculture, Fisheries, and Food, has announced that the use of alkali arsenites in agriculture is to be restricted Speaking at Wells on Jan 6, he said

"The potential risks here are particularly wide because of the large number of people involved and the danger to cattle The Advisory Committee on Poisonous Substances, which deals with agriculture and food storage, recommended that their use should be voluntarily banned agreement has now been reached that the manufacture of alkali arsenites for use in this country as haulm destroyers and weed killers shall now stop, and that after this year's potato harvest the agricultural and ancillary industries will withdraw these arsenites from agricultural use This voluntary ban will not apply to sheep or cattle dips, or to the use of lead arsenate on fruit trees"

---

Notes and News

RESEARCH ON INTERFERON

A SUBSTANCE "with many of the properties of a wide-spectrum viral antibiotic", interferon was discovered at the National Institute for Medical Research during study of the virus interference phenomenon.[1] In his investigations with colleagues, Dr Alick Isaacs has shown that it is a protein, of low toxicity to tissues, which is apparently non-antigenic and able to inhibit the growth of a large variety of viruses. Two papers on its action appeared in our columns last September.[2]

Before the possible therapeutic use of interferon could be studied, much basic research on its properties had to be done, but a stage has now been reached when the development work that must precede therapeutic trial can be undertaken. So as to get an answer quickly, the Medical Research Council have entered into an arrangement for collaborative research with three firms in the pharmaceutical industry—namely, Glaxo Laboratories Ltd., Imperial Chemical Industries Ltd., and the Wellcome Foundation Ltd.—the National Research Development Corporation also being a party to the agreement. The work covered by the agreement includes research into the pilot-scale production of interferon required for research purposes and studies of its effect in experimental virus infections of animals. Whether it is used in therapeutic trials in human beings will depend on the results of these experiments.

A NEW INSTRUMENT

THE official existence of the new organisation and methods unit of the Ministry of Health is a sign that work study has been accepted as an effective aid to the administration of the National Health Service. Skill in using new tools usually increases with practice, and in work study the relatively close-knit hospital services will probably be easier terrain than, say, the diffuse and often highly individual arrangements hopefully covered by the orderly title of "general medical services". The National Association of Hospital Management Committee Group Secretaries have, therefore, been considering work study in the hospital service.[3] They are firmly in favour of its adoption because they believe that properly applied it may save some money (though not perhaps so much as expected, for it will sometimes lead to redeployment rather than reduction of resources) and that it will also encourage the staff to take a more informed interest in their work and often improve their working conditions. It will provide badly needed facts on priorities and needs for capital development.

The report suggests that one of the common objections to work study—that it impairs staff morale—is caused by faulty application. With tact and the right approach this difficulty should usually be avoided. Nor should work study properly conducted bring a risk of reducing services to patients, for a rational assessment of the activities of a hospital should recognise such small acts as cups of tea and reassuring talks with patients and relatives as part of a good nurse's true duties. On their frank appraisal of these difficulties is based the Association's recommendation that the most suitable subjects for work studies, at least at first, are the indirect services to the patients, such as laundry and catering, and the nonclinical organisation of other parts of the hospital, such as appointment systems or records. Judging by the reports already issued this policy has been accepted by the Ministry's unit.

Difficulties would also be avoided, the Association suggest, if the study was conducted from within the hospital rather than from without, by someone who understands the background and is familiar with medical and nursing problems. In their view it should be done at H.M.C. level, and all senior hospital staff members should attend short courses on work study, and selected officers, of at least senior administrative grade, who would actually conduct the studies should attend a three-month course. It will be interesting to see how other hospital authorities, such as regional hospital boards and the Ministry, react to this last suggestion. Certainly much of the rest of this thoughtful report will win their approbation.

AMATEUR BOXING

A HANDBOOK lately issued by the London Amateur Boxing Association[1] is short but not everywhere clear or to the point. What is clear, however, is that the Association considers that the risks of boxing are not serious. The statement that "boxing represents the only opportunity in man of observing repeated head injuries in an almost experimental setting" presumably implies that the "experiment" should continue until the effect of these injuries on the brain can be fully and accurately assessed. But is this "experiment" either justifiable or necessary? Is there not overwhelming evidence that even trivial head injuries can cause serious brain damage? The boxer is exposed to injuries which are deliberate, repeated, and often severe enough to cause loss of consciousness. If the nature and extent of the damage they cause has not yet been accurately assessed, should we not, nevertheless, give the brain the benefit of any doubt? Enlightenment of the public on the dangers of boxing can come only from the medical profession, and an authoritative statement by a detached body of medical experts would do much good.

NUTRITION IN AFRICA

IN Angola in 1956, the Commission for Technical Cooperation in Africa South of the Sahara held a conference on nutrition. The second volume of the report of this conference,[2] written in French, English, and Portuguese, deals with improvements of national diets with protein-rich foods, agriculture and nutrition, public-health services and education in nutrition, treatment of ariboflavinosis in schoolchildren, the digestibility of cassava, and many other subjects. Though the many authors and different styles of presentation make it difficult to read, it contains much valuable information, and a small but useful index makes it a good reference for nutritional problems in Africa.

University of London

Dr G. V. R. Born, research officer at the Nuffield Institute for Medical Research and departmental demonstrator in pharmacology in the University of Oxford, has been appointed to the Vandervell chair of pharmacology tenable at the Institute of Basic Medical Sciences.

Dr Born qualified M.B. at the University of Edinburgh in 1943. Subsequently he entered the R.A.M.C., in which he worked as a pathologist. He was demobilised in 1947, and the following year he went as a Medical Research Council student in research methods to Oxford, where he studied the bacteriolytic enzymes of streptomyces. From 1951 he was for two years a member of the Council's scientific staff, working in the toxicology research unit at Carshalton. He returned to Oxford in 1953. He graduated D.PHIL. at Oxford in 1951, and M.A. in 1956. Dr Born's published work includes papers on smooth muscle and on blood platelets, and a chapter on the effects of injury on metabolism in Florey's *General Pathology*.

Dr D. L. J. Bilbey, assistant professor of anatomy in the University of Toronto, has been appointed to a readership in anatomy tenable at King's College.

Dr R. M. H. McMinn, lecturer in the University of Sheffield, has been appointed to a readership in anatomy tenable at King's College.

University of Liverpool

A symposium on general practice and psychiatry will be held on Saturday, March 26, at 10 A.M., in the University New Medical School, Ashton Street, Liverpool. Tickets may be had from the director, Department of Studies in Psychological Medicine, 77, Bedford Street South, Liverpool, 7.

University of Birmingham

Dr. R. F Fletcher has been appointed lecturer in medicine

University of St. Andrews

Dr John Simpson has been appointed senior lecturer in public health and social medicine in Queen's College, Dundee

Royal College of Physicians of London

On Tuesday and Thursday, Feb 2 and 4, Dr L G Norman will give the Milroy lectures He will speak on the medical aspects of the prevention of road accidents On Tuesday and Thursday, Feb 23 and 25, Prof D E Denny-Brown will give the Croonian lectures He will speak on diseases of the basal ganglia and their relation to disorders of movement All the lectures will be given at 5 P M at the college, Pall Mall East, S W 1

Royal Faculty of Physicians and Surgeons

At a meeting on Jan 4, with Mr Arthur Jacobs, the president, in the chair, the following were admitted to the fellowship of the faculty

Majid Ali Jafri *qua physician*, Mohamed Magid Ismail Fakhr, C N Hudson, D G Jones *qua surgeon*

College of General Practitioners

Public Welfare Foundation Prize —Six prizes (£40 each) are offered to encourage senior medical students to study the diagnosis and management of patients in the setting of general practice Particulars may be had from the secretary of the college, 41, Cadogan Gardens, London, S W 3 The closing date is May 1

International Hospital Federation

Dr J C J Burkens, medical director of the Oude en Nieuwe Gasthuis, Delft, Holland, has succeeded Captain J E Stone as hon secretary and treasurer of the Federation The secretariat remains in England at 34, King Street, London, E C 2

Medical Costs in South Africa

Dr Albert Hertzog, the South African Minister of Health, has announced the appointment of a commission to inquire into the factors responsible for the high cost of medical services and of medicines and into ways in which these costs can be lowered The Minister said

> " Families in the middle-income group are especially hard hit On the one hand they cannot, as in the case of the less privileged, receive free medical treatment, and on the other hand they are not financially in a position to spend large sums of money on treatment It often happens that, because of the serious illness of one member, a whole family is crippled financially for years Others again neglect their health with tragic results because they cannot manage the high expenditure "

Professor J A B Gray will give his inaugural lecture on Tuesday, Feb 23, at 5 30 P M at University College, Gower Street, London, W C 1 He will speak on the place of physiology in university education

The Polar Medal has been awarded to Dr R L Willing for service as medical officer to the Australian National Antarctic Research Expedition to Mawson, 1957

Dr P K Basu has been appointed the Stapells director of ophthalmic research in the University of Toronto

The Biochemical Society will hold a meeting on Saturday, Jan 23, at 10 A M at the London Hospital Medical College, Turner Street, E 1

The closing date for entries for the Jean Hunter Bequest of the Royal College of Physicians of Edinburgh (Advertisers' Announcements, Jan 9, p 37) has been advanced to June 30, 1960

The General Medical Council has published the third edition of their *List of Approved Hospitals and Institutions and Recognised House Officer Posts* Copies (7*s* 6*d*) may be had from the registrar of the Council, 44, Hallam Street, London, W 1

CORRIGENDUM *Resistance to Ketosis in Obese Subjects* —In the paper by Professor Kekwick and his colleagues (Dec 26) a sentence near the bottom of column 2 on p 1158 should read " Blood leaving the brain has a respiratory quotient of 0 97 and the rate of utilisation of glucose is about 5 5 mg per minute per 100 g brain "

RESTENOSIS OF THE MITRAL VALVE

AN ACCOUNT OF FIFTY SECOND OPERATIONS

J R Belcher
M.S Lond., F.R.C.S
SURGEON, LONDON CHEST HOSPITAL,
ASSISTANT THORACIC SURGEON, MIDDLESEX HOSPITAL, LONDON, W 1

There have been few reports concerning restenosis of the mitral valve, although many second and even third operations must have been performed. This paper gives an account of the reexploration of 50 mitral valves

Material

The 50 operations have been done since 1954, and the 12 cases reported in 1958 are included in this number 31 patients had their first operation done by me, and the remaining 19 by other surgeons

The 31 personal cases were from a series of 294 in which the mitral valve had been explored and the patients followed up for more than a year 1 patient from this number has been successfully operated on for a second time in New Zealand.

Incidence

There has been a tendency to use the term " restenosis " only for those cases in which an adequate valvotomy has previously been performed (Bailey and Goldberg 1957, Patterson and Marshall 1959) If this is accepted, another term is required for cases in whom narrowing of the orifice follows an inadequate valvotomy, this narrowing causes deterioration and requires treatment quite as much as that which may follow an adequate valvotomy For this reason, the terms " true " and " false " restenosis are retained (Belcher 1958)

" True " restenosis was defined as that which might occur when at least one commissure had been fully opened at the first operation. In these cases the commissure concerned could often be opened with the finger, and " true " restenosis can be confidently diagnosed when this is so In other cases the assessment at the first operation had sometimes been undoubtedly optimistic, but in all those in which a " good " or " fair-to-good " operation was recorded on the first occasion when restenosis occurred, it has been classed as " true " restenosis

The much commoner *" false " restenosis* was defined as that which might follow inadequate commissurotomy In these cases, although considerable improvement often followed enlargement of the orifice, the cusps remained in apposition. As a result the valve orifice was likely to decrease in size again, and so lead to the return of symptoms

Using these definitions, the series comprised 17 examples of " true " restenosis, 29 examples of " false " restenosis, and 4 cases in which no restenosis was found at the second operation Of the personal cases, 17 had had inadequate operations on the first occasion, and therefore had " false " restenosis In the remaining 11, at least one commissure had been fully opened at the first operation, and in some of these it could be readily reopened with the finger these were examples of " true " restenosis (table I)

TABLE I—FINDINGS AT SECOND OPERATION

Restenosis at second operation	First operation		Total
	Personal cases	Other surgeons' cases	
' True '	11	6	17
" False "	17	12	29
None	3	1	4
Total	31	19	50

The commissurotomies in the first operations in the personal series were classified as follows those in which both commissures were fully opened as " good " those in which the split was a little less complete as " fair-to-good " those in which only one commissure was fully opened or in which neither was opened completely as " fair " and those in which dilatation only was achieved as " poor " (fig 1)

The incidence of restenosis and of late deaths in each of these groups is shown in table II These totals exclude those patients who died at operation and those in whom exploration revealed dominant mitral incompetence

TABLE II—RESTENOSIS AND LATE DEATHS RELATED TO INITIAL COMMISSUROTOMY

Initial commissurotomy	No	Restenosis	Late deaths
" Good '	86 (*29*%)	0	4 (*5*%)
" Fair-to-good '	135 (*46*%)	7 (*5*%)	7 (*5*%)
' Fair '	61 (*21*%)	16 (*26*%)	5 (*8*%)
' Poor '	12 (*4*%)	8 (*66*%)	2 (*16*%)
Total	294	31 (*11*%)	18 (*6*%)

The incidence of " false " restenosis is only an index of the number of unsatisfactory operations in any given series All save 2 of those who had "poor" operations in the personal series either have had second operations or have died. No commissurotomies in this class have been done since 1955 when the transventricular technique was introduced.

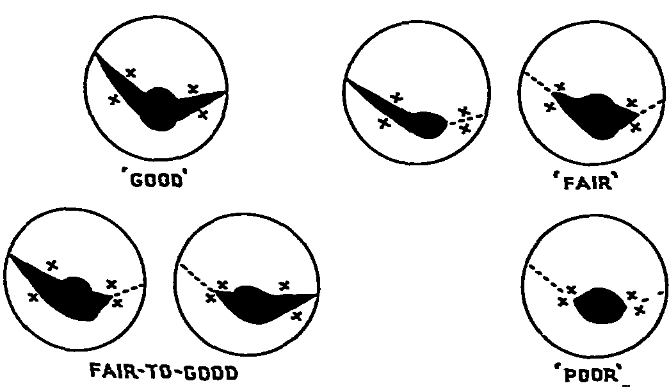

Fig 1—Grade of commissurotomy

Where the valvotomy was thought to have been " fair ", the proportion of patients submitted to second operations has now reached 26% (table II), but fig 2 shows that the longer the follow-up the higher the rate of restenosis has been (table III) the rate amounts to 37% of those operated on more than five years ago It therefore seems likely that the number of patients in this group requiring a second valvotomy will rise as years go by Since the introduction of the transventricular method by

TABLE III—NUMBER OF CASES OF RESTENOSIS (R S) RELATED TO NUMBER OF FIRST OPERATIONS, GRADED FROM " POOR " TO " GOOD "

Year	" Poor "		" Fair "		" Fair-to-good "		" Good "	
	No	R S	No	R S	No	R S	No	R S
1952	2	1	5	4	1	0	1	0
1953	4	3	10	4	4	1	7	0
1954	5	4	9	1	30	1	8	0
1955	1	0	8	3	36	4	19	0
1956			9	2	28	1	21	0
1957			15	2	19	0	20	0
1958			6	0	16	0	10	0

Logan (see Logan and Turner 1959) a lower proportion of valvotomies have been considered " fair " in my hands, and it is therefore hoped that the incidence of " false " restenosis will be much less in the future

The incidence of restenosis in the patients in whom the commissurotomy was " fair-to-good " has remained fairly steady at 6–8% (fig 2) This suggests that the mechanism of " true " restenosis may be different from the gradual narrowing of apposed cusps probably responsible for " false " restenosis On the other hand, no second operation has yet been required in my series where the commissurotomy was considered to have been " good " It is therefore still not certain whether " true " and " false " restenosis are different in essence or in degree

It has been suggested that restenosis is due to reactivation of the rheumatic process (McKusick 1955), but no further evidence to support this view has been forthcoming Both Bailey and Goldberg (1957), who had 1 case of restenosis due to reactivation in their first 1000 valvotomies, and Patterson and Marshall (1959) are of the opinion that a cause other than rheumatism must be sought In only 1 of the 50 cases presented here was there any suggestion of reactivation

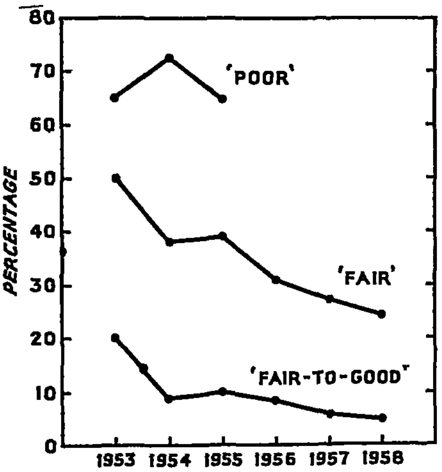

Fig 2—Proportion of patients graded according to results of initial commissurotomy, requiring second operations, by years

Diagnosis

As in cases of primary mitral stenosis, the diagnosis rests on the assessment of the history, of the physical signs, and of special investigations In cases of restenosis, however, more information is available The detailed account of the first operation is all-important, and the postoperative history is often helpful

CLINICAL PRESENTATION

Of the 50 patients 9 were men and 41 were women Their average age was 37 years with extremes of 22 and 51 There appeared to be no difference in the history of those patients with " true " and those with " false " restenosis, except that the average interval between the first operation and the return of exercise tolerance to the preoperative level was shorter in " false " restenosis (25 months as against 34 months)

The return of symptoms, often heralded by " bronchitis ", was usually gradual, but in 9 patients the deterioration was quite sudden, in 4 this sudden reappearance of symptoms could be attributed to the onset of atrial fibrillation, but in others there was no obvious cause (20 of the patients were in sinus rhythm at the time of their original operation, the remainder were fibrillating)

PREOPERATIVE HISTORY

The extent of the improvement achieved by the first operation is important in the diagnosis of restenosis The best guide to the result of any operation for mitral stenosis is the efficacy of the commissurotomy If therefore the first valvotomy was adequate and yet little improvement has resulted, then almost certainly some other factor, such as bronchitis or tricuspid-valve disease, is playing an important part and the diagnosis of restenosis should be made with caution

Secondly, if the degree of stenosis found at the first operation was considerably less than that which might have been predicted from the disability, then again a diagnosis of restenosis may be incorrect, particularly if little improvement was achieved by the first operation

Lastly, if a good result with much improvement in exercise tolerance followed the first operation, and this was followed by deterioration, restenosis is almost certain to be the cause

DESCRIPTION OF FIRST OPERATION

Efficacy of the Split

The most important factor when a second operation is being considered is the description of the first commissurotomy (fig 1) If it was " poor ", a second operation is almost certain to be required eventually If it was " fair "—particularly if neither commissure was opened beyond the critical point of tendon insertion—restenosis is likely If, on the other hand, adequate valvotomy was recorded (" good " or " fair-to-good ") then, if restenosis occurs, it is " true " restenosis, and this is uncommon Other causes of failure must be sought before the diagnosis is made

Mitral Incompetence

In some cases of mitral-valve disease the importance of regurgitation may be difficult or impossible to assess, but, once the valve has been explored, there is less uncertainty if an accurate description of the amount of regurgitation at the end of the first operation is available In the 11 personal cases in this series in which this problem arose, it was found that, although in 3 grade-I incompetence at the end of the first operation had increased to grade-II, and in 3 minor incompetence had appeared, in none had the regurgitation become sufficiently severe to be significant In 1 case grade-I incompetence had apparently disappeared In the remainder the grade of incompetence was unaltered

The increase from grade-I to grade-II incompetence is easily accounted for by error of observation Accurate grading of regurgitation is difficult, particularly when there is some hypotension immediately after valvotomy Grade-I incompetence may also be missed at this time

The grading was done as follows if the reflux was just palpable it was graded as I if it was easily palpable but was not thought to be significant, as II, if severe, as III, if gross as IV (Belcher 1956)

These findings are important, as they suggest that mitral incompetence is unlikely to increase significantly in the years following a valvotomy, and therefore that the description of the regurgitation at the end of the first operation is valuable when the significance of signs of incompetence is being assessed If little or no regurgitation was reported at the end of the first operation, it is most unlikely to be responsible for symptoms

Thus the detailed report of the first operation is of paramount importance when a diagnosis of restenosis is being considered

PHYSICAL SIGNS

Ideally the diastolic murmur is almost abolished by a good valvotomy Hence were a long loud diastolic murmur to reappear after its abolition by the first operation, a diagnosis of restenosis would be likely In this series, however, this occurence was recorded only once among the cases of " true " restenosis, and in none of those who had inadequate valvotomies was there a short murmur after their first operation

The length and character of the diastolic murmur are also unreliable guides, for several patients with tight stenosis had short quiet murmurs, and many patients with long loud ones have excellent exercise tolerance many years after mitral valvotomy The signs of mitral incompetence (whose importance has already been referred to) must be considered only in combination with the record of the findings at the end of the first operation

BRONCHITIS

Many patients with mitral-valve disease also have bronchitis, and some of the symptoms of raised left atrial pressure may simulate this condition Bronchitis may be responsible for the failure of a valvotomy, but, if there is any doubt about the part played by this condition, pulmonary function tests should be done Capel and Smart (1958) have shown by spirometery that cases in which the bronchitis is the more important factor can be fairly clearly distinguished from those in which the cardiac condition is the major cause of the disability If the fast expiratory ratio (F E R) is above 65%,

$$\frac{\text{1 sec forced expiratory volume}}{\text{fast vital capacity}} \times 100$$

the heart is almost certainly the organ most seriously affected, but as this figure decreases, obstructive airway disease is more and more likely to be responsible for the dyspnœa, and a second operation is less and less likely to achieve a good result

RADIOLOGY

Radiographs were found to be of little diagnostic value in cases of restenosis In many there was little significant change either in the vascular shadows or in the cardiothoracic ratio, despite the return of considerable effort intolerance The one common feature was the return or the appearance of septal lines As Grainger and Hearn (1955) have shown that these radiological appearances are due to raised left atrial pressure they are of great diagnostic importance, particularly where no incompetence is present

OTHER INVESTIGATIONS

Cardiac catheterisation and left atrial puncture were used in a few cases in this series, and were sometimes helpful, but in the majority clinical methods were sufficient to establish the diagnosis

Second Operation

INDICATIONS

By and large, when restenosis has been diagnosed, the indications for a second operation are the same as those for the first one Unless there is some contraindication, when a patient's disability returns to the level at which it was before the first operation, reexploration should be undertaken

The results of the operations in this series show that, although the mortality is a little higher than that of the primary operations, good results can be achieved by a second attack on the valve This is particularly true when the first one was inadequate What is perhaps more important is that Ross (1959) has shown that the prognosis in those patients whose first valvotomy has been a failure is surprisingly bad Among those who died from his series at the Middlesex Hospital, the majority did so within six months of the return of their symptoms to the preoperative level This being so, once the decision to do a second operation has been taken, the sooner it is done the better

TECHNIQUE AND FINDINGS

In all cases the approach was through the left atrium A right-sided approach has been recommended for operations for restenosis (Bailey et al 1956), because of the difficulties of dissecting the previous operative field, but this has the important disadvantage that it precludes the use of the transventricular dilator which is very often necessary if an adequate split is to be achieved The dissection, although occasionally tedious, never caused serious difficulties

In almost all the patients the atrial chamber was reached through an incision in the atrial wall the appendage had been amputated at the first operation On several occasions this route had been used already, but the scarring interfered very little with the placing of the purse-string suture on the second occasion One ring was found to be quite sufficient, but one or two reinforcing sutures were sometimes required to close the atrial wall

The valve was explored in the usual way In 22 calcification was present, and both Ross (1959) and Bailey and Goldberg (1957) have referred to the high incidence of calcification in patients requiring a second operation This is probably a significant finding only in so far as heavy calcification makes valvotomy by the classical method difficult, and its presence was responsible for the inadequacy of the first operation

In 43 patients it was felt certain that the valve orifice was smaller than it had been at the end of the first operation In these there was a considerable difference which could not be accounted for by errors of observation In 3 others it was thought that little alteration had occurred and that the patients had been operated on prematurely, of the remaining 4, 3 had had very inadequate operations on the first occasion and had improved very little, and 1, who died later, had severe mitral incompetence

Mitral incompetence was present in 21 cases, in 2 it was severe, but the correlation between the severity of the regurgitation recorded at the end of the first operation and that found on the second occasion was close, not only in my cases but also in those treated by other surgeons who had noted this important detail

After exploration of the valve, finger fracture of the commissures was attempted, but unless this was easily achieved (as it was in 4 of the cases of " true " restenosis) the transventricular approach was used This procedure almost always gave satisfactory results even when the valve was heavily calcified The dilatation was done gradually with the blades at right-angles to the direction of the commissures Often two dilators of different sizes had to be used They are so designed that their greatest force is exerted at the end of their range rather than at the beginning, for this reason it was sometimes impossible to start the split with the large dilator, and a small pulmonary or aortic dilator had to be used

Despite careful and gradual dilatation, incompetence was either created or worsened in 20 of the 42 cases in which the dilator was used, in 7 this incompetence was severe Despite the high incidence of incompetence, the transventricular method is at present thought to be that of choice In almost all cases it was possible to achieve a complete commissurotomy, and, as the results show, the incompetence did not prove as serious a complication as might have been expected

Carotid compression was applied during the manipulations, but cerebral emboli occurred in 3 cases (6%) this incidence was higher than that after first operations (Belcher 1956) when it was 2 5% This difference may be due to the high incidence of calcification, with the attendant risk of emboli due to small pieces of calcium broken off the valve edges during the commissurotomy In only 1 patient was the embolus lethal, in the other 2 the effects were transient

RESULTS

Of the 50 patients, 46 have been followed up for more than six months, the longest follow-up period being three and a half years The operative mortality was 8%, compared with 5 5% for the primary valvotomies Of the 4 patients who died, 1 did so from a calcium embolism discovered on X-ray of the brain at necropsy, 2 died from left ventricular failure in the early postoperative period, and 1 died at operation

In the remaining 42 patients the results were as follows

Results	*No*
Excellent	8
Good	17
Fair	10
Poor	4
Late death	3

Thus, over half the patients have a satisfactory increase in exercise tolerance, and in 11 this has been maintained for more than two years Of those who have not done so well, 3 had organic tricuspid-valve disease, and 5 had mitral incompetence, although in only 1 was this thought to be severe In the remainder the cause of the unsatisfactory results are not clear all had adequate commissurotomies

These results are almost as satisfactory as those which might be expected in a similar group of patients after primary operations On this ground alone reexploration of the mitral valves is justifiable The poor expectation of life in patients with restenosis is added justification for a second operation

Conclusions

Probably the number of patients presenting with restenosis of the mitral valve will increase, particularly in the group where the original operation has been inadequate Any patient who has had an increase in exercise tolerance and has thereafter deteriorated must be regarded as a candidate for a second valvotomy A second operation should be undertaken if other causes of failure can be excluded The results of second operations using the transventricular approach justify this policy, and the results of expectant treatment have been shown to be surprisingly bad

Summary

50 operations on account of restenosis of the mitral valve are reviewed

There were 29 cases of "false" restenosis, 17 of "true" restenosis, and 4 in which the size of the orifice had changed little since the first operation

31 of the cases were derived from a personal series of 294 valvotomies followed up for between one and seven years—an incidence of 11%

In the diagnosis of restenosis a detailed report of the first operation is important

The transventricular method of valvotomy has proved advantageous

The operative mortality was only a little higher than that associated with first operations, and the improvement in exercise tolerance was almost as good

GLOUCESTERSHIRE ROYAL HOSPITAL, GLOUCESTER

ALTHOUGH various forms of stress are known to increase blood fibrinolytic activity, only alimentary lipæmia (Grieg 1956) and pregnancy (Biezenski and Moore 1958, Gillman et al 1959) until now have been shown to diminish it Recently we have found that beer may induce profound reduction of fibrinolytic activity in the blood of healthy people During daily observations on a few people an unusual prolongation of blood-clot lysis-time occurred twice, and inquiry revealed a possible connection with the drinking of a glass of beer some three hours before the test This led us to investigate the effect of beer and other alcoholic drinks on blood fibrinolytic activity

Material and Methods

The subjects were healthy people aged 24–45

The method, already described (Fearnley et al 1957), in brief consists in measuring the time required for complete lysis at 37°C of clots made with thrombin of blood diluted 1 10 in phosphate buffer (pH 7 4) A low-temperature technique is essential During the earlier part of the work clot-lysis was judged visually, but following the kind communication by Dr H Lackner of a method of photographic recording (subsequently published by Lackner and Goosen [1959]), an apparatus consisting of a 'Perspex' constant-temperature bath, timing intervalometer, and camera was made for us by Messrs

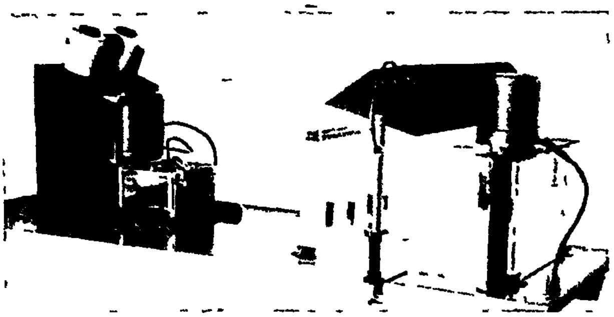

Fig 1—Apparatus for estimating lysis-time photographically

Shackman, of Chesham (fig 1) Photographs were taken at half-hourly intervals on 35 mm film The film negative is projected, or viewed with a hand lens, to obtain the lysis-times

The Study

Initial Experiments

Two-day experiments were conducted on 2 people (a man and a woman) to test several alcoholic drinks On the first or control day, no alcohol was taken and blood fibrinolytic activity was measured at 5 P M On the second or test day, an alcoholic drink was taken at 2 P M and blood fibrinolytic activity was measured as before at 5 P M Table I shows the results obtained with draught beer, cider, white wine, whisky, gin, and absolute alcohol The lysis-times of both subjects were greatly prolonged on the days on which beer (1 pint and 2 pints), cider, and white wine were taken, but were not significantly altered after gin, whisky, or absolute alcohol were taken The prolongation after ingestion of drinks in the former group was of the order of 300%

TABLE I—VENOUS CLOT LYSIS-TIMES IN A MAN AND A WOMAN ON CONTROL DAYS (NO ALCOHOL) AND ON TEST DAYS (3 HOURS AFTER INGESTION OF DRINKS LISTED)

Drink	Lysis-time (hr)			
	Man		Woman	
	Control	Test	Control	Test
Draught beer, 2 pt	4¾	17¼	5½	20
„ „ 1 pt.	4½	13¼	5	15
Cider, 1 pt.	5	24	7½	19½
White wine, 10 oz	5	14	5½	16
Gin, 2 oz.	5¼	6	5½	6½
Whisky, 2 oz	6½	5½	7	6
Absolute alcohol, 2 oz	5½	5½	4½	5

Experiments were then conducted on both subjects to determine the time and duration of the effect of 1 pint of beer Blood was obtained at 2 P M and the beer was drunk in 15 minutes, after which blood specimens were obtained 2, 4, and 6 hours after the first specimen Fig 2 shows that reduction of fibrinolytic activity was greatest at 2 hours, and that in the man the lysis-time had returned to near-resting level at 4 hours, but that in the woman it was still elevated at 4 hours falling to near the resting level at 6 hours

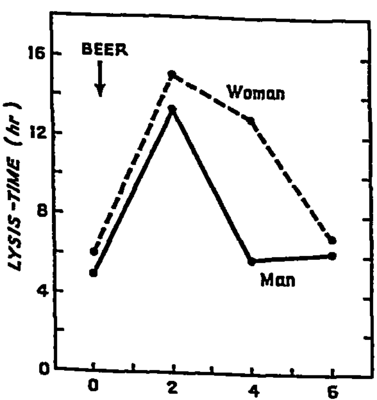

Fig 2—Fibrinolytic activity in relation to ingestion of 1 pint of beer

It thus seemed that consumption jects resulted in reduction of blood fibrinolytic activity which was maximal after 2 hours

Further Experiments

The effect of 1 pint of beer was tested on 14 healthy subjects (10 male and 4 female), blood being tested initially and 2 hours after the beer had been drunk For convenience bottled beer was used—two well-known brands of fairly high gravity Table II shows the results In 10 of the subjects (nos 1–10) prolongation of lysis-time was pronounced, in 3 subjects (nos 11–13) there was a small and insignificant prolongation, and in 1 subject (no 14) there was no effect whatever

TABLE II—CLOT-LYSIS TIMES OF 14 HEALTHY ADULTS (10 MALE AND 4 FEMALE) BEFORE AND 2 HOURS AFTER DRINKING 1 PINT OF BOTTLED BEER

Subject no	Sex	Lysis-times (hr)	
		Before	After
1	M	2	21
2	M	5	18½
3	M	4	16
4	M	5	16½
5	M	7	15
6	M	3½	12
7	F	7	22
8	F	4½	16
9	F	5¾	15
10	F	6	15½
11	M	8	10
12	M	4	6
13	M	4	6½
14	M	3½	3

Trial of Whisky

To 6 subjects whose lysis-time had been greatly prolonged by beer (nos 1, 2, 4, 5, 8, 9 of table II) 2 oz of whisky, which contained approximately the same amount of alcohol as a pint of beer, was given in 1 pint of water, and the lysis-times were measured initially and after 2 hours Table III shows that whisky in this dosage had no appreciable effect on the blood fibrinolytic activity of any of the subjects

TABLE III—CLOT-LYSIS TIMES OF SUBJECTS 1, 2, 4, 5, 8, 9 OF TABLE II BEFORE AND 2 HOURS AFTER DRINKING WHISKY 2 OZ IN 1 PINT OF WATER

Subject	Lysis-times (hr)	
	Before	After
1	5	4
2	6	5½
4	6	7
5	10	9
8	4	6
9	7	8

Trial of Absolute Alcohol

Absolute alcohol in water was given to 3 subjects in a dose of 1 oz and on another occasion 2 oz , and their blood fibrinolytic activity was measured initially and hourly for 3 hours In 1 subject (male) there was moderate prolongation of lysis-time of doubtful significance at 3 hours on the larger dose In another subject (male) there was no significant change In the 3rd subject (female), who was unaccustomed to alcohol, the larger dose produced intoxication and significant quickening of lysis-time from 6½ to 1¼ hours at the 2-hour bleeding, after which the experiment was terminated Owing to its unpleasant nature and taste, no further experiments were conducted with absolute alcohol

Discussion

Most, although not all, of the people tested showed a distinct prolongation of lysis-time and hence a reduction of blood fibrinolytic activity after drinking a pint of beer The increases of lysis-time were much greater than we have observed in healthy people given very fatty meals, and it would seem that at any rate in some people beer will induce profound reduction of blood fibrinolytic activity The quantity of beer used was moderate and even small compared with the quantities consumed by some habitual beer drinkers Whisky in a dosage of approximately the same alcohol content as the beer had apparently no effect, the results obtained with absolute alcohol were inconclusive but did not suggest that ethyl alcohol itself was the cause of reduced fibrinolytic activity following beer White wine and cider in two experiments appeared to have an effect comparable to that of beer These results suggest that some substance produced during fermentation and absent from distilled liquors may reduce blood fibrinolytic activity

Most of the people tested were accustomed to alcoholic drink, and 4 of the subjects in table II were asked to participate because they were in the habit of drinking a few pints of beer on one or more nights of the week In only 1 of these 4 (no 12) was there no significant alteration of lysis-time It does not seem, therefore, that reduction of blood fibrinolytic activity by beer is likely to cease with habituation

Until blood fibrinolytic activity has been proved to be of functional importance—which as yet it has not—it would be premature to speculate about the possible significance of these findings, and they do not in our view justify any further restriction on sufferers from vascular disease Their importance, however, to people who are measuring blood fibrinolytic activity is obvious

Summary

Preliminary experiments on 2 people indicated that draught beer, cider, and white wine greatly lowered blood fibrinolytic activity, whereas whisky, gin, and absolute alcohol did not

In 10 out of 14 people the ingestion of 1 pint of bottled beer was followed by pronounced lowering of blood fibrinolytic activity 2 hours later, in the remainder no significant change occurred

In 6 of the subjects who showed a response to beer, whisky in a dose of 2 oz had no significant effect on blood fibrinolytic activity

Absolute alcohol in 3 subjects yielded inconclusive results, but the evidence suggests that some fermentation product other than ethyl alcohol was responsible for the change in blood fibrinolytic activity which followed the drinking of beer

We wish to thank Messrs G D Searle & Co, Ltd, for their generous grant which defrayed the cost of the apparatus, Dr G R Venning, their medical director in England, for his great help and interest, Dr Edgar Davey for kindly giving us laboratory facilities, and our volunteers, who prefer to be unnamed

LIPÆMIA AND FIBRINOLYTIC POTENTIALITY *

C Hougie
M B Lond
ASSISTANT PROFESSOR

Florence Ayers
B S Roanoke College
RESEARCH ASSISTANT

From the Department of Clinical Pathology, University of Virginia, Charlottesville

Macfarlane (1937) was the first to demonstrate spontaneous fibrinolysis in the blood of patients after surgical operation With Biggs and Pilling he later found fibrinolytic activity in the blood of healthy volunteers after exercise or the injection of adrenaline (Biggs, Macfarlane, and Pilling 1947) In the technique used by these workers, the test plasma was diluted with a buffer and clotted by addition of thrombin, the rate of disappearance of the fibrin clots was then determined Fearnley, Revell, and Tweed in 1952 showed that if the plasma was kept chilled until the test was set up, fibrinolysis of varying degree could be demonstrated in healthy people even at rest

The rate at which the clot dissolves or lyses depends not only on physical factors, such as ionic strength and hydrogen-ion concentration, but also on the balance of inhibitors and activators in the diluted plasma For example, a decrease in an inhibitor without any change in the concentration of activators would enhance lysis Celander and Guest (1958) therefore proposed that the activity measured by such a dilution system be called the *fibrinolytic potentiality* of plasma This term emphasises that the test system does not measure merely plasmin (syn, fibrinolysin) which is believed to be the enzyme directly responsible for the breakdown of fibrin

Greig (1956) and Greig and Runde (1957) found that the lipæmia following a fatty meal significantly inhibited fibrinolytic activity Greig and Runde also found that the fibrinolytic activity of blood tends to be lower in people with a high serum-cholesterol level than in those with a lower level

There is evidence that platelets inhibit the action of plasmin (Johnson and Schneider 1953, Hume 1958), and they might therefore be expected to inhibit fibrinolytic potentiality But, so far as we know, this possibility has not been examined As cephalin can replace platelets in several coagulation test systems we thought that cephalin and platelets might have similar actions on fibrinolytic potentiality

The present work includes an attempt to answer these questions

Material and Methods

After trials of the method of Greig (1956), the method of Fearnley and Lackner (1955), a later modification of this method by Fearnley et al (1957) and several of our own modifications, all these were abandoned in favour of the method published in outline by Celander and Guest (1958), which was chosen as giving the greatest precision and the most reproducible results Our modifications and unpublished details of this method (Guest 1958) are

3 5 ml blood, collected into glass vacuum tubes, were mixed immediately with 1 0 ml of 3 8% trisodium citrate and 0 5 ml of 0 089 *M* KH_2PO_4 in a graduated siliconed centrifuge tube This blood was centrifuged (see below for details) and 0 3 ml portions of plasma were added to a number of tubes, each containing 5 0 ml phosphate buffer (pH 6 4), 0 2 ml thrombin (50 units per ml) and

---

*This investigation was supported by Grant H-3536 from the National Heart Institute, National Institutes of Health, Public Health Service, U S A a glass rod After the contents had been vigorously mixed, these tubes were kept in an ice-bath for thirty minutes The clots which formed were then immediately removed from the tubes by slowly turning the glass rods until all particles of the clots firmly adhered to their surface They were then " washed " by dipping them into another container holding more of this same buffer (pH 6 4) All reagents, material, and equipment, including blood, were kept ice-cold from the beginning of the experiment until after this clotting period

Initial estimation of fibrinogen was made from at least two clots, each dissolved in 1 ml *N* NaOH immediately after the thirty-minute period of clot formation Percentage lysis was determined from four clots, two of which had been left to lyse for exactly thirty minutes and the other two for sixty minutes, each in 5 ml phosphate buffer (pH 7 7), and then dissolved in NaOH. For the colorimetric procedure Lowry's modification of the Folin-Ciocalteau method was used

The standard deviation (S D) of our technique was calculated from a series of 20 duplicate results by a method described by Youden (1951) and was ±4 8% in terms of percentage lysis in one hour

TABLE I—COMPARISON OF FIBRINOLYTIC POTENTIALITY OF PLATELET-POOR AND PLATELET-RICH PLASMA

To determine the effect of platelets on the test system, the patient's blood (which was kept chilled) was placed in two identical 'Lusteroid' containers One of these was centrifuged for seven minutes at 1500 r p m (approximately 500 *g*) The other was spun at 15,000 r p m (approximately 15,000 *g*) for five minutes so as to sediment the platelets This latter specimen is referred to as platelet-poor plasma and the former as platelet-rich plasma

Washed platelets in suspension were prepared by the method of Biggs and Douglas (1953) They were used in a test within four hours of the time the blood for their preparation was drawn.

Control tubes run in each experiment contained an amount of 0 85% saline equal in volume to the material being tested (i.e , cephalin or washed platelets)

Results

Comparison of fibrinolytic potentiality of platelet-rich and platelet-poor plasma —Platelet-rich and platelet-poor plasma was obtained from each of 10 normal subjects and the lysis-rates were compared Table I shows that after one hour there was more lysis in the platelet-poor plasma than in the platelet-rich plasma The difference is significant at the 1% level

TABLE II—EFFECT OF ADDITION OF WASHED PLATELETS TO PLATELET-POOR PLASMA

9	63	64

Effect of addition of washed platelets to platelet-poor plasma —Table II shows that the twice-washed platelets inhibited fibrinolytic potentiality, but the level of significance was lower (5% level) than in the previous experiment

Effect of addition of cephalin to platelet-poor plasma —Cephalin prepared by the method of Bell and Alton (1954) and added to platelet-poor plasma was found (table III) to have no statistically significant effect on lysis in our test system

Effect of fatty and non-fatty meal on fibrinolytic potentiality of plasma —This experiment was carried out on 9 healthy males The fatty breakfast consisted of bacon, eggs, toast, a very large serving of butter, and at least one glass of cream, while the regular breakfast consisted of coffee-with-milk, fruit juice, and a dry bread roll The meals were taken between 7 30 and 8 0 A M and the blood was drawn three and a half to four hours later Care was taken to ensure that after the fatty and regular breakfasts the subject went through the same daily routine

The results (table IV) show no statistically significant difference in lysis after the fatty and the non-fatty meals, using either the half-hour or one-hour determinations

TABLE IV—LYSIS AFTER FATTY AND NON-FATTY MEALS

Experiment	% lysis after half an hour		% lysis after one hour	
	Regular meal	Fatty meal	Regular meal	Fatty meal
1	32 39	33 33	33 91	40 00

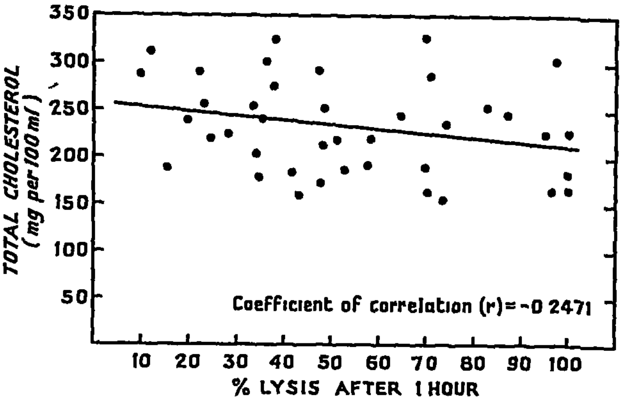
9	38 32	29 94	97 29	100·00

Relation of serum-cholesterol level on fibrinolytic potentiality of plasma —The subjects in this experiment were 40 normal people (28 males and 12 females) ranging in age from 15 to 60 Blood was drawn from 25 of them between 9 00 and 11 00 A M (in most cases at about 10 00) and from the remaining 15 patients between 1 30 and 2 30 P M (usually at 2 00) Although there is a normal diurnal fluctuation in lysis-rate (Fearnley et al 1957, Buckell and Elliott 1959a), there is also significant fluctuation from day to day even though blood is drawn at the same time of day and the person has taken the same food and done the same work Because of the large number of cases studied, we felt that variations of the type mentioned would be relatively unimportant The percentage lysis was determined after both thirty and sixty minutes There was no significant correlation between cholesterol level and fibrinolytic potentiality, either after sixty minutes' (see figure) or thirty minutes' lysis



Correlation of total cholesterol and percentage lysis with line of regression for all plotted points

Coefficient of correlation is —0 2471 To be significant even at the 0 05 level, this figure would have to be numerically greater than 0 304

Discussion

Our finding that a fatty breakfast did not significantly inhibit fibrinolytic potentiality is in striking contrast to Greig's finding of inhibition in all his 25 subjects Buckell and Elliott (1959a and b), using a method similar to Greig's, claimed to have confirmed his finding of significant inhibition of lysis following a fatty meal—at least in subjects aged 20–24 This conclusion, however, is not supported by inspection of their actual data (see table I, Buckell and Elliott 1959b), for the rate of lysis was decreased in only 8 of their 20 cases when determined after six hours and in 5 out of 20 when determined after twenty-four hours Nitzberg et al (1959) using the dilution method of Fearnley et al (1957), studied three groups of subjects 9 patients with idiopathic hyperlipæmia, 10 patients with primary hypercholesterolæmia, and 10 normal people In all but 3 of these 29 they found actual enhancement of fibrinolytic potentiality but they regard these results as inconclusive because of the limitations of the method We, too, have used this method, but abandoned it because we could not obtain precise or reproducible results Billimoria et al (1959) demonstrated a significant inhibition of lysis two hours after a fatty meal but found no significant inhibition of lysis four hours after a fatty meal, this latter finding is in accord with our results

As emphasised earlier, dilution methods which measure fibrinolytic potentiality do not necessarily measure plasmin, so our data do not exclude the possibility that fats inhibit plasmin It is interesting to note, however, that Buckell and Elliott (1959b), using a euglobulin lysis-time method, could find no significant difference in lysis-times after fatty and non-fatty meals This is a more specific method of measuring plasmin, since most inhibitors are removed during the euglobulin precipitation However, Mandel (1959), using a method which employs streptokinase activation and a visual endpoint has found delay of lysis in plasma after addition of fat, both in vitro and vivo He found that 'Lipomul' (peanut oil with dextrose) caused marked inhibition, whereas cream caused only moderate inhibition, and 'Arcofac' (containing linoleic acid) caused none Nitzberg et al also used a method involving streptokinase activation, and their results were similar to those of Mandel With this method (in contrast to their results with the dilution method) the majority of subjects showed some prolongation of lysis-times after a fatty meal

We were unable to confirm Greig and Runde's finding of a significant inverse correlation between level of cholesterol and fibrinolytic potentiality We have recently determined the fibrinolytic potentiality of a patient with familial hypercholesterolæmia (total serum-cholesterol 824 mg per 100 ml) Even though blood was drawn at 11 00 A M , when lysis-rate should be slower than in the early afternoon, the patient's fibrinolytic potentiality exceeded that of 23 of our series of 40 people whose blood was drawn either at this time or early in the afternoon This result indicates that the increased tendency to coronary disease in this condition may not necessarily be associated with diminished fibrinolytic potentiality

Summary

When a dilution test system is used, fibrinolytic activity is inhibited in platelet-rich plasma, as compared to platelet-poor plasma Cephalin appears to have no effect on fibrinolytic activity

We were unable to confirm the finding of others that *lipæmia inhibits fibrinolytic potentiality* Our results indicate that ingestion of butter, cream, and eggs has no significant effect on fibrinolytic potentiality determined between three and a half and four hours after the meal There was no significant correlation between fibrinolytic potentiality and the level of total cholesterol in the serum

We wish to thank Dr Richard Shaw of the department of preventive medicine, University of Virginia, for help with the statistics

TREATMENT OF WILSON'S DISEASE WITH PENICILLAMINE

J M WALSHE*
M A , M B Cantab , M R C P
ASSISTANT DIRECTOR OF RESEARCH, DEPARTMENT OF EXPERIMENTAL MEDICINE, UNIVERSITY OF CAMBRIDGE

PATIENTS with Wilson's disease are in positive copper balance (Cartwright et al 1954, Zimdahl et al 1954), and, as a result, copper accumulates in the tissues, principally the brain, liver, and kidneys, and is excreted in excess in the urine Deposition of copper in these organs is associated with degenerative changes, in the brain affecting most often the basal ganglia and leading to the tremor-rigidity syndrome, in the liver leading to cirrhosis, and in the kidneys leading to abnormalities of renal tubular function which in turn gives rise to glycosuria, amino-aciduria, phosphaturia, and uricosuria of the "low threshold" type. Deposition of copper in Descemet's membrane of the cornea is responsible for the development of the characteristic greenish-brown Kayser-Fleischer rings.

---

* The following collaborated in the preparation of this report Dr E Bental (Jerusalem), Dr J E Boulding (Essondale, British Columbia), Dr J Carson (Sheffield), Dr H G Garland (Leeds), Prof D V Hubble (Birmingham), Dr J Lange (Bonn), Prof W S Peart (London), Dr C T Potter (London), Dr J Richmond (Edinburgh), Dr R F Robertson (Edinburgh), Dr J S Robson (Edinburgh), Prof Sheila Sherlock (London), Dr J A Simpson (Edinburgh), Dr J K Slater (Edinburgh), Dr W Stokes (Aylesbury), Dr C G Warnock (Belfast), and Dr C B M Warren (Chelmsford)

Up to 1948 Wilson's disease was considered to be without treatment. In that year, however, Cumings pointed out that dimercaprol (BAL), by removing copper from the tissues, should be of benefit to patients with this condition. Subsequently there have been many reports on the therapeutic efficacy of dimercaprol, and most workers have agreed that it has a real, if limited, use in the management of Wilson's disease (Cumings 1948, Denny-Brown and Porter 1951, Bearn 1956), although in some series little benefit has been observed (Bickel et al 1957). One difficulty in understanding the response to dimercaprol has been the very poor correlation between the clinical and biochemical results leading some workers to wonder whether removal of copper from the tissues was as important as had been originally supposed (Bearn 1957, Uzman 1958, Walshe 1959). The introduction and trial of other therapeutic agents clearly testifies that dimercaprol is not the final answer to the treatment of Wilson's disease. Of these newer compounds penicillamine (ββ dimethyl cysteine) is the latest, and this is, in the majority of cases, the most powerful "decoppering" agent (Walshe 1956, Bearn 1957).

Hitherto no large series of patients treated with penicillamine has been published, so its clinical usefulness cannot yet be assessed. We have collected data on 22 cases treated with this compound, recorded its cupruretic action, its therapeutic effect, and, where possible, compared these with the corresponding actions of dimercaprol.

This report is not the result of a planned therapeutic trial. The results have been collected post hoc and are, therefore, lacking in certain details.

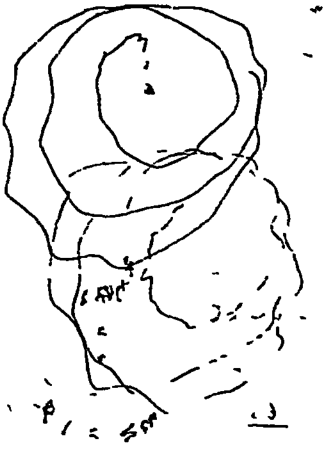

Fig 1—Case 19 spiral and attempted signature before treatment with penicillamine

Clinical Material and Methods

This report concerns 22 cases with Wilson's disease collected from sixteen hospitals (12 patients in England, 5 in Scotland, 2 in Canada, 1 in Northern Ireland, 1 in Germany, and 1 in Israel).

The average age at onset was 14·8 years, the youngest presented at the age of 8 years with hepatic enlargement and the oldest at 32 years with tremor (a patient who presented with cirrhosis at the age of 11 years had had an attack of "jaundice" at the age of 3 years) (table I).

The dosage of penicillamine (D-penicillamine hydrochloride, Distillers Company (Biochemicals) Ltd.) varied from 500 mg to 3 g daily, most patients receiving 900 mg or 1 g a day. The

TABLE I—CLINICAL DATA

Case no	Age (yr.)	Sex	Presenting symptom	Length of illness (mos.)	Serum-Cu (µg per 100 ml.)	Serum-oxidase activity	Urine Cu (µg per 24 hr.)	Remarks
1	23	F	Choreoathetosis	60		0·085	172	Advanced case with decorticate rigidity when first seen
2	12	F	Unsteady gait	42		Very low	540	Patient suddenly deteriorated and died in hepatic coma

* =9·4 mg. per 100 ml. as cæruloplasmin.

duration of treatment varied from four weeks to three years with an average of one year 16 of these patients received dimercaprol, either alone or in combination with penicillamine In most cases it was given in short courses of five days or a week, either every ten days or once a month Often a single weekly maintenance dose was also given The largest dose was 400 mg daily, the smallest 50 mg to a 12-year-old child

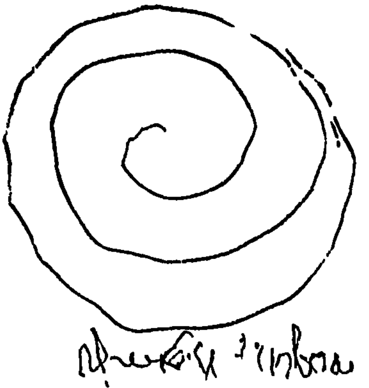

Fig 2—Case 19 improvement in spiral and signature after start of therapy

No attempt has been made to report on chemical methods as the results have been collected from so many laboratories Cæruloplasmin was, in most cases, estimated as units of oxidase activity, according to Ravin (1956), though in other cases the content was recorded as " low " or " very low " (presumably as Ravin units)

No one physician saw all the patients, and in any case assessment of clinical improvement is apt to be subjective, but, in our experience, it is usually obvious when benefit follows treatment Benefit has been recorded only when a patient became able to undertake tasks which were previously impossible, such as feeding or dressing himself. One of the best measures of improvement is by keeping records of handwriting and ability to draw a spiral (figs 1–4), but unfortunately such records are available in only a few of our cases

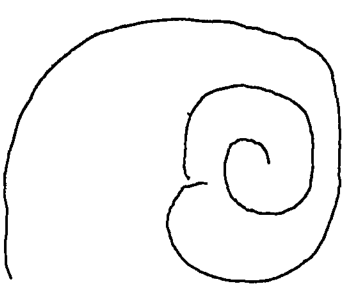

Fig 3—Case 19 further improvement in performance after 2 years' treatment

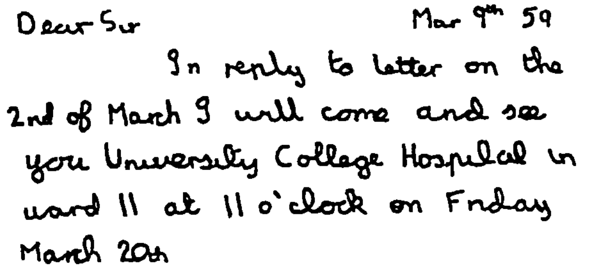
Results

Details of the results are shown in table II Of the 22 patients 2 (cases 5 and 6) were found to have the bio-

TABLE II—RESULTS OF TREATMENT

Case no	Dimercaprol			Penicillamine		
	Duration and dosage	Maximum urine Cu (µg per 24 hr)	Clinical response	Duration and dosage	Maximum urine Cu (µg per 24 hr)	Clinical response
1	Intermittent courses, 18 mos	Incontinent	Doubtful improvement, remained incontinent	1 month 1 g daily, later 3–4 g daily	1286	Delayed response but " spectacular effect "—much improved
2	10 days 50 mg daily	570	No response	10 weeks 1 g daily	1680	No response
3	Only given with penicillamine		No response	5 mos 1 5 g daily	3800	No response
4	14 days 100 mg daily		No response	6 mos 0 9–1 2 g daily	2330	No response—deteriorated Jacksonian epilepsy
5	7 yr courses each 3 mos	2835	Liver tests improved	3 yr 1 5 g bi-weekly	2200	No symptoms—remains well
6	14 days 80 mg daily	137	Given after penicillamine	2 mos 0 5 g daily	1340	No symptoms—remains well
7	Only with penicillamine	1450		4 mos 0 9 g daily	2550	Significant reduction of tremor
8	Monthly courses 3 mg per kg daily	2714	Temporary improvement only	2 yr 0 9 g daily	4524	From being bedridden has returned to school
9	Nil			15 mos 0 9 g daily	6250	From being helpless can now feed and dress herself and is nearing full term pregnancy*
10	7 day courses for several mos , 400 mg daily	1350	Deteriorated	15 mos 0 9 g daily	3600	Disappearance of all symptoms
11	Nil			9 mos 0 9 g daily	2000	From being helpless is now symptom free and successful wage-earner
12	3 days only, 200 mg daily	1000		22 mos 1 0 g daily	2500	Improved gait and speech Virtual loss of K-F rings
13	14 days 150 mg daily	900	No response	1 yr 0 9 g daily	3360	Chroeiform motions and limb motions much improved, slurred speech
14	Nil			15 mos 0 9 g daily		Very good—returned to full activities at school
15	Nil			13 mos 0 6 g daily	2380	Moderate improvement
16	Nil			12 mos 0 9 g daily	2270	All symptoms disappeared, normal school activities
17	2 courses, first total 5 6 g , second total 6 3 g	990	Improved	2 courses 2 mos and 4 mos 0 9 g daily	3428	Intention tremor improved Relapse 3 mos after treatment stopped
18	Courses of 1 week each	720	Initial improvement —not found with later courses of treatment	7 mos 0 9 g daily	400	Continued improvement—almost symptom-free Virtual disappearance K-F rings
19	3 courses 5 days 100 mg daily	600	Decreased rigidity	2 yr 0 9 g daily, 1 yr 0 45 g daily	3000	From being dysarthric and bedridden to full activities
20	8 weeks 70 mg daily	800	Febrile reaction Discontinued	2 yr 0 9 g daily	1200 (6 hr)	Much improved can now feed, shave, and dress himself
21	Nil			1 month 0 9 g daily	2100 (6 hr)	Improved writing, can now feed himself
22	5 days, 400 mg daily	1640	No response	8 mos 0 9 g daily	750	Much objective improvement in rigidity and tremor

* Subsequently delivered a normal full term child



Dear Sir Mar 9th 59
In reply to letter on the
2nd of March I will come and see
you University College Hospital in
ward 11 at 11 o'clock on Friday
March 20th

Fig 4—Case 19 clear and legible writing after 3 years on continuous penicillamine

chemical stigmata of the disease after the condition had been diagnosed in an elder sibling

Both these patients were found to have hepatomegaly, but, up to the time of writing, there was no evidence that the central nervous system was involved although Kayser-Fleischer rings were present Neither of these patients deteriorated on maintenance therapy 1 (case 5) showed a better cupruretic response to dimercaprol than to penicillamine, but as he had been under treatment for four years before the introduction of penicillamine the comparison may not be valid The other (case 6) had no increased excretion of copper after receiving dimercaprol, but this was given after two months on penicillamine

3 patients (cases 2–4) either did not improve or actually deteriorated under treatment, and 1 of these died from hepatic failure All 3 showed an excellent cupruretic response to penicillamine, though there is no evidence that they were in negative copper balance All were also treated with short courses of dimercaprol and similarly showed no improvement

TABLE III—SUMMARY OF TREATMENT RESULTS

Drug	Greatly improved	Limited improvement	No benefit	Prophylaxis	Toxicity	Not assessed
Penicillamine	6	11	3	2	1	0
Dimercaprol	1	2+1*	4	2	1	5

* Limited improvement, later deteriorated on treatment

17 cases remain in which the degree of benefit varied from " choreiform movements and control of limbs much improved but speech still slurred " to complete recovery so that, after being bedridden and helpless, they returned to full activity and have become symptom-free In 11 cases there was a good, but limited, response (cases 1, 7, 9, 12, 13, 15, 17, 18, 20–22), but 4 of these have so far received less than a year's treatment with penicillamine, and 1 (case 21) has been under treatment for only one month at the time of writing but already appears to be responding well Finally, 6 patients who were severely incapacitated and bedridden at the start of treatment with penicillamine were able to return to a normal degree of activity (cases 8, 10, 11, 14, 16, 19), and those who had shown signs of mental instability also improved in this respect In 2 patients significant fading of the Kayser-Fleischer rings was observed during the period of penicillamine therapy Of the 16 patients treated with dimercaprol 2 (already mentioned) were in the presymptomatic stage of the disease (cases 5 and 6), but only 1 of these had a good cupruresis after receiving the drug Of the remaining 14 patients, 1 improved greatly and 3 to a limited extent, but all had a poor cupruresis (cases 1, 17–19) Later all received penicillamine and continued to improve, 1 (case 19) falling into the group of " excellent response " 1 patient had a severe febrile reaction to dimercaprol, which was discontinued, and another refused further treatment because of pain at the injection sites (cases 20 and 18) 1 patient (case 8) had a good response to his initial treatment with dimercaprol, but then deteriorated despite adequate maintenance therapy He later had an excellent response to penicillamine, and this applied also to case 10 who on dimercaprol had gone downhill steadily 2 patients (cases 3 and 7) received dimercaprol only in combination with penicillamine The remainder (cases 2, 4, 12, 13, 22) were all treated for less than a month with dimercaprol, and their failure to respond does not necessarily mean the drug would not have been effective if therapy had been prolonged, but only 1 of these (case 22) had a good cupruresis following administration of dimercaprol (table III)

There was one serious toxic reaction to the D isomer of penicillamine, case 4 developing an erythematous rash and jacksonian convulsions There was, however, no other evidence of any anti-pyridoxine activity (as reported by Kuchinskas and du Vigneaud [1957] for L-penicillamine) or of depletion of other trace metals 2 patients developed transitory rashes which did not necessitate discontinuance of therapy although 1 of these required the simultaneous administration of an anti-histamine drug to control the rash

Discussion

While these results leave little room for doubt that penicillamine is of value in the treatment of Wilson's disease, they still do not answer the question Is the removal of copper from the body the mode of action of chelating agents? The alternative suggestion has been put forward that they may operate by providing sulphydryl groups for intermediary metabolism (Walshe 1959, Hill and Walshe 1959) In most cases in the present series penicillamine proved more active than dimercaprol, both in mobilising copper and in promoting clinical improvement, but 3 cases, despite satisfactory cupruresis showed no improvement or actually deteriorated This lack of correlation between biochemical and clinical findings remains one of the big unsolved problems of this disease What is the essential difference between patients who respond and those who do not? How can one predict in advance into which group any given patient will fall? Certainly the clinical condition of the patient when first seen and the initial cupruresis give no evidence on which to base prognosis As it costs approximately £1 a day to treat a patient with penicillamine, it would clearly be advantageous to know in advance whether any benefit will accrue, but it is still cheaper to treat a patient at home with this drug than to allow him to become bedridden and require hospital care, so (apart from other considerations) expense should not limit the use of penicillamine

In this study no attempt has been made to determine the minimum dose or to establish whether this can later be reduced for maintenance therapy, but in 3 patients (cases 10, 11, and 17) minimum effective therapeutic doses were established as 0 6, 0 9, and 0 9 g daily respectively Similarly, no mention has been made of the use of potassium-sulphide and low-copper diets to limit absorption of metal from the gut, although both measures should be employed Finally, the rate at which a patient will respond to treatment has not been discussed With dimercaprol any improvement generally occurs early, though it is not always maintained and later the patient may deteriorate on maintenance therapy With penicillamine the response appears to be slower, but when it occurs it is often continuous over several years so that the patient will eventually return to normal or near-normal although a relative biochemical resistance to the drug may develop The mechanism of such resistance and the minimum maintenance dosage have yet to be determined It will certainly be of advantage if others who may be undertaking the treatment of patients with Wilson's disease would join in a further scheme to evaluate the efficacy of various treatment schedules The plan of campaign should be carefully drawn up in advance

Summary

A collected series of 22 cases of Wilson's disease treated with penicillamine has been studied 16 of these patients also received dimercaprol either alone or synchronously with penicillamine

Of the 22 patients 3 showed no response, 11 showed limited improvement, and 6 became symptom-free, the remaining 2 were given penicillamine prophylactically before clinical evidence of neurological involvement appeared

Of the 16 patients treated with dimercaprol, 1 improved notably and 3 to a limited extent but 1 showed only temporary improvement, 4 did not respond, 2 were in the presymptomatic stage of the disease, and 5 received inadequate amounts of dimercaprol to draw conclusions

1 patient treated with dimercaprol had a severe febrile reaction necessitating cessation of treatment 2 patients on penicillamine had mild transitory rashes which gave rise to no inconvenience, 1 patient developed jacksonian epilepsy on this treatment

I thank Dr Michael Ashby, Dr H G Morgan, Dr S Nevin, and Dr W C Smallwood for allowing me to study their patients, and Dr C N Brown, of the Distillers Company (Biochemical) Ltd , for generous gifts of D-penicillamine hydrochloride

" Fundamentally the society in which we live does not care sufficiently about the dangers to which its members will be exposed when they enter the surgical part of its hospitals to give us the means we require in order to employ to the fullest extent the knowledge we already have about the prevention of infection, and to search with all our power for the further knowledge we need In 1965 it will be one hundred years since Lister first pointed the way toward the eradication of infection from surgical hospitals Shall we, his successors, be able to celebrate this event with a clear, happy consciousness of having worked as hard as he did to make his dream come true?"—Prof G J FRAENKEL, *The Example of Joseph Lister*, an inaugural lecture, p 10 (Dunedin University of Otago Press 1959 *2s 6d*)

EFFECT OF CORTICOSTEROIDS AND GLUTEN-FREE DIET ON ABSORPTION OF IRON IN IDIOPATHIC STEATORRHŒA AND CŒLIAC DISEASE *

JOHN BADENOCH
D M Oxon , F R C P
CONSULTANT PHYSICIAN

SHEILA T CALLENDER
M D St And , M R C P
FIRST ASSISTANT, NUFFIELD DEPARTMENT OF CLINICAL MEDICINE
RADCLIFFE INFIRMARY, OXFORD

IN idiopathic steatorrhœa and cœliac disease iron is absorbed very poorly, even in the presence of gross iron deficiency, and conventional treatment with a high-protein, low-fat diet and vitamin and mineral supplements does not improve the absorption of iron (Badenoch and Callender 1954)

Recently, corticosteroids and the gluten-free diet have been introduced for the treatment of these conditions, and, in contrast to earlier forms of therapy, both have been shown to improve the absorption of fat and other substances (Taylor et al 1952, Anderson et al 1952) From the rise in hæmoglobin which sometimes occurs with either form of therapy it has been assumed that iron absorption is also improved, but no direct evidence for this has been reported

In this study we have measured the effect of treatment with corticosteroids and gluten-free diet on iron absorption in patients with idiopathic steatorrhœa and cœliac disease and in control subjects, using radioactive iron as a tracer

Material and Methods

Ten patients with idiopathic steatorrhœa or cœliac disease were investigated The majority had been receiving treatment with a high-protein, low-fat diet and vitamin and mineral supplements, including folic acid, vitamin B_{12}, and iron, for several years As a result few were anæmic, but most of the blood-films showed evidence of iron deficiency and six of the ten had a serum iron of less than 50 μg per 100 ml

The controls were twelve patients without anæmia or disease of the gastrointestinal tract

An oral dose of 5 mg of iron labelled with 4–5 μC of ^{59}Fe was given to each patient as a solution of ferrous sulphate to which 25 mg of ascorbic acid had been added to ensure that the iron remained in a reduced form The dose was given while the subjects were fasting, and they received nothing by mouth for a further two hours

Throughout we have used the maximum radioactivity appearing subsequently in the blood as a measure of the absorption of iron, although in a few instances the unabsorbed radioactive iron in the fæces has also been measured It is well recognised that in iron-deficient subjects the proportion of the oral dose of iron which appears in the red cells is a good index of the amount absorbed In non-anæmic subjects it may represent only some 70–100% of that actually absorbed, but as we had evidence that steroids, given under the conditions of these experiments, do not alter significantly the percentage of the iron utilised (unpublished observations), we felt that for comparative studies before and after treatment the blood-levels alone were sufficient The maximum radioactivity in the blood was usually reached 10–15 days after the oral dose Activity was measured in 10 ml samples of blood and compared with that of a standard prepared from the individual oral dose (Badenoch and Callender 1954)

With the exception of one subject, who had been taking cortisone in a dose of 20–100 mg daily for 12 months prior to the test, steroids were administered to both patients and controls, either in the form of prednisone 40 mg daily for 5–6

---

* Based on a paper given at the Seventh International Congress of Hæmatology, Rome, 1958

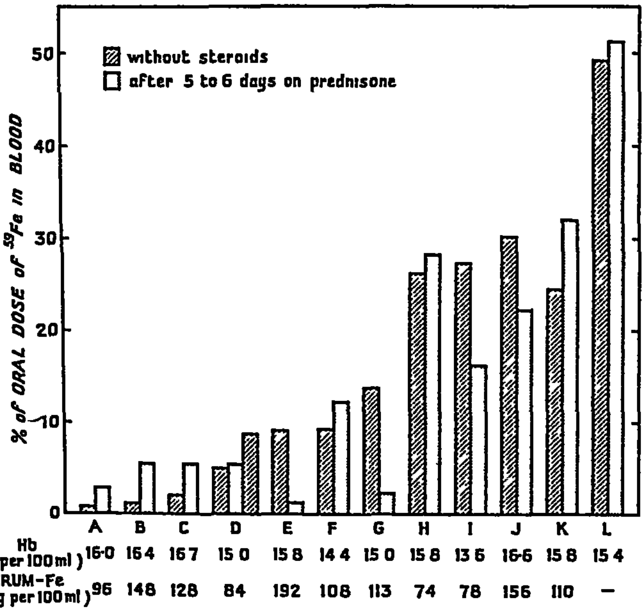

Fig 1—Effect of administration of steroids on absorption from 5 mg ^{59}Fe in control subjects

days before and 1–2 days after the dose of iron was given, or as corticotrophin 40 units intramuscularly daily for 3–4 days prior to the test

The effect of the gluten-free diet was assessed after it had been taken for periods ranging from 6 weeks to 1 year

Results

Effect of Steroids

In the twelve control subjects (fig 1) treated with prednisone 40 mg daily for 5–6 days there was no constant alteration in the amount of labelled iron which appeared in the red cells

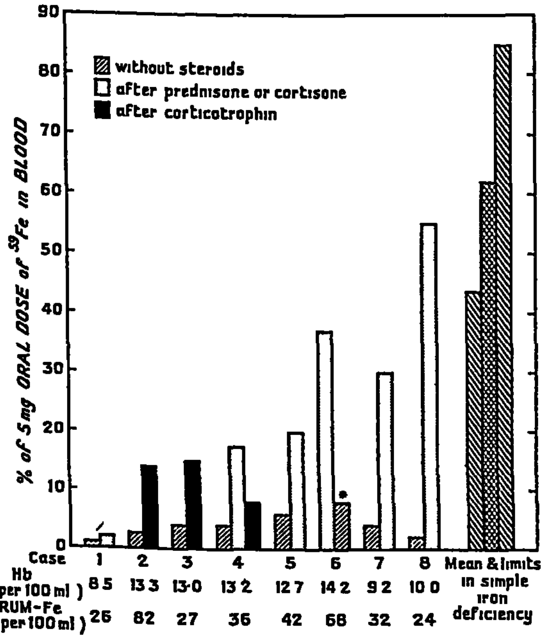
In uncomplicated iron deficiency some 45–83% (mean 61%) of a 5 mg oral dose of iron will appear in the red cells (Smith and Mallett 1957) In contrast, all the patients with steatorrhœa, including those with severe iron deficiency, showed greatly diminished absorption (less than 8%, mean 3 6%) (fig 2) Following treatment with prednisone or cortisone, the absorption of iron was increased to between 17 5 and 55% in every patient but one, with a mean of 27% The exception (case 1) was a very severe longstanding case in which, even after 3 weeks' treatment with prednisone, less than 2% of the dose of oral iron was absorbed Although the improvement in absorption following steroids was considerable in the others, in only three patients did it rise to levels comparable to those in simple iron deficiency

In case 6 the 37% absorption of iron was obtained after a year's treatment with cortisone for an accompanying rheumatoid arthritis The cortisone was discontinued and the test repeated after only 1 week without steroids The absorption had already dropped to 8%, although the patient's general condition remained excellent and she had no diarrhœa

Corticotrophin was administered to three patients and improvement in absorption was noted in all, but the difference was not as clear as that following the oral steroids

Effect of Gluten-free Diet

Following treatment with gluten-free diet, all the subjects noted improvement in their symptoms with a decrease in the diarrhœa, but the absorption of iron was not always increased, and only in case 3 was the improvement as dramatic as that following the steroids (fig 3) Case 3 was a young man with undoubted cœliac disease with hospital records going back to childhood, the improvement in absorption from 4 to 37% occurred after he had been only 6 weeks on the diet The three others (cases 7–9) who showed fair improvement had had symptoms in childhood with presumptive evidence of cœliac disease Cases 2, 4, and 10 had short histories with onset in adult life



* Off steroids 1 week before test

Fig 2—Effect of administration of steroids on absorption from 5 mg ^{59}Fe in patients with steatorrhœa

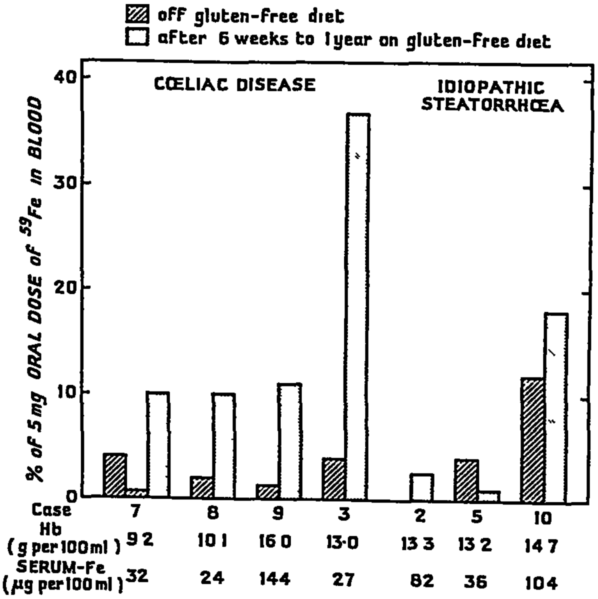


Fig 3—Effect of gluten-free diet on absorption from 5 mg ^{59}Fe in patients with steatorrhœa

Discussion

These studies provide evidence that both corticosteroids and a gluten-free diet may improve absorption of iron in patients with idiopathic steatorrhœa and cœliac disease

The way in which the improvement is brought about remains obscure Normally, in response to iron deficiency, an increased amount of iron is absorbed through the intestinal cell In the iron deficiency associated with idiopathic steatorrhœa and cœliac disease this does not occur. In these conditions the defect in iron metabolism appears to be solely in absorption, as parenterally administered iron is utilised normally This suggests that the improvement following steroids is due to a direct effect on the intestinal cell which can be brought about both by oral and parenteral treatment. It is unlikely to be due to a non-specific change in the permeability of the intestinal cell If it were, a similar effect should be evident in the control subjects, and we have been unable to demonstrate this

Cœliac disease is now believed to be due to a sensitivity to wheat gluten, although the exact mechanism is not understood It might be postulated, therefore, that the steroids exert a beneficial effect on iron absorption in cœliac disease and adult steatorrhœa by suppressing an abnormal antigen-antibody reaction

Summary

Studies with radioactive iron have shown that there is gross malabsorption of iron in patients with idiopathic steatorrhœa and cœliac disease

The absorption may be rapidly improved by the administration of cortisone, prednisone or corticotrophin, but decreases equally rapidly as soon as the drugs are stopped In control subjects steroids have no such constant effect

In cœliac disease a gluten-free diet improves the absorption of iron

RECENT CHANGE IN BLOOD-GROUP DISTRIBUTION OF ASTROCYTOMAS

PETER O YATES
M D Manc
SENIOR LECTURER IN NEUROPATHOLOGY

K M PEARCE
M B Manc, D C H
RESEARCH FELLOW, CHILDREN'S TUMOUR REGISTRY
UNIVERSITY OF MANCHESTER

IN an investigation into the ABO blood-group distribution in cerebral tumours Mayr et al (1956) found, in 385 gliomas of all types, no significant difference from the general population On the other hand, in a report on the first five years of the Manchester Children's Tumour Registry (1954–58) Steward (1959) noted an unusual preponderance of group A among children with gliomas In both these series the numbers for individual glioma types were small We report here our findings in 473 astrocytomas which indicate an apparent change in recent years in the blood-group patterns in this disease

The diagnosis was based on a recent reassessment of the pathological material by one of us (P O Y), tumours showing glioblastomatous features were excluded The ABO blood-grouping was taken from the case-records and was that performed at the time of admission to hospital for surgical treatment The cases were derived from neurosurgical centres in Manchester, which drain an area similar to that covered by the Manchester regional transfusion service For this reason the ABO figures from the latter have been used as controls (Stratton 1953) Because these figures, relating to blood-donors, are those for the adult population, and we wished to exclude any significant population changes in recent years, we collected a control series of blood-groups in children This consisted of 843 children under 15 years admitted to Manchester hospitals during the years 1947–58 for the treatment of burns Table I shows that the ABO distribution in this series is very close to that of the general adult donor population We have therefore used the latter throughout for statistical comparison For this purpose the figures of groups B and AB, being usually small, have been combined

TABLE II—DISTRIBUTION OF BLOOD-GROUPS IN ASTROCYTOMAS ACCORDING TO YEAR OF DIAGNOSIS

Year	A	B	AB	O	Total
1933–35	4			9	13
1936–40	26	4	1	28	59
1941–45	36	4	2	50	92
1946–50	42	11	5	34	92
1951–55	60	17	8	56	141
1956–58	43	5	3	25	76
Before 1946	66 (*40 2%*)	8 (*4 9%*)	3 (*1 8%*)	87 (*53%*)	164
After 1945	145 (*46 9%*)	33 (*10 7%*)	16 (*5 3%*)	115 (*37 2%*)	309

A superficial examination of the figures for astrocytomas as a whole (table I) does not reveal any great change from the controls ($\chi^2_{[2]}=6$, $P=0\ 05$) but there is some reduction in the percentage of group O and a corresponding increase of A The difference, though small, is unlikely to be fortuitous There does not appear to be the degree of preponderance of A suggested by the figures from the Manchester Children's Tumour Registry for the past five years

When, however, the cases are arranged according to the year in which diagnosis and blood-grouping was carried out (table II) a change of pattern appears after 1945 Those before that date show the expected distribution, those after show a very significant reduction of group O ($\chi^2=17$, $P=0\ 0002$) It might be argued that, if children with astrocytomas have always shown a reversal of the blood-group A/O ratio, then greater numbers of children in the second period would produce an apparent change in the pattern of astrocytomas as a whole In the cases under 20 years of age (table III) there is a highly significant change of pattern with an increase of A, B, and AB at the

TABLE I—INCIDENCE OF ASTROCYTOMAS ACCORDING TO BLOOD-GROUPS

expense of O. For the period after 1945 $\chi^2_{[2]}=25{\cdot}2$, $P<0{\cdot}00001$. At this point it is necessary to provide some indication that faults in blood-grouping technique in earlier years are not a contributory factor. For this purpose we give the figures for 322 meningiomas (table IV) which have shown a fairly constant normal blood-group distribution throughout the years.

The change observed in the under-20 age-group suggests that the phenomenon may be more closely linked with year of birth rather than year of diagnosis. Analysis according to year of birth (table V) shows that, whilst those born before 1931 have a fairly normal distribution of blood-groups, those born after 1930 show a considerable proportional reduction of group O ($\chi^2_{[2]}=20{\cdot}8$, $P<0{\cdot}00003$).

TABLE IV—BLOOD-GROUP DISTRIBUTION OF MENINGIOMAS ACCORDING TO YEAR OF DIAGNOSIS

Year	A	B	AB	O	Total

Before 1946	37 (*38·6%*)	11 (*11·5%*)	2 (*2·1%*)	46 (*48%*)	96
After 1945	94 (*41·6%*)	16 (*7·1%*)	7 (*3·1%*)	109 (*48·2%*)	226
Total	131 (*40·7%*)	27 (*8·4%*)	9 (*2·8%*)	155 (*48·1%*)	322

Discussion

The proportion of cases which have been examined for ABO blood-groups has varied from time to time according to factors such as surgical technique, fashions in surgical treatment, and changes of clinical staff. It seems unlikely that any alteration of the distribution of groups within a tumour type could result from such factors. A more likely source of error would be increasing skill and experience of laboratories in blood-grouping techniques, but a changing pattern from this cause should not discriminate between tumour types. The lack of change in the meningiomas suggests that faults in blood-grouping were never great enough to be statistically appreciable.

TABLE V—DISTRIBUTION OF BLOOD-GROUPS IN ASTROCYTOMAS ACCORDING TO YEAR OF BIRTH

Year	A	B	AB	O	Total
1871–90	7	2	0	11	20
1891–1900	25	4	3	41	73
1901–10	45	8	2	42	97
1911–20	32	7	3	28	70
1921–30	37	6	2	45	90
1931–40	28	6	4	18	56
1941–50	30	7	4	15	56
1951–55	7	1	1	2	11
Before 1931	146 (*41·7%*)	27 (*7·8%*)	10 (*2·9%*)	167 (*47·7%*)	350
After 1930	65 (*52·8%*)	14 (*11·4%*)	9 (*7·3%*)	35 (*28·4%*)	123

We cannot completely exclude the possibility of a change in blood-group pattern in this region due to migration, since we have been unable to obtain an adequate control series of children grouped before 1945, but the close agreement between our children with burns and the adult blood-donors (who were presumably children in the earlier period) would suggest that this is not significant. This is supported by the stability, through the years, of the ABO distribution of the meningiomas.

An increasing programme of immunisation in childhood, using antigens many of which may contain blood-group substances, will alter the antibody status of the serum of a considerable proportion of the population. But this is unlikely to have affected the red blood-cells, and our control series of children with burns shows in fact a normal blood-group pattern.

The astrocytomas are not a homogeneous group. They show various degrees of growth activity and of differentiation; they can also be divided into an adult type, almost confined to the cerebral hemispheres, and a juvenile type. The latter is known by many names, including cerebellar astrocytoma, optic-nerve glioma, piloid glioma, and spongioblastoma. The change in blood-group distribution occurs in both types, but since it is a feature of youth it is much more obvious in the juvenile astrocytoma. It would not be useful to present here figures for the various anatomical sites and pathological subtypes. Our impression is that the phenomenon we have described is present in all.

Until our results are confirmed or refuted from other centres it is not profitable to speculate about the underlying causes. We cannot yet be certain whether there is a rise in the incidence of astrocytomas in people of groups A, B, and AB or a fall in those of group O. Possibly some factor has appeared facilitating regression of astrocytomas in people of group O similar to the known regression in the clinically more obvious retinoblastomas.

In recent years many reports have pointed to an abnormal distribution of blood-groups in disease. We are not aware of any in which a change in the pattern has been reported. It seems, however, that if our observation that the change first appears in those born after 1930 is confirmed, then it will still be apparent only in diseases which are common in children and young adults.

Summary

An investigation of the ABO blood-group distribution in 473 astrocytomas shows a slight reduction in the proportion of group O when the cases are considered as a whole ($\chi^2_{[2]}=6$, $P=0{\cdot}05$).

The figures have been analysed according to the year of diagnosis. Whereas before 1946 the blood-groups were distributed normally, after 1945 there is a very significant reduction of group O ($\chi^2_{[2]}=17$, $P=0{\cdot}0002$). This is shown to be largely due to a change in the blood-group distribution in children and young adults with astrocytomas. This phenomenon is present in those born after 1930 ($\chi^2_{[2]}=20$, $P<0{\cdot}00003$), those born before that date showing a normal pattern.

We thank Mr B. D. Dawson, Mr A. N. Guthkelch, Mr R. T. Johnson, and Mr J. M. Potter, who allowed us to examine the case-notes of their patients, Dr H. B. Marsden for some of the pathological material, Miss R. Davidson and Mr J. C. Hughes for help in searching records, and the records officers, of the hospitals concerned for their cooperation.

DURING recent years the possible relationships between dietary fats and blood-lipids, particularly cholesterol, on the one hand and between blood-lipids and atherosclerosis on the other have aroused much interest. These problems are of great practical significance in Finland, where the consumption of fats is high (Roine et al. 1958), serum-cholesterol values unusually high, and the atherosclerotic diseases very common (Keys et al. 1958). It has been demonstrated beyond doubt that changes in dietary fats will alter the serum-cholesterol values, although there does not yet seem to be complete unanimity about the effects of different fatty acids and other components of natural fats and oils in this respect (Ahrens et al. 1957, Beveridge et al. 1958, Horlick and Craig 1957, Keys et al. 1957, Kinsell and Sinclair 1957). There is also considerable evidence in favour of the view that high blood-lipid values may be conducive to atherosclerosis, although this question can hardly be regarded as settled.

TABLE I—COMPOSITION OF DIETS IN THE HOSPITALS BEFORE AND AFTER THE DIETARY CHANGE (CONSUMPTION PER CAPUT PER DAY)

—	Hospital E		Hospital C	
	Before change (Aug. '58)	After change (Feb. '59)	Before change (Aug. '58)	After change (Feb. '59)
Energy (k cal.)	3018	2974	3058	2925
Protein (g.)	107	103	104	100
Fats				
Amount (g.)	114	106·5	120	115
% of total food energy	34·0	32·2	35·3	35·4
Fatty acids (g.)				
Saturated	59·4	42·6	60·6	60·3
Monoethenoids	40·0	38·1	42·5	39·0
Linoleic acid	7·6	16·8	8·8	8·0
Other polyenthenoids	1·5	4·4	2·2	2·1

There were no appreciable differences in carbohydrate, mineral, or vitamin content of the diets between the two hospitals.

The studies of which this is a preliminary account were started in the autumn of 1958 with the aim of ascertaining: (1) whether it was possible to devise dietary changes which would be acceptable in the long run, and at the same time would cause a substantial decrease in serum-cholesterol values, and (2) whether such a lowering of serum-cholesterol would have any effect on the development of atherosclerotic manifestations. While the first part of this work could obviously be carried out in a relatively short time, it was evident that the second part would require a rather long period of observation—at least a few years.

Method

For this work two mental hospitals in the vicinity of Helsinki were selected. In one of these (hospital E) the dietary changes described below were instituted, while the other (hospital C) was kept as the control hospital. Hospital E had 1100 beds, and hospital C had 640 beds.

Diets

The food consumption before the experiment was similar in the two hospitals. To the total food energy various constituents contributed as follows:

	Hospital E	*Hospital C*
Cereals (mainly wheat and rye)	29%	24%
Meat	10%	10%
Potatoes	10%	10%
Sugar	7%	12%
Milk	20%	18%
Butter	9%	9%
Margarine	4%	5%

Total daily consumption of fats was in hospital E 114 g. and in hospital C 120 g. This quantity comprised:

	Hospital E	*Hospital C*
Milk fat	57%	52%
Meat fat	19%	19%
Margarine fat	12%	14%
Vegetable oils	2%	4%

The diet in hospital E was changed in two respects. First, whole milk was replaced by a 3·5% emulsion of soybean oil in skim milk. The oil used was fortified with vitamins A and D so that the final product contained 70 I.U. of vitamin A and 10 I.U. of vitamin D per 100 ml. Secondly, butter and margarine were replaced by a special brand of margarine considerably more unsaturated than any of the brands marketed in Finland. Its iodine value was 78–80, and its content of chief unsaturated fatty acids was as follows: oleic 28%, linoleic 15·8%, and linolenic 4·9%. The main effect of these dietary changes was that the milk fat present in the original diet was almost totally replaced by vegetable oils, mainly soybean oil.

TABLE II—FOOD ENERGY DERIVED FROM TWO GROUPS OF FATTY ACIDS (% OF TOTAL ENERGY) BEFORE AND AFTER THE DIETARY CHANGE

—	*Hospital E*		*Hospital C*	
	Before change (Aug. '58)	After change (Feb. '59)	Before change (Aug. '58)	After change (Feb. '59)
Saturated fatty acids	17·7	12·9	17·9	18·6
Linoleic and other polyethenoid acids	2·7	6·4	3·2	3·1
Ratio saturated/polyethenoids	6·6/1	2·0/1	5·6/1	6·0/1

The composition of the diets in hospital E and hospital C before and after the dietary change is shown in table I. This table shows that the fatty-acid composition remained very nearly the same in hospital C. In hospital E, however, the dietary change resulted in a very definite change in the fatty-acid composition of the diet. The amount of saturated acids consumed decreased considerably, while consumption of linoleic and other polyethenoid acids increased. Table II shows the percentages of food energy derived from these two groups of fatty acids before and after the dietary change in both hospitals.

Serum-cholesterol Values

To follow the effects of dietary changes on blood-lipids a group of male patients 35–64 years of age was randomly selected in each hospital. The total serum-cholesterol of each subject was determined before and after the dietary change. A modification (Anderson and Keys 1956) of the method of Abell et al. (1952) was used.

Results

The results are shown in table III. In hospital E, in which the diet was changed as described above, the mean

TABLE III—SERUM-CHOLESTEROL VALUES BEFORE AND AFTER THE DIETARY CHANGE

—	Hospital E	Hospital C
No. of patients	117	53
Mean age (yr.)	49·8	48·3
Mean serum cholesterol (mg. per 100 ml.)		
Before dietary change (Aug. '58)	235·7	252·7
After dietary change (Feb. '59)	215·3	262·7
Cholesterol change (mg. per 100 ml.)	20·4	+9·6
S.E.	±3·2	±5·7
t	6·4	1·7
P	<0·001	0·1

TABLE IV—PREDICTED * AND OBSERVED MEAN SERUM-CHOLESTEROL VALUES (MG PER 100 ML.) AFTER THE DIETARY CHANGE

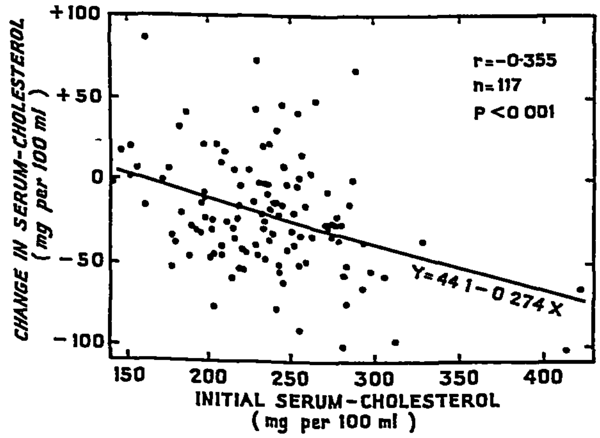
—	No of patients	Before change (G)	After change		
			Predicted * (G)	Observed	Difference
Hospital E					
All	117	235 7	215 8	215 3	+0 5
"Highs"	59	268 7	243 7	241 4	+2 3
'Lows'	58	202 1	187 3	188 7	−1·4
Hospital C	53	252 7	255 2	262 3	−7 1

* According to Keys et al (1959)

blood-cholesterol decreased appreciably—i e , from 236 mg to 215 mg per 100 ml serum In hospital C, in which the normal house diet was continued, there was, on the contrary, a slight increase in blood-cholesterol—i e , from 252 mg to 262 mg To assess the statistical significance of this change the difference in serum-cholesterol between the value before and that during the experiment was computed individually for each patient, and further the mean and standard error of this mean were calculated. The decrease in mean serum-cholesterol value observed in hospital E proved to be statistically highly significant, while the increase in hospital C was not significant by customary standards

There were large individual variations in the serum-cholesterol response to the dietary change, which was obviously influenced by several factors One of these is the height of the serum-cholesterol value before the dietary change (Keys et al 1959) The higher the initial serum-cholesterol the greater its decrease tends to be This is shown in the accompanying figure—a correlation diagram in which the change of serum-cholesterol is plotted against the initial serum-cholesterol value There is a definite negative correlation between these two factors The correlation coefficient is

$$r=-0\ 355$$



Correlation between the change in the serum-cholesterol value and the initial level.

a value which, though not particularly high, is nevertheless highly significant ($n=117$, $P<0\ 001$) The dependence of the serum-cholesterol change (Y) on the initial serum-cholesterol value (X) is defined by the regression equation

$$Y=44\ 1-0\ 274\ X$$

Keys et al (1959) have developed equations purporting to predict the changes in serum-cholesterol values which follow changes in fatty-acid composition of the diet We have applied such a prediction equation to our data. Since our groups of patients differ from the reference group of Keys et al both in initial serum-cholesterol value and in the composition of their diet, we had to use the more general type of equation

$$G_3=0\ 91\ (Z_2-G_2-Z_3)+1\ 91\ G_2Z_3/Z_2$$

In this equation G_2 and G_3 refer to mean serum-cholesterol values before and after the dietary change, respectively Z_2 and Z_3 are factors which are computed from the fatty-acid composition of diets as follows

$$Z_2=175+2\ 68\ S_2-1\ 23\ P_2 \text{ and}$$
$$Z_3=175+2\ 68\ S_3-1\ 23\ P_3,$$

where S_2 and S_3 refer to percentages of the total food energy contributed by glycerides of saturated fatty acids before and after the dietary change, respectively, and P_2 and P_3 refer to the corresponding percentages contributed by glycerides of polyethenoid fatty acids

The predicted and the observed serum-cholesterol values after dietary change appear in table IV In hospital E the prediction was carried out not only for the whole group as such but also for the group divided into two subgroups the "highs", having initial serum-cholesterol values above the mean of the whole group, and the "lows", having serum-cholesterol values below the mean There is excellent agreement between the prediction and the observation in the material from hospital E In hospital C, though there was no intentional change, the fatty-acid composition of the diet did not remain quite the same The prediction equation also indicated a change —namely, a slight increase—while the observed change was a somewhat greater increase In view of the relatively large variation of serum-cholesterol, in this case, too, the agreement between the prediction and the observation is good

Discussion

The dietaries in these hospitals are typical of Finnish dietaries in general in that they contain large quantities of whole milk and butter The work reported here shows that the replacement of whole milk by a soybean-oil emulsion in skim milk, and that of butter by a special type of margarine, results in a statistically highly significant, though not very large, decrease in the mean serum-cholesterol value The practical significance of this change is somewhat increased by the fact that the subjects with higher initial serum-cholesterol levels also tend to show greater decreases It is not yet clear whether this relatively modest lowering of serum-cholesterol will have any effect on the frequency of coronary-artery disease and other atherosclerotic manifestations, but we hope that the clinical and electrocardiographic investigations now in progress will soon shed light on this point Quite possibly we shall have to devise means to reduce serum-cholesterol further in order to influence the development of these pathological processes This could perhaps be accomplished by, for example, further increasing the degree of unsaturation of the component fats of the margarine

Summary

The ordinary house diet of a mental hospital was changed by replacing whole milk by an emulsion of soybean oil in skim milk and by replacing butter and margarine by a special brand of margarine considerably more unsaturated than the ordinary margarines marketed in Finland

These changes decreased the saturated-fatty-acid content of the diet and increased its content of linoleic and other polyethenoid acids

After this dietary change the mean serum-cholesterol

value of the 35–64-year-old male patients decreased from 236 mg. to 215 mg. per 100 ml. serum. This decrease was statistically highly significant.

We wish to express our gratitude to Mr. Heikki Kerkkonen, Parma Ltd., and to Dr. Matti Antila, of Raisio Factories, for the development of the special milk and margarine products used in this work.

EARLY SYMPTOMS OF PRE-ECLAMPTIC TOXÆMIA

KATHARINA DALTON
M.R.C.S.

GENERAL PRACTITIONER, EDMONTON; HONORARY CLINICAL ASSISTANT TO DEPARTMENT OF PSYCHOLOGICAL MEDICINE, UNIVERSITY COLLEGE HOSPITAL, LONDON, W.C.1

IN previous work on pre-eclamptic toxæmia certain warning symptoms were noted well in advance of any signs (Dalton 1954). This finding has since been corroborated in the course of trials of the prophylactic value of progesterone. Patients between the 16th and 28th weeks of pregnancy were asked "Do you feel as well now as before you became pregnant?"; and the subsequent history of the pregnancy has been found to differ in those who said "yes" and those who said "no".

At the antenatal clinic of the Obstetric Hospital, University College Hospital, London, between the years 1955 and 1958 the registrars put this question to 386 patients attending for routine examination at the 16th or 28th week (first series), and in 1958 I questioned 247 patients attending for examination at any time between the 16th and 28th weeks of pregnancy (second series). Patients who said that they felt less well than before their pregnancy were asked if this was due to nausea and vomiting, headaches, backaches, vertigo, fainting, paræsthesia, or lethargy. In the second series those with symptoms were also asked if they felt depressed, and in addition a note was made of those patients who felt better than usual.

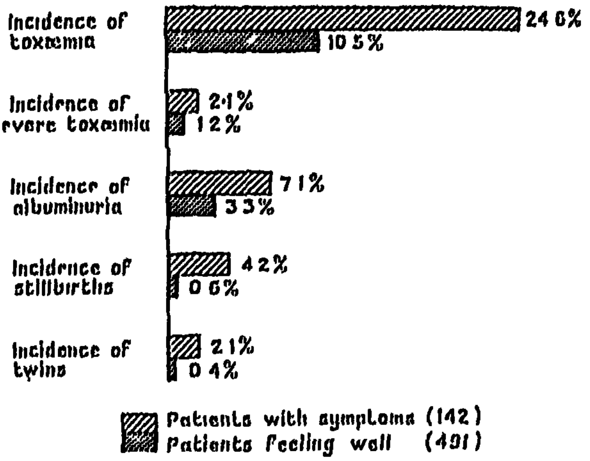
In this investigation pre-eclamptic toxæmia was diagnosed if a woman, previously free from hypertension and albuminuria, was found after the 28th week to have a blood-pressure of 140/90 mm. Hg or over, with œdema or with albumin in a catheter specimen.

Results

Of the 670 patients who were questioned 12 were excluded because antenatal care was not completed (abortion or cancelled booking) and 25 had a blood-pressure of at least 140/90 before the 28th week. Of the remaining 633, 491 (78%) said that they felt well and 142 (22%) had symptoms. The striking difference in the incidence of toxæmia in these two groups is shown in table I: of the women who had symptoms between the 16th and 28th week, one in every four developed toxæmia, compared with one in every ten who had felt well.

TABLE I—INCIDENCE OF TOXÆMIA

Patients	Series	Toxæmia	Normal	Total
With symptoms	1st 2nd	13 (25%) 22 (24%)	38 69	51 91
	Total	35 (25%)	107	142
Feeling well	1st 2nd	34 (10%) 18 (12%)	301 138	335 156
	Total	52 (11%)	439	491



Differences between patients with symptoms and those feeling well between the 16th and 28th weeks of pregnancy

The figure shows that the patients with symptoms during the middle trimester also had double the incidence of a more severe grade of toxæmia (with a blood-pressure of at least 140/90 mm. Hg, and both œdema and albuminuria), double the incidence of albuminuria, a higher stillbirth-rate, and more twin pregnancies. The incidence of œdema was not significantly different (33% in patients with symptoms compared with 37% in patients feeling well).

TABLE II—SYMPTOMS IN THE MIDDLE TRIMESTER

—		Toxæmia	Normal
Nausea and vomiting	(142 patients)	65%	71%
Headache	" "	35%	42%
Backache	" "	44%	51%
Lethargy	" "	88%	78%
Vertigo	" "	26%	20%
Fainting	" "	12%	9%
Paræsthesia	" "	46%	30%
Depression	(91 patients)	52%	50%

In the second series 33 patients (13%) said they had felt better than usual since becoming pregnant. Of these 3 (9%) developed toxæmia, and 1 (3%) developed albuminuria, there were no stillbirths or twins and 13 patients (39%) developed œdema. Thus there was little difference between the patients who felt well and those whose wellbeing had actually improved with pregnancy.

142 women complained of symptoms, and little difference is apparent in the symptoms of those who afterwards developed toxæmia and those who did not (table II).

An analysis of the number of symptoms suggests that these women did not lightly complain, for 94% had at least two unrelated symptoms, 71% had three, and 48% had at least four. At another London maternity hospital, I found that 72% of 136 patients had three or more unrelated symptoms and 51% admitted to four or more (Dalton 1957).

In the second series some patients were interviewed more than once. Of 74 patients with symptoms on only one occasion, 20% developed toxæmia, whereas among the 17 whose symptoms persisted from one interview until the next (a month later) 41% did so The series was also analysed as regards the duration of pregnancy at the time of the interview, but no difference was found in the incidence of toxæmia among patients with symptoms and among those feeling well at the 4th, 5th, or 6th month of pregnancy

Discussion

The presence of symptoms between the 16th and 28th weeks of pregnancy suggests that the factor responsible for pre-eclamptic toxæmia is already operating many weeks before the development of signs Further it suggests that in any patient who has symptoms—even if there are no signs and no excessive gain in weight—prophylactic treatment of toxæmia should begin during the middle trimester The similarity in type and distribution of symptoms among those patients afterwards developing toxæmia and in those whose pregnancies proceed normally suggests that the patients with continuing symptoms may have subclinical toxæmia

Summary

In a series of 633 patients one in every four women with symptoms between the 16th and 28th weeks of pregnancy subsequently developed toxæmia, compared with one in every ten women who were feeling well during these middle months Those with symptoms during the middle trimester also had a greater incidence of albuminuria, stillbirths, and twins It is suggested that patients with symptoms during pregnancy should be treated with a toxæmic prophylactic regime even in the absence of signs or excessive weight gain

It is a pleasure to express my thanks to Prof W C W Nixon for allowing me to carry out these trials in his hospital and to his registrars for their assistance, and to Prof D D Reid for his statistical assistance

J E Kerrich
PROFESSOR OF STATISTICS, UNIVERSITY OF THE WITWATERSRAND

From the Central Mining-Rand Mines Group, Johannesburg, South Africa

SEVERAL authors have reported favourably on the use of adrenal steroids combined with antituberculous drugs in the treatment of tuberculous pleural effusions (Sors and Trocme 1954, James 1956, Aspin and O'Hara 1958), but as far as we are aware no controlled therapeutic trial has so far been carried out Such a trial was designed to evaluate this method of treatment in African mine labourers employed in the goldmining industry of the Witwatersrand, among whom pleural effusions are relatively common

In selecting cases for the trial we were faced with the difficulty that some medical officers concerned with the care of African mine labourers doubt whether tuberculosis is the major cause of pleurisy with effusion in this population This view is based on the fact that it is unusual to isolate tubercle bacilli from the pleural fluid Because of the extremely high incidence of pneumonia among these patients, some doctors are of the opinion that a substantial number of cases are postpneumonic in origin Others consider that scurvy, which is not rare, may account for those effusions which are hæmorrhagic (approximately a third of the total) Nevertheless, we regard the majority of cases, including the hæmorrhagic ones, as tuberculous This is supported by the high incidence of tuberculosis in these labourers, by the thoracoscopic findings (Fleishman et al 1956), and by the follow-up study of Stott and Brass (1955) The diagnosis of tuberculous pleural effusion in the cases entering the trial was based, therefore, on evidence which, though presumptive, is generally regarded as sound This evidence has been reviewed by Roper and Waring (1955)

It is for these reasons that the trial included four different methods of treatment—namely, ascorbic acid, penicillin, standard antituberculous therapy, and standard antituberculous therapy combined with adrenal steroids It was hoped that the inclusion of groups receiving ascorbic acid and penicillin, while acting as bases from which to judge any improvement effected by the other two methods of treatment, would shed some light on the role of scurvy and of pneumonia in the pathogenesis of the cases studied

Design of the Trial

From June 1, 1957, to September 26, 1958, all cases of pleural effusion which occurred among the African labourers employed by one group of mining companies were admitted to a central hospital as soon as the diagnosis was confirmed by X-ray examination of the chest and by aspirating 20 ml of fluid from the pleural cavity Referring medical officers were requested to limit the paracentesis to 20 ml so that the possible beneficial effects of removing larger amounts were avoided Although the disadvantages of examining so small a quantity of fluid were realised, it was nevertheless submitted to full examination including a culture and a biological test for tubercle bacilli

On admission to the central hospital a full clinical examination was carried out and another X-ray film of the chest taken for confirmation. Patients showing evidence of pulmonary tuberculosis or of any pathology other than the effusion were rejected. In addition, a few cases with cervical or other adenopathy, abdominal masses, and vitamin deficiency were excluded Consequently those admitted to the trial could be described as suffering from pleural effusion for which no obvious clinical or radiological cause was evident A blood count, erythrocyte-sedimentation rate (E S R) (Wintrobe), Mantoux skin test (Koch's old tuberculin 1/1000), and sputum examinations completed the initial investigations

A panel of 5 doctors allotted a score to the effusion ranging from 1 to 4, depending upon whether it was judged to occupy $^1/_4$, $^1/_2$, $^3/_4$, or the whole of the hemithorax respectively Occasionally it was found necessary to allot $^1/_2$ scores—e g, $2^1/_2$ Minimal effusions were not accepted Sealed instructions for treatment were previously prepared, and as each case was admitted to the trial a member of the hospital clerical staff drew one, so that the following four methods of treatment were allocated at random

Treatment V 500 mg of ascorbic acid intramuscularly daily for the first 14 days only

Treatment P 300,000 units of procaine penicillin intramuscularly twice daily for the first 14 days only

Treatment T 1 g of streptomycin sulphate intramuscularly daily for 8 weeks 200 mg of isoniazid three times daily for 8 weeks

TABLE I—ANALYSIS OF AVERAGE WEIGHTS AND SEDIMENTATION-RATES

Treatment group	Average weight (lb)		Average E S R (mm /hr) (Wintrobe)	
	Initial	Final	Initial	Final
V	127	130	22	14
P	131	131	25	18
T	130	134	29	20
TS	132	138	22	1

Treatment TS Same as treatment T, with the addition of 10 mg of prednisolone (' Deltacortef ') three times daily for 2 days followed by 5 mg three times daily for the remainder of the 8 weeks

All patients received a standard hospital diet and in addition, 3 tablets of vitamin B Co * daily. The period of bed rest varied from case to case depending on the general condition of each patient, but when allowed up, all patients were confined to the precincts of the ward The X-ray examination of the chest and E S R were repeated at the end of 4 weeks, at which time the panel reviewed each patient without knowledge of the type of treatment given This process was repeated at the completion of the trial at the end of 8 weeks

2 patients receiving treatment V and 2 receiving treatment P were withdrawn from the trial and given treatments T or TS because it was felt that they were so ill that the withholding of antituberculous therapy was not justified

Results

75 patients completed the trial, 19 of them having received ascorbic acid (treatment V), 17 penicillin (treatment P), 19 antituberculous drugs (treatment T), and 20 antituberculous drugs combined with steroids (treatment TS)

The pleural fluid was noted to be hæmorrhagic to a greater or lesser degree in 8 cases in group V, 5 in group P, 6 in group T, and 9 in group TS

One patient in group V and another in group P had bilateral effusions, and these were omitted from the statistical analysis, leaving a total of 73 cases for assessment

The sputum examination was negative for tubercle bacilli in all cases entering the trial

The tuberculin skin test was positive in all but 1 case. This patient received treatment TS

In only 1 instance were tubercle bacilli found in the pleural fluid and that to direct examination only He received treatment P Due to an oversight, this result became known only at the completion of his course of treatment

The initial and final average weights and sedimentation-rates appear in table I and suggest an advantage in favour of group TS

In table II are set out the individual details with regard to the extent of the effusion initially, after 4 weeks and after 8 weeks of treatment. It will be seen that the cases were fairly evenly distributed and that the average initial size of the effusions was similar in each treatment group Standard statistical techniques indicate that neither after 4 weeks nor at the completion of the trial was there a significant difference in the rate of clearing of fluid between groups V, P, and T

TABLE III—AVERAGE OVERALL IMPROVEMENT

Treatment	V	P	T	TS	
C_1–C_4	0 639	0 531	0 658	1 885	First 4 weeks
Estimated standard deviation	0 228	0 161	0 184	0 259	
C_4–C_8	0 500	0 219	0 237	0 325	Second 4 weeks
Estimated standard deviation	0 153	0 111	0 072	0 097	
C_1–C_8	1 139	0 750	0 895	2 210	All 8 weeks
Estimated standard deviation	0 189	0 165	0 182	0 218	
Maximum possible average improvement = $\bar{C}_1$	2 583	2 688	2 316	2 735	

On the other hand, a highly significant improvement took place in group TS compared with groups V, P, and T within the first 4 weeks, although no further significant improvement occurred in this group during the subsequent 4 weeks of treatment The various differences and their associated standard deviations are given in table III.

---

* Each tablet contained thiamine chloride 3 mg , riboflavin 2 mg , nicotinamide 20 mg , calcium pantothenate 1 mg , pyridoxin hydrochloride 0 25 mg

TABLE IV—PROPORTION OF COMPLETE RESOLUTIONS

Treatment	No of patients	First 4 weeks			All 8 weeks		
		Cures	% cures	95% confidence interval	Cures	% cures	95% confidence interval
V, P, and T (combined)	53	6	11·3%	4·3% to 23·4%	8	15·1%	6·7% to 27·6%
TS	20	9	45·0%	23·1% to 68·5%	12	60·0%	36·1% to 80·9%
TS minus V, P, and T (combined)			33·7%	9·9% to 57·5%		44·9%	20·9% to 68·9%

The superiority of treatment TS is demonstrated in another way in table IV in which results are judged, not on the relative degrees of absorption of fluid as in table II, but on whether complete resolution of the effusion had occurred or not during the whole of the 8 weeks of the study Because of the similarity of results in groups V, P, and T, these were combined and compared with group TS Analysed in this way 12 out of the 20 cases in group TS resolved completely compared with 8 out of 53 in the remaining 3 groups (2 out of 18 in V, 2 out of 16 in P, 4 out of 19 in T) This difference is again highly significant

Within each treatment group no significant statistical differences were found between the behaviour of those with hæmorrhagic and those with serous effusions

Discussion

Because of certain administrative difficulties it was unfortunately not possible to prolong the trial beyond 8 weeks Even in this short period, however, definite conclusions were reached with regard to the relative values of treatments V, P, T, and TS

It may be inferred from the failure of ascorbic acid to hasten the clearing of the fluid that scurvy is not an important ætiological factor in the cases studied Those receiving penicillin fared no better There was no reason to believe that any patient entering the trial was suffering from, or had recently suffered from pneumonia, and the absence of response to penicillin was additional evidence against this possibility Results with the tetracyclines might have been better, but the inclusion of such a group was not practicable

The group which received streptomycin and isoniazid showed no advantage over groups V or P Although the patients participating in this trial were regarded, for reasons mentioned earlier, as suffering in all probability from effusions of tuberculous origin, this seemingly paradoxical response was not unexpected in view of previous findings In a controlled study, Emerson (1955) showed that whereas antituberculous therapy markedly diminished the incidence of subsequent frank tuberculosis, it had no appreciable effect on the actual resolution of the pleural fluid This conclusion was confirmed by Forgacs (1957) It is suggested that what improvement did occur in groups V, P, and T was due in each instance to natural remission

The addition of adrenal steroids to the streptomycin and isoniazid resulted in a striking reduction in the amount of pleural fluid, and in most instances within the first 4 weeks of treatment The benefit of treatment TS is evident when comparing not only the rate of clearing of the fluid but also the final proportion of complete resolutions The fact that improvement in this group was significant in the first 4 weeks but not in the second can be explained on the grounds that after the initial beneficial effect there was little room for further improvement The superiority of this form of treatment is probably due to the effect of corticosteroids on the allergic component of the disease (Paterson 1917, Petroff and Stewart 1925, Howard and de Veere 1936, Rich 1946), but the use of this drug alone would clearly be inadvisable for fear of reactivating an underlying tuberculous process

The manner in which treatment TS rapidly controlled the constitutional disturbance in seriously ill patients was impressive, pain, fever, and malaise usually disappeared within a few days of starting treatment This was particularly noteworthy in the 4 patients receiving treatment V or P who were removed from the trial on account of marked deterioration and given treatment TS

In 1 of them (originally on treatment V) considerable deterioration was accompanied by the appearance of ascites, and institution of treatment TS resulted in rapid improvement with disappearance of the peritoneal fluid within 5 days It is recognised that the withdrawal of these 4 cases affects the random character of the trial to some extent, but in our judgment it was essential to do so as their lives appeared to be in jeopardy If anything, the withdrawal of these cases lessened the statistical advantage of group TS to some extent

The clinical response to treatment T was also noticeably superior to that of treatments V and P, although not to the same extent as treatment TS

Also of interest is the fact that a number of patients (not connected with the trial) with pericardial and peritoneal effusions of presumably tuberculous origin, were given treatment TS with equally beneficial results

It is a matter for regret that since these patients were migrant labourers a comprehensive follow-up study could not be carried out

Summary and Conclusions

A therapeutic trial was designed to evaluate 4 different methods of treatment of pleurisy with effusion in African labourers employed in the goldmining industry on the Witwatersrand The treatments were (*a*) standard antituberculous treatment, (*b*) standard antituberculous treatment with the addition of adrenal steroids, (*c*) ascorbic acid, and (*d*) penicillin

Antituberculous drugs combined with adrenal steroids proved to be much superior to the other methods

Scurvy and pneumonia do not appear to be significant ætiological factors in pleural effusions occurring in this population

Our thanks are due to Dr I Webster, of the Pneumoconiosis Research Unit of the South African Council for Scientific and Industrial Research, for performing the investigations on the pleural fluid, and to the South African Institute for Medical Research for the other laboratory investigations We are grateful to The Upjohn Company for the generous donation of 'Deltacortef'

SEVERE HYPERSENSITIVITY TO SULPHAMETHOXYPYRIDAZINE

G P MAHER-LOUGHNAN
M A , D M Oxon
CONSULTANT PHYSICIAN

D C TULLIS
M B St And
MEDICAL REGISTRAR

COLINDALE HOSPITAL, LONDON, N W 9

IN the case described here the patient showed extreme hypersensitivity to sulphamethoxypyridazine, a long-acting sulphonamide preparation

Case-report

A married woman, aged 41, had for fourteen years had rheumatoid arthritis, for which over the past two years she had been having small daily doses of cortisone In November, 1958, because of a productive cough and lassitude she was seen at a chest clinic and was thought to have tuberculosis While investigations were continuing, a course of oxytetracycline, to be followed by a course of sulphamethoxypyridazine (' Lederkyn ') 0 5 g daily, was prescribed

After the patient had taken 3 g of this sulphonamide, a generalised erythematous rash developed Her doctor was called in and promethazine hydrochloride tablets were prescribed As the irritation persisted she was admitted to hospital

Examination and Treatment

On admission the patient was pyrexial, there were physical signs of bronchitis, and she had a generalised urticarial rash with severe œdema of the face She was considered to have a drug sensitivity reaction and the promethazine hydrochloride was continued Next day the urticaria had progressed to vesiculation, later the vesicles coalesced so that the entire skin surface of the body, apart from the scalp, was converted into a fluid sac Promethazine hydrochloride was discontinued and prednisone started immediately, 60 mg was given in the first twenty-four hours, and subsequently 40 mg daily until the drug was " tailed off "

A chest X-ray revealed right basal pneumonia, and erythromycin was started in view of the finding of pneumococci in the sputum culture Later, because of changes in the flora, she was given courses of chloramphenicol and tetracycline

Management

Although the patient's general condition was very poor, an adequate intake of fluids was maintained orally, the serum-proteins and electrolytes on repeated estimations remained within normal limits The question of transfusion of plasma and/or fresh whole blood was raised, but, because of the congestion of the lungs and the danger of pulmonary œdema, action was delayed.

Nursing became more difficult as the entire skin surface peeled off, leaving only raw dermis, the mucous membranes of the mouth and tongue also sloughed off

A ' Ripple ' bed, as used for poliomyelitis, was obtained Non-greasy tulle-gras dressings were considered necessary for nursing and handling this patient, the problem was how to apply and maintain such extensive dressings The condition of the lungs in such a gravely ill patient precluded general anæsthesia or even basal narcosis It was therefore decided to attempt to produce analgesia and, if possible, amnesia by hypnosis

The patient proved an excellent subject, possibly because she was in a state of shock She rapidly reached a deep somnambulistic level, and surface analgesia was obtained She was moved to the theatre and full dressings were applied, catatonia, which is usual in deep hypnosis, proved most valuable for limb dressings, the patient maintaining her limbs upright and unsupported indefinitely The theatre sessions proved lengthy (approximately one and a half hours) but the patient's condition remained good throughout these periods

After four days of prednisone, corticotrophin 40 I U was given daily in addition, as the exudative process was not completely under control

Progress

On the eleventh day the patient showed some signs of improvement and, although the tongue and buccal mucous membranes were still raw (despite mixed supplementary vitamins), she could eat pureed foods, but it was not until two or three days later that the ultimate prognosis seemed more hopeful On the seventeenth day a chest X-ray showed that the lung fields had cleared

The more deeply affected areas on the buttocks and thighs could now be treated by exposure to the air and new skin and nails gradually grew The scalp being unaffected, there was no loss of hair The skin, which had completely regenerated in six weeks, was extensively and deeply pigmented

The prednisone was " tailed off " and discontinued after seven weeks, and the corticotrophin was stopped a week later, without any upset

Tests for Sensitivity

Skin tests with all the drugs the patient had taken before admission were negative These drugs were then given orally in small test doses (quarter normal dose)

Six hours after the patient was given 125 mg of sulphamethoxypyridazine she felt her joints becoming stiff and painful, her temperature rose, and her face became flushed and œdematous She was immediately given 40 I U corticotrophin and 20 mg prednisone When, after eighteen hours, symptoms subsided the steroids were slowly withdrawn

The other drugs were given in test doses without any reaction and the patient was discharged after three months with new nails and a new skin (the pigmentation fading gradually) Although there were no arthritic symptoms, the latex fixation test was positive

A " pink card " was given to this patient stating that she had had corticosteroids and that she was hypersensitive to long-acting sulphonamides The patient's impatience to go home precluded desensitisation to the offending drug

Discussion

Sulphamethoxypyridazine is reported to be as effective as sulphadiazine (Terrell et al 1957), and, because of its very slow renal excretion, adequate blood-levels are maintained for long periods on relatively small doses Side-reactions are slight and uncommon Vinnicombe (1958) reported that no serious sensitivity reaction had been reported

Davis and Tachjian (1956) reported an extremely severe general reaction to sulphafurazole which had many of the features of our case, and which also required intensive treatment with steroids and antibiotics A less severe reaction to sulphadimidine (Fox 1955) started after five days' treatment and ended with pigmentation of the skin at the sites of the original bullous lesions

In our patient the recently discontinued steroid therapy probably increased the severity of the reaction The use of hypnosis in the management of this patient is of interest since this case resembled in many ways one of extensive second-degree burns Bayles (1959) has advocated the more general use of hypnosis in cases of severe burns The advantages of a deep trance state over general anæsthesia are that the patient remains fully cooperative, the cough reflex is retained, while analgesia and amnesia for dressing sessions are assured

We should like to express our admiration of Sister S Jarrett and her staff whose patient and tireless nursing played a major part in the recovery of this patient

RENAL HÆMODYNAMICS IN HEPATIC CIRRHOSIS

KEMAL H. ÖNEN
M.D. Istanbul
LECTURER, DEPARTMENT OF THERAPEUTICS AND PHARMACOLOGY, FACULTY OF MEDICINE, UNIVERSITY OF ISTANBUL

FACTORS such as diminished osmotic pressure of plasma and raised portal pressure are known to be insufficient to explain the œdema and ascites of hepatic cirrhosis. Recent views have given a special importance to adrenocortical steroids and renal factors, and we have studied changes in renal hæmodynamics in patients with cirrhosis.

In 17 cirrhotics the following were studied: (a) glomerular filtration-rate (G.F.R.), (b) renal plasma flow (R.P.F.), (c) renal reabsorption of sodium, and (d) daily urinary excretion of total formaldehydogenic steroids.

15 of these 17 patients were men and 2 were women. 3 normal persons were also studied for comparison. The investigation continued for from 20 to 40 days and was divided into two periods: during the first the patients and controls had a diet in which 6 g. of sodium chloride was added daily to their standard high-protein low-fat diets for at least 7 days. During the second period the patients and the normals returned to a low-salt regime. During both periods all five observations mentioned above were studied.

According to the clinical picture, the 17 patients were divided into two groups: (a) progressive and decompensated (12), and (b) regressive (5).

We measured G.F.R. with mannitol, and R.P.F. with p-aminohippurate (Page and Corcoran 1949). Both were given into a vein in continuous saline infusion throughout the examinations. Sodium was measured in urine and plasma by uranyl acetate (Hinsberg and Lang 1951). Total formaldehydogenic steroids in the urine were estimated by a modification of the periodic-acid oxidation method (Rivoire and Paszkowski 1952).

In cases 4, 7, 9, and 16 it was not possible to have a low-salt period.

Results

(a) In 9 of the 12 cases in the first group, we found obviously low values for G.F. (56·5 ml. per min.) and R.P.F. (249 ml. per min.). Filtration fraction (F.F.) was 0·22 in this group. According to these values, G.F. and R.P.F. were reduced to less than half normal. In the other 3 cases the G.F. and R.P.F. were normal or slightly reduced. Enormous ascites was present in these 3 cases, which suggests that ascites plays little part in decreasing the renal circulation.

In the first group, the renal excretion of sodium was strikingly low (0·53% of filtered sodium).

(b) Results in the second group were: mean values for G.F. and R.P.F. 101 ml. per min. and 535 ml. per min. respectively, F.F. 0·18, renal excretion of sodium 1·1%.

Renal hæmodynamic values were more or less the same during both low-salt and extra-salt periods in cirrhotics.

(c) The values for total formaldehydogenic steroids in urine were normal or slightly low in both groups (1·83 mg. per day in the first and 2·2 mg. per day in the second). The data are shown in the tables.

DISCUSSION

The results of different investigators who have studied this subject do not all agree. In 3 cases with ascites Patek et al. (1948) found normal values for G.F. Goodyer et al. (1950) also observed normal values for G.F. in 4 out of 5 cirrhotics, and Epstein et al. (1950) recorded normal values for G.F. in cirrhotics. On the other hand, Leslie et al. (1951) found low values for G.F. and R.P.F. in cirrhotics with considerable ascites and œdema.

These striking differences suggest that renal hæmodynamic changes are important in fluid accumulation in cirrhosis. In the cases with low hæmodynamic values sodium clearances and total daily renal sodium excretion were significantly lower than when the renal hæmodynamic values were normal. It seems reasonable to say that renal circulatory insufficiency and defects in renal salt excretion run parallel, and that is a definite finding in decompensated cases.

The connection between low G.F. and diminished salt excretion was demonstrated by Merrill (1946) in congestive cardiac failure, and confirmed by others. We also recorded similar findings, particularly very high F.F. values, in congestive heart-failure (Önen 1951), and we emphasised the importance of high F.F. values and the consequent high osmotic pressures in the efferent arterioles. It seems logical that excessive reabsorption of sodium also takes place in hepatic cirrhosis, at least in its later stages.

The causes of this "renal hæmodynamic insufficiency" are debatable. At first sight ascites could be taken as a cause of decreased G.F. and R.P.F., but neither clinical nor experimental observations support this. Results in 3 cases in the first group and all in the second group with ascites make this possibility unlikely.

We could not measure aldosterone excretion in the urine. Apart from aldosterone's effects on salt excretion, the diminution of G.F. and R.P.F. may reduce renal clearance of aldosterone itself, and it would seem logical, therefore, to estimate the plasma-aldosterone as well in cirrhosis.

SUMMARY

Renal hæmodynamics were studied in 17 cases of portal cirrhosis. In 12 progressive and severely decompensated cases hæmodynamic figures were strikingly low. On the other hand in 5 mild and regressive types of cirrhosis, glomerular filtration-rate and renal plasma flow were normal.

Total urinary formaldehydogenic steroids were normal or slightly reduced in both groups

The possible role of renal hæmodynamics in salt and water retention in cirrhosis are briefly discussed

I am indebted to Prof Dr Sedat Tavat, director of the department of therapeutics and pharmacology, and Prof N Kastarlak, Prof R Garan, and Prof S Artunkal for their valuable suggestions and kind help

LECTURER IN MIDWIFERY, UNIVERSITY OF ABERDEEN

E A F Priest
M B Aberd , M R C P
ASSISTANT CARDIOLOGIST, ABERDEEN ROYAL INFIRMARY

Hypoglycæmia associated with fibrosarcomata and sarcomata is rare, and only 8 examples have been reported (Doege 1930, Seckel 1939, Arkles 1942, Hines 1943, Skillern et al 1954, Silvis and Simon 1956, Holton 1957) The case described here is believed to be the first recorded in Britain

Case-report

A married woman, aged 56, para 3, was admitted to a medical ward of the Aberdeen Royal Infirmary on Oct 1, 1957 Thirteen days previously she had been found unconscious in bed and had then been admitted to the local cottage hospital Spells of unconsciousness had continued after admission and had become longer in duration before her transfer to Aberdeen

Her previous medical history had been uneventful, apart from rheumatic fever at the age of 26 She had been breathless on exertion for a few months, and about five weeks before admission to hospital began to have attacks of nocturnal sweating, which usually wakened her at about 4 A M , these passed off spontaneously, and she felt well during the day and was able to do her housework She had noticed her abdomen becoming larger during the previous two months and did not think she had become thinner

Soon after admission, while being examined she became very drowsy and fell asleep She was rather obese The heart and lungs seemed normal. The pulse-rate was 88 and the blood-pressure 200/95 m m Hg There was moderate sacral and ankle œdema The urine was sugar-free and seemed normal in other respects A large, fixed, irregular, hard mass which was not tender filled the pelvis and the lower abdomen up to the umbilicus Although there was no obvious ascites malignant ovarian tumour was provisionally diagnosed

Two hours after admission the patient became very restless and confused, and sweated profusely Paradehyde 8 ml and phenobarbitone sodium gr 3 were given by intramuscular injection On the following day at 1 P M the blood-sugar content was found to be 37 mg per 100 ml 50 ml of 50% dextrose solution was given intravenously, and the patient immediately regained consciousness for the first time since her initial examination. Repeated blood-sugar examinations confirmed that the unconsciousness was due to hypoglycæmia, which could be controlled by intravenous and oral glucose Electrocardiography examination showed myocardial changes which were thought to be due to the hypoglycæmia

Other laboratory investigations gave the following results hæmoglobin 83% (12 3 g per 100 ml Eel electric colorimeter 100% = 14 6 g per 100 ml), white blood-cells 8000 per c.mm., plasma-CO_2 64 vols % (22 7 mEq per litre), serum-potassium 10 9 mg per 100 ml (2 8 mEq per litre), serum-sodium 325 mg per 100 ml (141 4 mEq per litre), serum-chloride 600 mg per 100 ml (103 mEq per litre), serum-phosphate 2 9 mg per 100 ml. (1 68 mEq per litre), cerebrospinal fluid protein 30 mg per 100 ml , cells none, Wassermann reaction negative, Thymol turbidity 2 units, serum-alkaline-phosphatase 13 5 King-Armstrong units, serum-bilirubin 0 3 mg per 100 ml

Two conditions were considered as possible causes of the hypoglycæmia (1) islet-cell tumour of the pancreas, and (2) fibroma or sarcoma causing hypoglycæmia (Conn and Seltzer 1955) It was decided to perform laparotomy on Oct 7, 1957

Preparation for Operation

In order to prevent hypoglycæmia during the operation a cardiac catheter was inserted into the superior vena cava the evening before the operation, and 2 pints of 50% dextrose solution was infused in the next twelve hours The blood-sugar level was maintained at about 190 mg per 100 ml

Conn and Seltzer (1955) recommended administration of the corticotrophin to prevent the " idiopathic hyperthermia " which caused 5 out of 18 postoperative deaths in a series of cases reported by Howard et al (1950) 50 units of aqueous corticotrophin was therefore given eight-hourly for twenty-four hours before operation.

Operation

A large retroperitoneal tumour was found It seemed to originate and be fixed to the area of the right pubic ramus, and extended medially between the bladder and the uterus, the latter being normal in size and behind and below the tumour Both fallopian tubes and ovaries were normal

A line of cleavage was found in the capsule of the tumour and the mass was enucleated The tumour was very vascular, and considerable bleeding occurred The mass was very adherent to the bladder, and while it was being separated a small hole was torn in the bladder wall, this was repaired in the usual manner In order to control the bleeding subtotal hysterectomy was also performed The raw area, left after removal of the tumour, was covered with peritoneum and a drain inserted into the pouch of Douglas

The liver was normal to palpation, but a small hard nodule was felt in the pancreas where it crossed the aorta This was not considered to be significant The drain from the pouch of Douglas was brought out through the abdominal incision, which was then closed A self-retaining catheter was inserted into the bladder

Postoperative Course

3 pints of blood was given during and after the operation and followed by intravenous saline solution at a slow rate of flow Blood-sugar estimations were performed hourly during the first day and thereafter at longer intervals The blood-sugar level remained within normal limits, no additional glucose being required On the second postoperative day the intravenous infusion was stopped and fluids were given by mouth. The serum-potassium was 10 0 mg per 100 ml (2 5 mEq per litre) on the second day after operation, and therefore 1 g potassium chloride in 1 oz fruit juice was given four-hourly till the seventh day when the serum-potassium was 20 mg per 100 ml (5 mEq per litre) In view of the malignancy of the tumour the chest was X-rayed, but no metastases were detected A course of deep X-ray therapy was given to the pelvis, and the patient was discharged from hospital on Nov 13, 1957 When last seen, in February, 1959, she was very well, with no symptoms of hypoglycæmia and no evidence of recurrence of the tumour A mid-day blood-sugar estimation showed the level to be 85 mg per 100 ml

Pathological Report

The tumour mass measured 10 in. × 7 in × $4^1/_2$ in. (25 4 cm. × 17 7 cm × 10 4 cm) and weighed 2750 g

Histology (Prof J S Young) —" The tumour presents the histological characteristics of a sarcoma The predominant tumour cell is elongated and possesses a vesicular nucleus which is rod-shaped with rounded ends Throughout the section oval or spheroidal cells, always with vesicular nuclei, are observed, but it may be inferred that such variations in shape are attributable to the different planes of section in which the cells have been cut. In particular there is no reason to suspect that the spheroidal cells are neoplastic epithelial cells Mitoses are present but they are so relatively scanty as to suggest that the grade of malignancy is likely to be low In several of the sections it is evident that the tumour is invested by a substantial fibrous capsule With regard to its histogenesis the growth is most probably a leiomyosarcoma despite the fact that neither fasciculation nor pleomorphism of the tumour cells is a conspicuous feature "

Discussion

Several types of large tumours in various sites are known to produce hypoglycæmia

Four adrenal tumours associated with hypoglycæmia have been reported (Anderson 1930, Lawrence 1937, Broster and Patterson 1948, Staffieri et al 1949) Three of these tumours appeared to arise in the adrenal cortex, and microscopically the cells were similar to those seen in adrenocortical carcinoma The case reported by Lawrence had, in addition to hypoglycæmia, features suggestive of Cushing's syndrome, and that reported by Broster and Patterson had marked virilism The hypoglycæmia in these cases may have been due to adrenal failure or to a substance secreted by the tumour

Three patients had sarcomatous tumours in the thoracic cavity (Arkles 1942, Doege 1930, Skillern et al 1954) One had a fibromatous tumour of the liver causing hypoglycæmia (Seckel 1939) The remaining reports are of sarcomatous or fibrosarcomatous tumours situated in the abdomen (Hines 1943, Silvis and Simon 1956, Skillern et al. 1954, Holton 1957) These abdominal tumours were all situated in the upper abdomen, whereas in our case the tumour originated from the pelvis

When the tumours are removed surgically the hypoglycæmia disappears, to return if the tumour recurs In the case reported by Arkles (1942) the tumour recurred after seven years, and this resulted in a return of the hypoglycæmia and death, in Hines' (1943) case recurred after two years, with metastases and hypoglycæmia, in Holton's (1957) case the interval between operation and recurrence with death from hypoglycæmia was five years In the other reported cases insufficient time had elapsed for the final outcome to be known On the whole it seems that the degree of malignancy in these tumours is usually low, so recurrence is delayed for some years and in the interval the patient remains well Microscopically the tumours are mainly sarcomata with round and/or spindle cells

Those occurring in the adrenal gland, which are really a different entity, are similar to those found in adrenal carcinoma Skillern et al (1954) found blue-staining beta granules in the cytoplasm of the occasional round cell in one of their cases They considered these to be insulin-secreting, similar to these found in the pancreas

The main problem posed by these tumours is the cause of the hypoglycæmia Four main hypotheses have been put forward

1 These tumours secrete insulin or some other substance which lowers the blood-sugar level Seckel (1939) and Howard et al. (1950) performed insulin assay of the tumours in their cases but found none. Although insulin assays were not performed on their cases, Skillern et al (1954) believed that the diagnosis of insulin-producing neoplasm was justified by the demonstration in one of their cases of round cells resembling the beta cells of the pancreas, the demonstration of blue-staining granules in an occasional round cell in the tumour of their second patient, and the complete relief of hypoglycæmia by extirpation of the tumour

Without insulin assay it is not possible to say whether the tumours produce insulin or not No beta granules were found in the tumour cells of our case Possibly the spindle cells may have originated from ectopic pancreatic islet tissue, but this cannot be proved.

2 The tumour utilises glucose excessively, thus causing hypoglycæmia This seems a possible explanation, but many patients with large tumours histologically similar to the case reported do not have hypoglycæmia Increased uptake of glucose by the tumour would account for the low serum-potassium levels preoperatively in this case, the potassium migrating into the cells with the glucose

Woodward and Fry (1932), however, found that tumour tissue can glycolyse carbohydrate more rapidly than normal tissue and that the blood-sugar level is raised in cases of cancer It might be assumed that a rapidly growing neoplasm induces increased glycogenolysis, thus elevating the blood-sugar as long as stores are not depleted. When stores of glycogen are used up hypoglycæmia might ensue

3 Coincident presence of a pancreatic adenoma causes the hypoglycæmia This was ruled out in the present case, although at operation a small hard nodule was felt in the pancreas where the gland crosses the aorta Before the pedicle of the large tumour was clamped a blood-sugar reading was 250 mg per 100 ml Forty minutes after clamping, and while intravenous glucose 50% was still being administered, the blood-sugar rose by 86 mg per 100 ml It was therefore considered that the large tumour had been causing the hypoglycæmia. This valuable method of assessing the effect of removal of the tumour on the blood-sugar before closing the abdomen was suggested by McMillan and Sheibe (1951) A pancreatic adenoma could finally be excluded in this case by the patient's subsequent progress

4 The hypoglycæmia is due to stretching or disruptive effects of unknown receptors in the abdomen Evans et al (1931) showed in the cat that disruption of the sympathetic nerve-supply to the liver causes hypoglycæmia Rosenfield (1949) postulated, in a case of pseudomyxoma peritonei with hypoglycæmia, that, since large amounts of tumour mass were present in the area of the cœliac ganglion and the right splanchnic chain, the hypoglycæmia might be due to interference with the sympathetic nervous system

The diversity of pathological picture in the reported cases is against the hypothesis that the tumours produce insulin or an insulin-like substance The cause of the hypoglycæmia must necessarily be in doubt until insulin assays have been more widely performed

We wish to thank Prof Dugald Baird and Dr R J Duthie for permission to publish this case and for helpful advice, Prof J S Young for the histological report, and Mr A W Wilkinson for his help in the management of the patient

Preliminary Communications

TRETAMINE IN THE TREATMENT OF INOPERABLE LUNG CANCER

THE first use of tretamine (2 4 6-triethyleneimino-s-triazine, triethylene melamine [T E M]) in the control of clinical malignancy[1] followed its release for research purposes by Imperial Chemical Industries as the result of observations[2,3] on the inhibitory action of this and related compounds on the growth of experimental tumours Other clinical reports[4] followed independent parallel discoveries made at the Sloan-Kettering Research Institute, New York

Experimental work on mice[5] showed that tretamine had very considerable activity against sarcoma 180 and lymphosarcoma L 1 The best response was obtained by large doses at infrequent intervals

In 15 cases of lung cancer treated with this drug[6] 4 showed marked clinical improvement but no radiological change In this and most subsequent reports the method of dosage has been frequent small doses over a period of a few weeks Most workers have found it to be very toxic on the hæmopoietic tissues when so used Wilkinson[7] regarded it as the most toxic of all agents he had tried

During the period July to November, 1959, 43 patients with advanced inoperable lung cancer have been treated with tretamine Untreated the majority of these patients would have been dead within three months and many earlier than this After some experiment a pattern of dosage that has given very encouraging results has been worked out 30 patients have shown subjective improvement and in 10 of these very marked to complete regression of the tumour has occurred

In 4 cases the chest X-ray has returned to normal or near normal and it is these 4 results that have stimulated this preliminary report Radiologically each patient had a large mass at one or other lung root with considerable enlargement of the superior mediastinal shadows Tumour tissue was obtained from the bronchi or from neck glands or from both sites and in each instance was reported as an undifferentiated carcinoma Additional details are given in the table and X-rays representative of the series are shown in figs 1 and 2

Treatment of these 4 cases consisted of one or two large doses of tretamine given intravenously, with a total dose of 15 to 30 mg This dose may be followed by severe nausea for twenty-four hours Within three days subjective improvement was evident, and chest X-ray done routinely on the fifth day showed evident shrinkage of the tumour mass This shrinkage continued over the next three weeks and at the end of a month the chest X-ray had returned to normal

Fig 2—Case 2 (a) Day before treatment; (b) five days after 30 mg tretamine, the chest was not aspirated and no other treatment was given; (c) one month later

DETAILS OF 4 CASES OF INOPERABLE BRONCHIAL CARCINOMA-TREATED WITH TRETAMINE

Case	Age (yr)	Sex	Dose of tretamine	Lowest white count (per c mm)	Lowest platelet-count (per c.mm)	Clinical features	Result
1	67	M	10 mg 10 mg	1700	69,000	Left hilar shadow Left recurrent nerve palsy Bed-ridden by weakness Stridor	X-ray normal at one month Voice normal at three months when still completely well
2	53	M	30 mg	840	25,000	Superior vena caval obstruction Dysphagia Bilateral neck glands Secondary in 7th thoracic vertebra	X-rays normal at one month except for translucency in vertebra
3	62	M	30 mg	1200	10,000	Stridor Early superior vena caval obstruction Gross œsophageal distortion Large mass left hilum	X-rays normal at three weeks
4	57	M	30 mg	500	12,000	Complete collapse left lung Left hilar mass Slight stridor	X-ray normal at one month

Of the other 6 patients whose tumours have undergone marked regression, 3 died within twelve days after the start of treatment, owing to hæmorrhage from the tumour which had undergone necrosis, the platelet-count was at a safe level at the time of these hæmorrhages

The remaining patients were treated because of metastases from bronchial tumours previously removed. Only a clinical assessment of the regression of these metastases could be made since they were not radiologically visible The patients, however, are all well and symptomless and the follow-up results are awaited

In every case there has been a depression of the white blood-cells and the platelets The white blood-count falls to its lowest level about the twelfth day and if below 500 at this time prednisolone and penicillin have been given for a period of seven to ten days The platelet-count has been more variable and usually reaches its lowest point about the fifteenth day In 2 patients a slight purpuric rash occurred with a platelet-count of less than 25,000 per c.mm Both were given a transfusion of fresh blood Some of the early cases were treated with repeated small doses of tretamine, in 3 of these severe purpura occurred and blood-transfusion was urgently needed It is considered advisable to watch very carefully for evidence of purpura from the twelfth day onwards It was found expedient to do blood and platelet counts on alternate days until a moderate pancytopenia was present and then daily until the counts had returned to near normal

Pyridoxine (100 mg intramuscularly once daily) and dimenhydrinate (' Dramamine ') (50 mg six-hourly) has been given four hours after tretamine to control the nausea which occurs on the first day of treatment, and ' Villescon ' (two tablets twice daily) has helped to restore a more than normal appetite by the fifth day of treatment

Tretamine in a single dose of 20–30 mg (0 35 mg per kg) intravenously should be tried in inoperable undifferentiated cancer of the lung The pancytopenia is manageable with prednisolone and penicillin and occasionally blood-transfusion We do not yet know the duration of remission that this will produce nor have we any information on the effects of a second course of treatment. The problem of hæmorrhage from necrotic tumour needs to be solved, and the possible place of this drug in combination with surgical excision must also be considered

We should like to acknowledge with thanks generous supplies of tretamine provided for this investigation by Imperial Chemical Industries Ltd , and much useful information from Dr A L. Walpole, of I C I Research Laboratories

SERUM-5-HYDROXYTRYPTAMINE LEVELS FOLLOWING EXPERIMENTAL INCREASE IN GASTROINTESTINAL ACTIVITY IN MAN

THERE are good reasons for believing that much of the blood-5-hydroxytryptamine (5-H T) is derived from the enterochromaffin cells of the gastrointestinal tract Haverback and Davidson [1] have demonstrated low levels in a patient with extensive resection of large and small bowel By means of a cardiac catheter, Erspamer and Testini [2] found more 5-H T in the hepatic vein than in the inferior vena cava of patients Experiments on the guineapig intestine [3] have shown that increased intraluminal pressure releases 5-H T from the gut, and Kowlessar et al [4] have reported an increase in the excretory product of 5-H T in the urine of patients with diarrhœa due to non-tropical sprue It is possible, therefore, that 5-H T has some role in maintaining the motility of the intestine and that during increased small-bowel activity a larger quantity is released into the circulation The following experiments were conducted to test this hypothesis

METHODS

Volunteers were obtained from a group of healthy medical students Serum-5-H T was extracted by the method of Hardisty and Stacey [5] The extracts were assayed on rat uteri

EFFECTS OF ADMINISTRATION OF CARBACHOL AND MAGNESIUM SULPHATE TO VOLUNTEERS

Treatment	No of subjects	No of abdominal sounds per min. (mean ± S.E)		Serum-5-H T (μg per litre) (mean ± S.E)		Mean of differences in serum-5-H T (μg per litre) (mean ± S.E)	Significance of mean difference (P)
		Before treatment	After treatment	Before treatment	After treatment		
Carbachol 0 2 mg subcutaneously	5	7 ± 3	69 ± 17	139 ± 1 6	182 ± 12 5	43 ± 10 8	0 02
Magnesium sulphate 30 g orally	5	5 ± 1 3	47 ± 26	184 ± 25 3	202 ± 21	18 ± 0 4	0 02
Exercise (350 kg per min. for 15 min.)	5			180 ± 32	175 ± 39	−5 ± 152	0 8

[4] Kowlessar, O D , Williams, R C , Law, D H , Sleisinger, M H *New Engl J Med* 1958, 259, 340

[5] Hardisty, R M , Stacey, R S *J Physiol* 1955, 130, 711

pretreated with stilbœstrol, using automatic apparatus (Casella electronics) adapted for superfusion Immediately after withdrawing the first blood sample from the volunteer, carbachol 0 2 mg was injected subcutaneously, or magnesium sulphate 30 g in 250 ml water was ingested orally Increased motility of the bowel was estimated by recording on tape the noises produced by the intestine, a conventional tape-recorder was employed with its microphone suitably protected from extraneous sounds and applied to the abdominal wall The electrical output of the tape was amplified and the pulses were then counted on a scaler This method is similar to that used by Farrar and Ingelfinger[6] The second blood sample was taken one hour after the injection of carbachol and four hours after the ingestion of magnesium sulphate Three or four four-point assays were performed on each blood sample

RESULTS

The results are summarised in the accompanying table Fifteen subjects were studied Of five treated with carbachol, all showed an increase in the serum-5-H T The mean increase was 43 μg per litre and was significant at the 2% level of probability The five subjects who ingested magnesium sulphate (30 g) showed less increase in motility and a smaller rise in 5-H T of 18 μg per litre, which was still large enough to be significant at the same level of probability The changes in serum-5-H T are not simply due to repeated blood sampling as is shown by the control subjects, who received no intestinal stimulant but instead took a short period of exercise between the two blood samples In these subjects there was no significant difference between the 5-H T levels in the first and second samples, indicating that venepuncture did not influence the 5-H T levels

COMMENT

Carbachol and magnesium sulphate are both known to increase intestinal motility, and, in view of the increased intestinal sounds, they evidently did so in the present experiments Both drugs also raise the serum-5-H T significantly It is unlikely that they have another common site of action besides the intestine, and it is therefore reasonable to conclude that the 5-H T was liberated in association with increased intestinal activity

DEVICE FOR REMOVING AN OPEN SAFETY-PIN FROM ŒSOPHAGUS OR BRONCHIAL TREE

AN open safety-pin, with point and head upwards, always presents a grave problem Attempts to remove the pin by direct traction lead almost invariably to puncture or tearing of the viscus, and fatal mediastinitis has often been recorded To try to reverse the pin so as to bring the loop-end upwards is equally dangerous The victims are usually young children, but the accident of swallowing an open safety-pin may happen in older people, and especially in the mentally afflicted

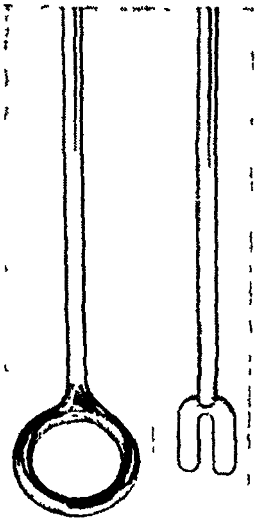

Fig 1

The three photographs are largely self-explanatory The ring and fork (fig 1), which I devised and first used some 10 years ago, have proved invaluable Until recently my instruments were home-made, but they have now been produced, in two sizes and slightly different shapes for adults and children, by the Genito-Urinary Manufacturing Co, 28a, Devonshire Street, London, W 1 The instrument for children is small enough to go through a child-size œsophagoscope or bronchoscope

The diagnosis is confirmed by plain X-ray examination (The pin is found in the œsophagus far more commonly than in the trachea or bronchus) Under general anæsthesia, an appropriate œsophagoscope or bronchoscope is passed With the œsophagoscope a Barlow's high-power distally illuminated telescope is used to estimate the degree of œdema and the exact site of the loop of the pin With the bronchoscope, which is distally illuminated, a direct-vision telescope is used. All mucus, food, &c, is aspirated, leaving the field of vision as clear as possible

When the loop is clearly seen—and this is usually simple—the telescope is withdrawn, and the ring (which is fixed obliquely on the shaft) is passed beyond the pin-loop and brought up to engage it gently but firmly (fig 2) If there is any difficulty, the telescope is passed above the ring to give an excellent close-up view Once the ring is engaged, the fork is passed (again followed by the telescope if necessary) and applied directly on to the pin-loop Holding the ring firmly, pressure is applied to the fork, and the safety-pin is easily closed (fig 3) The ring, fork, and pin are then drawn into the endoscope, and all the instruments are withdrawn together

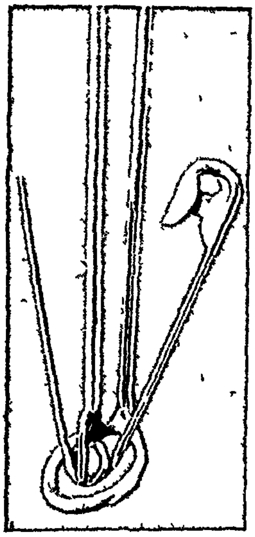

Fig 2

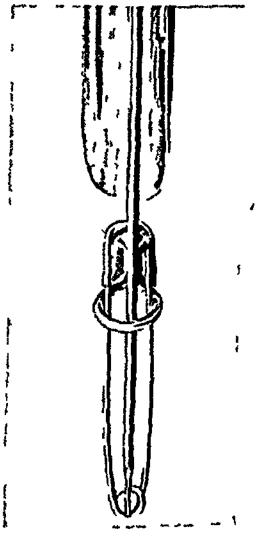

Fig 3

This procedure has never proved fatal nor has it caused serious after-effects

ŒSOPHAGEAL MICROPHONE

THE auscultation of heart and breath sounds during operation is very desirable, but it necessitates strapping a chest-piece on to the patient During cardiac and thoracic surgery, when it would be of most value, this is impossible

In 1954 Code Smith[1] of Toronto described a method of modifying the chest-piece of the conventional stethoscope by attaching a catheter with a rubber diaphragm, and passing it into the œsophagus, so allowing heart and breath sounds to be heard during operation. We have improved on this by attaching a tiny microphone to the end of a catheter, which is then connected to an amplifier, the 'Soniscope',[2] and so to a loudspeaker ('Cardiophone') The controls of the soniscope permit high-pitched or low-pitched sounds to be excluded at will, and by sliding the catheter up or down the œsophagus, heart and breath sounds can be heard

---

[1] Smith, C *Anesthesiology*, 1954, 15, 566

The catheter, with its terminal microphone, is best introduced into the œsophagus with the aid of a Macintosh laryngoscope and a Magill's forceps when the patient is fully relaxed before endotracheal intubation. It may also be used with an oropharyngeal airway and face mask. Heart sounds are best heard in the adult at 23–25 cm. from the incisor teeth

The œsophageal microphone allows anæsthetist and surgeon continuous or intermittent monitoring of heart and breath sounds during operation. It is especially valuable for detecting early evidence of cardiac irregularities or accumulation of bronchial secretions It is also useful in teaching

The 'Soniscope' and 'Cardiophone' are made by Faraday Electronics Ltd, 65, Fairview Road, London, S W 16

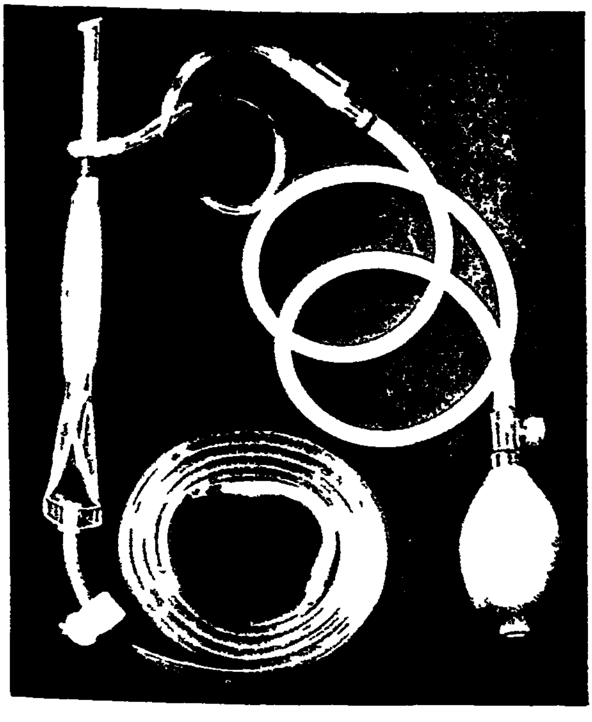
A SIMPLE PUMP FOR INTRAVENOUS INFUSION

Particularly since the introduction of disposable plastic infusion sets, neither the Higginson syringe nor the mechanical roller pump has proved consistently satisfactory The Higginson syringe has only one non-return valve, which tends to leak back, and the roller pump requires two hands for manipulation

The new pump comprises a length of polyethylene tubing (bore IV/3) with a bulb and valve-control screw from a standard sphygmomanometer at one end. This unit contains both a simple non-return valve and a modified sleeve valve, which together completely prevent leakage At the other end of the tubing is a Luer adaptor which fits the air inlet of a disposable infusion set (see figure)



This apparatus is light and easy to control, and, because the valves prevent leak back, the pump tubing need not be clipped off High pressure can be built up in the bottle, and when this is empty and the metal needle is exposed, the screw valve may be operated to release any residual pressure, thus avoiding the danger of air-embolism

MEDICAL OFFICERS OF SCHOOLS ASSOCIATION

Boxing was discussed by the Association at a meeting in London on Jan 7

Dr **Macdonald Critchley** spoke of the injuries to the brain that result from head blows The commonest type of knock-out is now thought to be due to concussion of the medullary centres in the midbrain The extreme hypotonus, short duration of unconsciousness, and usually full recovery make it a unique response to injury Even if not very much harm is done in ninety-nine out of a hundred knock-outs the fact remains that a neurologist holds the central nervous system in some respect However doubtful the harm may be in some instances, it is beyond belief that such treatment is good for the brain There is no question whatever but that harm is likely to result from repeated injuries Speaking of serious damage to the second most delicate organ at risk—the eye—Dr Critchley mentioned Doggart's[1] work especially Although punch-drunkenness is practically limited to the professional boxer, it is a fact that the "groggy state" is seen in amateurs he referred to nine deaths in the amateur ring in this country since the end of the late war (there were two in December, 1959)

Dr **J A Waycott** (Charterhouse School) admitted the undoubted benefits of boxing in developing muscular coordination and courage in adversity The sport is not as dangerous as some others But the "absolutely fundamental" difference, arising from the fact that the injuries in the ring are deliberate and intentional, distinguishes boxing from every other sport The chief target for such injuries is admittedly the brain No safeguards currently in use can possibly eliminate the fatal blow or detached retina Dr Waycott reminded his audience of the spectator's part The advocacy of cruel sports is a product not of reason but of the subconscious mind That is why it is so proof against arguments that appeal mainly to reason Natural displacements and sublimations are doubtless necessary, but it is vital to prohibit seriously objectionable outlets On balance the case against boxing, both medically and morally, is unassailable.

Dr **T A A Hunter** (Marlborough College) agreed that any sport whose primary purpose was the production of repeated head injuries must require very strong justification He wondered whether there was, in fact, evidence of such injuries resulting from schoolboy boxing

Dr **D E Dunnill** (Bexhill-on-Sea) condemned professional boxing but thought that amateur boxing should be retained because it teaches a boy the ability to defend himself

---

[2] Taylor, S, Fothergill, L *Lancet*, 1956, i, 1050

[1] Doggart, J H *A M.A Arch Ophthal* 1955, 54, 161

Dr R E SMITH (sometime medical officer, Rugby School) thought it quite wrong to compare amateur boxing with professional He stressed that many more injuries were sustained in other games and, anyway, what alternative was there if boxing were to go out?

Mr G A HODGES (director of physical education, Winchester College) said that after thirty years' experience he was convinced that boxing could be of great benefit educationally He condemned the bad features of much contemporary boxing and said that careful matching of contestants was essential This often involved leaving the best boxers out of a team in a match against another school and "unfortunately most schools won't accept this" He found that between 5 and 10% of boys wanted to box, and the feeble boy who suddenly found an unsuspected skill was often much helped in his outlook

Dr A W HENDERSON (St Edward's School, Oxford) thought that accidents occurred chiefly when amateur boxing was improperly supervised This, he felt, was an argument for more efficient supervision and control and not for the elimination of an admittedly dangerous sport

The Rev D L GRAHAM (Headmaster of Dean Close School) mentioned his long experience of boxing, which included a period in charge of the sport at Eton He had been a boxer himself for more than forty years Although boxing undoubtedly gave a boy a certain status there were other and better ways of acquiring this Dean Close has abandoned boxing because of its objectionable features, and replaced it by judo

Several other speakers referred to judo as the obvious alternative If properly publicised and taught, it easily catches the schoolboy imagination It is superior to boxing as a means of self-defence, and the rules are framed so as to avoid injury Any hurt occurring during its practice is accidental and not deliberate, as in boxing Fencing and single-sticks were also mentioned as possible alternatives

The meeting concluded with unanimous assent to the suggestion that further evidence should be obtained on the hazards of amateur boxing Dr CRITCHLEY said he would report this to the president of the Royal College of Physicians

Reviews of Books

Progress in Biochemistry Since 1949

FELIX HAUROWITZ, distinguished service professor, Indiana University Basle S Karger London and New York Interscience Publishers 1959 Pp 357 60*s*

IN a preface Dr Haurowitz says that one of his reasons for writing this book was to keep abreast of the state of biochemistry, and this volume is in fact the fifth in his series of self-imposed refresher courses He has certainly done his prospective readers a service by giving them this survey of progress in his subject during the past decade As is inevitable in a book of such wide scope, the chapters are somewhat uneven, but the best are very good and the others worth reading The application of thermodynamic arguments to biochemical problems and the general aspects of biological oxidations are particularly clearly expounded, and, as might be expected from the author's special interests, the chapters on proteins and their derivatives (which take up about a quarter of the book) are very full and fair Dr Haurowitz himself adheres to the idea of a template for polypeptide synthesis which includes preformed protein as well as ribonucleic acid Other chapters provide brief accounts of such varied topics as the biochemistry of lipids and carbohydrates (including amino-sugars and the several pathways of glucose catabolism), fat synthesis, hormones, antibiotics, and immunochemistry

The book can be highly recommended to those who have fallen behind in their biochemical reading, but it does assume a reasonable familiarity with the fundamentals of the subject References are plentiful and well chosen, and a glossary of over a hundred abbreviations affords both a sidelight on the popularity of such figures of speech among the professionals and enlightenment for amateurs not steeped in biochemical badinage

The Physiology and Treatment of Peptic Ulcer

Editor J GARROTT ALLEN, M D Chicago University of Chicago Press London Cambridge University Press 1959 Pp 236 56*s* 6*d*

HERE is an almost limitless subject, to judge from the volume of work, both observational and experimental, that has been pouring out over the years Nevertheless, and it is the achievement of the editor and his eleven noted contributors, condensation has been secured by intelligent sifting All the contributors have been under the influence of Dr Lester Dragstedt at some time in their career, and this monograph is their testimonial to him on his retirement The need to publish the work by the appointed day has imposed a praiseworthy economy, reflected in both conciseness and clarity, which will be fully appreciated by all readers There is an understandable bias towards physiology associated with the vagus nerve and vagotomy There is no cavil about the basic hypothesis on which experiment and argument are built, on the first page the dogma of pepsin is squarely stated by Dr Allen—the ulcer is a sequela of the digestive action of pepsin ergo, acidity is of paramount importance. And so to a consideration of the phases of gastric secretion and their mechanisms, and the various experimental pouches used for their study A chapter is devoted to the cephalic phase, another to the antral phase, and it is followed by one on its clinical importance The details of radiological diagnostic technique and interpretation are well set out in a chapter by Dr P C Hodges, treatment follows Gastric ulcer is dealt with in the two final chapters, with an epilogue by the master himself on "what I would do if I had an ulcer" We hope that he has not, but we are grateful for his massive contribution to the subject during a very active professional life, and not least for this tribute, a succinct, informative, and readable monograph, which his work has evoked

Clinical Chemical Pathology (2nd ed London Edward Arnold 1959 Pp 160 14*s*)—The new edition of this popular little book by Prof C H Gray illustrates the rapidity of change in this subject Test-meals are no longer considered in detail, but an account is now given of the van den Bergh reaction and its connection with non-conjugated and conjugated bilirubin, the value of the transaminase and other enzyme estimations in determining liver function, and diagnosis of cardiac infarction In the urine tests much, some may say too much, notice has been taken of the packaged tablet tests Chromatography has been introduced but very briefly The book continues to combine brevity with a remarkable completeness and clarity and will go on giving valuable service to one student generation after another

Complete Cookery Book for Diabetics (2nd ed London H K Lewis For the British Diabetic Association 1959 Pp 134 6*s*)—The second edition of this popular cookery book for diabetics by Iris Holland Rogers comes three years after the first It contains 33 new recipes, thus increasing further the great variety of meals offered in the exchange system More information is given about the use of sorbitol, and it is recommended that its caloric content should be assessed in diets for weight reduction A useful new table of equivalent quantities of different sweetening agents is also included Another new section deals with the bottling of fruit, and additional valuable advice is given about invalid diets This book is a bargain at 6*s*, and should be welcomed by any diabetics who feel that the scope of their meals is restricted

THE LANCET

LONDON 23 JANUARY 1960

Chemotherapy of Malignant Disease

The effect of the nitrogen-mustard group of drugs in the control of leukæmia and reticuloses led to their use in the treatment of malignant conditions, and other substances were tried Nitrogen mustard does destroy malignant tissue, but the dose that can be given is strictly limited by its toxic effect on blood-forming tissues—an effect which is made use of in the treatment of leukæmia Nevertheless, ordinary therapeutic doses of intravenous nitrogen mustard have been used for the palliation of inoperable tumours, especially carcinoma of the bronchus, and it has caused shrinking of lesions with considerable, though temporary, symptomatic relief Watson and Turner[1] used a combination of thiotepa (a mustard drug that can be given intramuscularly) and testosterone for the treatment of cancer of the breast, and they reported good results A different drug is 5-fluorouracil,[2] an antimetabolite with an action similar to that of the drugs used in the control of acute leukæmias, and still another type, an antibiotic, actinomycin D, has been used in Hodgkin's disease.[3]

It was clear that better results might be obtained if the concentration of the drug actually reaching the tumour could be increased A method of doing this was to isolate the circulation of the tumour area from the general circulation and then perfuse the isolated area with a really large dose of preferably a short-acting drug such as nitrogen mustard We reviewed the preliminary results obtained with this technique some months ago[4] Creech and his colleagues now report further results[5] with what they describe as "regional" and "total-body" perfusion In regional perfusion the artery and vein supplying the part are occluded proximally, cannulated in a distal direction, and connected to an extracorporeal circuit consisting of arterial and venous pumps and a bubble oxygenator If the tumour area is in the limbs, tourniquets are used to isolate more effectively the perfused area Perfusion of the lungs had been managed by using two extracorporeal circuits, one for the heart and lungs and one for the systemic circulation In total-body perfusion, catheters are passed into the thoracic aorta and the inferior vena cava by way of the common femoral artery and vein Before the perfusion is begun, as much marrow as possible is removed from the iliac crests and sternum, kept at 4°C, and returned to the patient by the intravenous route after the effect of the perfused nitrogen mustard or other drug has passed off The chemotherapeutic agents used were nitrogen mustard, phenylalanine nitrogen mustard, and triethylenethiophosphoramide; a few patients were given 5-fluorouracil or actinomycin D Recommended doses with nitrogen mustard vary from 0 6 mg per kg body-weight for upper-extremity perfusion to 1 0 mg per kg for pelvis perfusions[6] Krementz et al[7] describe more fully the treatment these workers give for tumours of the extremities

Creech et al now give results obtained with 145 patients treated by perfusion methods, these included 40 with malignant melanomas, 28 with sarcomas, 72 with carcinomas, and 5 with glial tumours The proportion classed as "quiescent" after treatment was 46%, in 22% there was recurrence after initial response and in 25% there was no response, only 2 patients died from the direct effects of chemotherapy Some interesting conclusions are drawn from their experience Although regional perfusion methods produce concentrations of the chemotherapeutic agent 15–20 times as high as with systemic administration, none of the drugs tested "cured" the tumour Nor is there evidence that any particular drug is more useful for the treatment of a particular tumour, sometimes an individual tumour will respond better to one drug than another, but this may not be true in the next patient with a similar tumour Creech et al are trying to devise a "sensitivity test", but so far it is very crude Depression of blood formation, especially leucopenia, is a complication that has often to be reckoned with when large doses of these toxic drugs are used It is least troublesome in regional limb perfusions with good isolation when a short-acting drug such as nitrogen mustard is used, it is more serious when effective isolation is less feasible, as in pelvic perfusions, or when a longer-acting drug such as thiotepa is used, and it is most serious in total-body perfusions In most of the 145 patients the depression was not serious, but in 19% of patients the white-cell count fell below 1000 per c.mm , fortunately, recovery from these severe changes can often be encouraged by transfusions of fresh blood and administration of steroids and antibiotics

On the whole the best results have been obtained in the treatment of metastatic melanoma in the limbs, and better results have followed treatment of carcinoma of the genito-urinary tract, lung, and breast than elsewhere "While in no instance has an advanced lesion in these areas been arrested, significant palliation has been afforded in some cases and in others a non-resectable lesion has been converted to a resectable one" Relief of pain has been observed in almost every case These isolation-perfusion techniques can only be carried out in hospitals equipped to provide extracorporeal circulation But the systemic use of these chemotherapeutic substances, even if less effective, can be carried out anywhere and some relief given to the patient Raphael and Reilly,[8] for example, gave standard nitrogen mustard to 56 patients with inoperable carcinoma of the bronchus and obtained significant palliation in 15

[8] Raphael, M, Reilly, C N *Dis Chest*, 1954, 25, 215

On p 206 of this issue, Mr GORDON JACK and his colleagues record results with the nitrogen-mustard drug tretamine (T E M, triethylenemelamine) in 43 patients with inoperable lung cancer 30 patients showed subjective improvement and in 10 " marked to complete " regression of the tumour ensued, the X-ray appearances returning to normal or near-normal in 4 of them They therefore recommend that tretamine, in a single dose of 20–30 mg (0 35 mg per kg) given intravenously, should be tried in patients with inoperable carcinoma of the lung There is now enough evidence for giving one of the nitrogen-mustard drugs to such patients, but not everyone will agree with the choice of tretamine Earlier indications[9] were that tretamine was one of the most toxic and one of the less reliable of the nitrogen-mustard drugs that had been given clinical trial[9], and CREECH et al do not recommend its use Mr JACK and his colleagues had much trouble with hæmopoietic depression For the palliative treatment of malignant disease with nitrogen-mustard drugs, there still seems much to be said in favour of the less toxic members of the group, nitrogen mustard itself in the bis form (mustine) or the tris form (' Trillekamin '), or, if intravenous injections have to be avoided, the now well-tried thiotepa

Stereotaxic Operations on the Brain

JUST over fifty years ago HORSLEY and CLARKE[10] introduced the principle of locating points in the brain by reference to a three-dimensional frame applied to the head Originally the points of reference connecting the skull to the frame were the external meati and the infra-orbital margins, and these remain the basis of most alignments For many years work was confined to animals, but SPIEGEL et al[11] applied the method to the human brain and in the past decade an intensive attack has been made on the technical problems, which are considerable The original frames outlined the edges of a box, but a popular adaptation described by LEKSELL[12] used the principle of a movable arc with an electrode carrier that could slide along the arc, which represented part of the circumference of a circle An electrode or cannula of a length equal to the radius would terminate always at the centre of the circle, no matter where the point of entry was through the skull The instrumental accuracy can be brought to a high level The machine should be rigid but light, should have clearly defined points and lines for radiological identification, should be aligned with accuracy to the central ray of an X-ray tube, and should be reapplicable to the head in exactly the same position on separate occasions This is achieved most simply by leaving screws in the skull after the setting of all movable parts of the frame in relation to the screws has been recorded Unfortunately, accuracy does not depend solely on the design of the instrument Maps of different human brains have shown that the dimensions of internal structure vary independently of one another, much as do the features of the human face Even the most accurate averaged map cannot apply entirely to an individual brain, but the margin of error can be reduced by the use of proportions and of ventricular landmarks close to the target[13–16]

In treatment it is difficult to produce a large cerebral lesion that is accurate in size, shape, and centre Leucotomes,[17] diathermy, and direct current destruction have been used, and also the injection of sclerosing solutions[18] with or without prior separation of the local tissues Repeated small lesions require repeated insertions of an electrode, though a movable central stilette has been pushed in varying directions from the tip of a cannula in order to reduce the number of punctures through the rest of the brain

The purposes for which these methods have been employed have been restricted so far by the limitations of our knowledge of anatomy, physiology, and pathology RIECHERT[19] has summarised the indications, of which the commonest at present is parkinsonism Destructive lesions in the globus pallidus, ansa lenticularis, and nucleus ventralis lateralis thalami have produced better results in this disease than any other surgical procedure —a fact which has given great impetus to the development of stereotaxic methods The results have also been encouraging in hemiballismus, Huntington's chorea, athetosis, and other dystonias[20–23] Pain relief is particularly difficult to assess Attempts have been made to destroy the nucleus ventralis posterior and the nucleus centrum medianum thalami, apparently with some success[24] The intractable " thalamic " pain associated with vascular lesions is said to be relieved by destruction of nucleus centrum medianum, which may receive fine fibres running through the reticular formation, probably by multisynaptic paths[25] Epilepsy due to bilateral or central foci can be tackled most suitably by stereotaxic methods aimed at deep structures—either nuclei or tracts—to break pathways concerned in the spread of seizures targets have included the internal medullary lamina of the thalamus,[26] the fornix,[27] and the temporal isthmus[28] The pituitary gland can be entered by such means, but in view of the proximity of the optic nerves and chiasma, open operation will probably remain preferable in most cases In the treatment of schizophrenia the results of destruction of the nucleus dorsalis medialis are roughly comparable with those of the " standard " prefrontal leucotomy

Every new piece of information about the results of stimulation and of temporary or permanent paralysis of each known structure in the brain will enhance the accuracy of stereotaxic methods The dynamic view of brain function lays greater emphasis than ever on tracts of internal communication We hope that by means of research advantage will be taken of the technical methods now within our reach

Bone-marrow Preservation

Bone-marrow "grafts" or transfusions are being increasingly used[1] Such grafts consist of marrow cells obtained by aspiration from the sternum or the iliac bones They have so far been used in three conditions in aplastic anæmia of unknown origin, or known to be due to accidental exposure to radiation, in acute leukæmia following whole-body irradiation designed to destroy the abnormal marrow and to suppress immune reactions, and after treatment of widespread malignant disease by large doses of nitrogen-mustard drugs The possible sources of bone-marrow and the various methods of using it have been reviewed by Wilson[2]

Bone-marrow can be autologous (from the same patient) isologous (from an identical twin), or homologous (from another person, usually selected because his blood-groups are as similar as possible to those of the recipient) Autologous marrow is used in two ways In the treatment of malignant disease by nitrogen mustard, marrow can be withdrawn, kept at 4°C for one or two hours, and then reinfused, since the action of the mustard drug is over in about an hour, with this method no elaborate storage techniques are required The other use of autologous marrow is to draw off healthy marrow from a patient with leukæmia at a time when he is in remission, spontaneous or induced by drugs, this marrow is stored until a relapse occurs, and the patient is treated by total-body irradiation of 570–600 r followed by intravenous infusion of this stored normal marrow This method has been applied by McGovern et al[3] in three cases of acute lymphoblastic leukæmia, one patient died nine days after irradiation with the leukæmia still present, one died after twenty-three days and no postmortem evidence of either leukæmia or repopulation of the marrow was found, in the third case the marrow reverted to normal within seventeen days and there was complete hæmatological and clinical remission

Homologous marrow can also be used with or without storage, though storage is now more usual Much more marrow is required than for diagnostic taps, and Wilson considers that the sternum and the posterior ilium are the sites most likely to give a satisfactory amount of cells Bierman and Kelly[4] found that a single puncture of the posterior ilium yielded 10–20 ml of material with minimal admixture of blood Wilson prefers multiple aspirations with the donor under general anæsthesia, using both sternum and posterior ilium he obtained yields of from 3×10^9 to 16×10^9 cells The cells obtained by these aspirations are usually received into one of the balanced salt solutions, such as Hank's solution,[5] to which an anticoagulant has been added If the marrow is to be administered without storage, sequestrene (ethylene di-amino-tetra-acetate) 1–2 mg per 20 ml of solution is added, but if the marrow is to be frozen for storage, heparin (which must be free from phenol) 10 mg per 100 ml is preferable

For storage, all workers recommend freezing in the presence of glycerin and keeping at −79°C, with reconstitution just before the marrow is to be used Storage at −20°C does not seem to be satisfactory, Mollison et al[6] found that when red blood-cells were stored at this temperature a large proportion were lost by hæmolysis during the recovery process, and the same may apply to marrow cells Cooling to −79°C (the temperature of a mixture of solid carbon dioxide and industrial spirit) a suspension of cells in a glycerin solution dates from the demonstration by Polge et al[7] ten years ago that fowl semen could be preserved by this method and the application by Audrey Smith[8] of this technique to the preservation of red blood-cells

Newton et al[9] at the Westminster Hospital suspend the marrow in a mixture of Hank's solution, inactivated human AB serum, 'Bacto' yeast extract, glucose, penicillin, streptomycin, and heparin, then they free the mixture from unwanted tissue particles by passing it through suitable stainless-steel filters of various grades The filtered suspension is mixed with glycerin to give a final glycerin concentration of 15% v/v After equilibration for ten minutes, 7 ml portions of the mixture are sealed into glass ampoules "and cooled at 1°C per minute to −15°C and thereafter at a rate not exceeding 10°C per minute to −79°C" The necessity for differential cooling, with a relatively slow rate down to −15°C and then a much accelerated rate below −15°C, is a serious technical snag, and special apparatus has been designed to overcome it Pegg and Trotman,[10] of the Westminster team, have designed an electrical apparatus that will take nineteen of the 7 ml ampoules at one time and cool them in the desired manner, others have used commercially assembled apparatus The frozen marrow is reconstituted by rapid thawing in a water-bath at 38°C, and then a half-volume of 35% glucose in balanced saline solution is added and well mixed, two minutes later an equal volume of balanced saline is added, followed by a further volume of saline in another two minutes This produces a cell-suspension in 2 5% glycerin and slightly hypertonic glucose-saline solution, and such a mixture can safely be given intravenously In the U S A somewhat more elaborate techniques making use of multiple plastic packs have been described[11] These disposable plastic packs are convenient and they ensure sterility, they are in common use for blood-transfusion work in the U S A, but in this country they are expensive

Marrow from living adult donors has been most used, but this is clearly no light undertaking if a general anæsthetic has to be given to enable enough marrow to be obtained without much pain and discomfort, marrow donation is much more incommoding than blood donation Other sources have been explored Ferrebee et al [11] obtained considerable quantities of marrow from the ribs and vertebræ of adult cadavers, the subjects had died from non-septic and non-malignant conditions, and the marrow was collected if possible within two hours after death Fœtal tissue has the advantage of "immunological immaturity" and is therefore less likely to provoke immune reactions in the host, **Kay** and **Constandoukalis** [12] have discussed the advantages and limitations of this source

All this work tells us that there will possibly be increasing scope for the use of marrow grafts in the management of some blood diseases and widespread malignant conditions, but its value for the treatment of acute leukæmia is still doubtful Direct transfer of donor marrow or autologous marrow is relatively simple to arrange, but proper storage under conditions that will ensure a viable cell-suspension on reconstitution is much more difficult and needs special apparatus not normally found in hospital laboratories It might, however, be worth while to equip at least a few hospitals to undertake this work

Annotations

TREATMENT OF TUBERCULOUS MENINGITIS

Tuberculous meningitis has a high mortality and incidence of relapse and of irreparable sequelæ unless it is vigorously treated Whether intrathecal therapy is essential is undecided, for no controlled trial has been reported The need for such a trial is clear Smith and her colleagues [13] have stressed that the amnesia of the active phase of the disease is profound, but this does not preclude psychological trauma resulting from repeated lumbar punctures, which moreover entail a risk of secondary infection and damage to the cord besides much time and labour Lorber [14] reported that administration of isoniazid enabled the course of intrathecal streptomycin to be shortened, but he noted that after withdrawal of streptomycin the cerebrospinal-fluid (C S F) picture might deteriorate during isoniazid therapy Smith et al [13] could not determine the value of isoniazid because its introduction coincided with other changes in therapeutic regimen Torres-Gost [15] reported impressive results with intramuscular streptomycin and oral and intrathecal isoniazid, but whether the intrathecal therapy had any value cannot be determined Estimations of isoniazid in the C S F after oral administration suggest that it diffuses freely [16] The Scottish Joint Committee trial [17] was of three different schedules, but each included intrathecal streptomycin Two new reports [18 19] add a little to our knowledge Wright [18] compared the results of treatment with intramuscular and intrathecal streptomycin with those obtained from intramuscular streptomycin, together, in some cases, with isoniazid and *p*-aminosalicylic acid (P A S) With the latter regimen the results were good, the survival-rate being 83 3%, but would they have been better if streptomycin had been given intrathecally as well? Fyfe [19] compared the results obtained by, on the one hand, intrathecal injections of streptomycin and, on *the other hand*, no intrathecal therapy The intrathecal course was short by the standards of many centres, and other drugs, such as steroids and P A S, were given to some patients in both groups, which were small Fyfe is probably wise not to draw firm conclusions

Possibly compromise schedules have delayed definition of the best Some may feel that the onus of proof now lies on those who advocate a course of intrathecal streptomycin therapy, but, since intrathecal therapy in the dose range used today seems unlikely to exert an unfavourable influence on recovery, a controlled trial, based on sequential analysis, could best be done by a centre advocating its discontinuance In the treatment of other types of bacterial meningitis—particularly pneumococcal meningitis—where controversy persists about the use of intrathecal penicillin, similar trials are also overdue

GIANT-CELL PNEUMONIA

Giant-cell pneumonia is an interstitial pneumonitis which has so far been observed only in children Microscopic examination of affected lung shows multinuclear giant cells with intranuclear and intracytoplasmic inclusion bodies, aggregations of mononuclear cells, proliferation of alveolar lining cells, and squamous metaplasia of bronchial epithelium [1–9], occasional giant cells are found in organs other than the lungs Diagnosis is made histologically, as there are no distinctive clinical features Although this condition was described by Hecht [1] as long ago as 1910 its cause has remained in doubt Circumstantial evidence has incriminated canine distemper virus and measles virus, but direct evidence has been lacking Now, however, studies by Enders and his associates [10 11] suggest that a final verdict on ætiology may shortly be delivered

These workers investigated 3 cases of fatal giant-cell pneumonia in young children under treatment for mucoviscidosis, leukæmia, and Letterer-Siwe disease [10] All 3 had been exposed to measles shortly before the onset of the final illness, but no rash had developed Post mortem the nature of the pneumonia was established by histological examination, the presence of the chronic conditions previously diagnosed was confirmed, and specimens were obtained for virus studies Agents inducing the formation of "syncytia" or "giant cells" were isolated in tissue-cultures from material obtained from the bronchial tree in the 1st case, from lung in the 2nd, and from lung and liver in the 3rd In each case the agents were recovered only in human renal cells, although material from 2 cases was repeatedly tested in human amnion cells Cytopathic changes, first observed five to fifteen days after inoculation, were indistinguishable from those induced by measles virus The agent also induced changes identical with those induced by measles virus in monkey renal cells, HeLa cells, and Detroit-6 cells, and could be adapted to human amnion cells by methods appropriate for measles virus Like measles virus the agent multiplied relatively slowly in human renal cell and amnion cell cultures Three cynomolgus monkeys were inoculated intravenously with fluids infected with virus from one of the cases (one was also inoculated intranasally and two also intramuscularly) By the twenty-sixth day complement-fixing antibodies reacting with measles virus, and antibodies that inhibited the cytopathic action of measles virus, had appeared Although virus was recovered from the blood of two of the monkeys, no exanthem appeared, but in the experience of Enders et al an exanthem appears in only about half the susceptible cynomolgus monkeys inoculated with measles virus

Giant-cell pneumonia virus and measles virus were used as antigens in neutralising and complement-fixation tests with acute and convalescent sera from a patient with measles, a monkey infected with the Edmonston strain of measles virus, and a monkey infected with giant-cell-pneumonia virus The differences in the virus-neutralising and complement-fixing antibody titres of the convalescent-phase sera were so small as to suggest that the giant-cell-pneumonia virus and measles virus were not only of similar, but of identical, antigenic composition

As it has been claimed that the virus of canine distemper may induce the histological changes of giant-cell pneumonia,[-6] and that distemper and measles viruses are antigenically related,[12 13] Enders et al tested the capacity of canine anti-distemper serum to neutralise the cytopathic effect of two of the giant-cell pneumonia viruses, and to fix complement in the presence of these agents No antibodies were detected in the dilutions of the serum tested Cabasso et al[14] also failed to obtain convincing evidence of an antigenic relationship between distemper and measles viruses

Enders et al subsequently investigated 4 leukæmic children in whom interstitial pneumonia developed shortly after an overt attack of measles[11] Giant-cell pneumonia was presumptively diagnosed 2 of the children died, and the diagnosis was confirmed post mortem Measles virus was isolated from throat washings and from the lungs of these 2 patients, and from throat washings of 1 of the patients who recovered (in the remaining case throat washings were not examined) Virus was not detected in the blood of any of these patients, but all had received γ-globulin Measles virus persisted remarkably in the oropharynx usually it cannot be isolated after the early phase of the exanthem, yet in the 2 fatal cases it was isolated one month and three weeks after the appearance of the rash, and in 1 of the other cases it was isolated ten days after the onset of prodromal measles Feeble antibody production was another noteworthy feature normally, moderate to high concentrations of complement-fixing and neutralising antibodies are rapidly attained, but in the 2 patients who recovered antibody production was subnormal, and in the 2 fatal cases it was virtually absent As none of the patients had agammaglobulinæmia or had received drugs likely to interfere with antibody production, the depressed response of the defence mechanism may have been due to the coexistence of chronic debilitating disease—a hypothesis that might also account for the puzzling absence of a rash in the 3 cases first studied Enders et al , however, do not regard this explanation as satisfactory, for they have observed cases of leukæmia in which measles has run a normal course Problems, therefore, remain to be solved, but at least it now seems certain that measles virus is the cause of some cases of giant-cell pneumonia whether it is the cause of all cases remains to be seen

BODY STRUCTURE AND THE ADRENAL CORTEX

In a new classification of body build which J M Tanner and his colleagues[1] are developing, skeletal frame size, skeletal width, muscle width, and fat width are measured The measurements are made in soft-tissue radiographs, the muscle width being calculated by subtracting the width of the long bones and the two fat measurements from the overall diameter of the limb Tanner et al related these and other measurements in 101 healthy male medical students to the daily urinary output of 17-ketosteroids (17-K S) and 17-ketogenic steroids (17-K G S) They showed that the excretion of 17-K S is significantly related to body-weight and to muscularity This relation of androgen excretion to muscular development has already been observed in physiological conditions, such as adolescence and old age, and in disease states, such as the adrenogenital syndrome The mechanism underlying this association is unknown, and Tanner suggests that the androgens " enter in some way into muscle metabolism " There are, of course, several other possibilities, and indeed there may be no causal association between these two observations, statistically significant though their relationship has now been shown to be Tanner et al found no relation between 17-K S excretion and the size of the penis, and no relation between 17-K S excretion and the biacromial and biliac diameters, although these measurements are accepted as an index of androgyny The only male character which correlated positively with the 17-K S output was the degree of hirsuties Anthropometrists should seek to relate their structural measurements to function, just as the somatotypists are looking for relationships between body shape and behaviour[2], and it would have been interesting to have learnt whether there was any correlation between the libido of these young men, judged by the frequency of seminal emissions, and their androgen output

Tanner et al conclude that the excretion of 17-K G S is positively related to the width and length of the limb bones They point out that bone width, measured by their method, refers to width of the medullary cavity, the thickness of the cortex being related more to the overlying muscle than to bone size itself They speculate whether the corticosteroids may thus have some part in maintaining the contents of the medulla of the long bones This is an interesting suggestion, but it is even further removed from proof than the idea that the androgens are concerned with the metabolism of muscle

Resistance to the development of tuberculosis has been shown by Palmer et al[3] to be lower in tuberculin-positive men who are tall and light than in those that are heavy and short, and they wonder whether the subjects susceptible to tuberculosis have wide and long bones and a high ketogenic output, since corticosteroids are known to lower resistance to infection Such speculations are healthy and to be welcomed, provided that they are not

confused with established fact It is by combination of fact and speculation that much scientific progress has been achieved Tanner and his colleagues have provided themselves and other workers with a target for tomorrow

CHOLINESTERASE ACTIVITY IN THE CEREBROSPINAL FLUID

THE basal ganglia have a considerably higher content of acetylcholine-splitting enzymes than the rest of the central nervous system [1] Very active acetylcholine synthesis has also been demonstrated in the caudate nucleus of dogs,[2] indicating a lively local metabolism of this substance Here, as elsewhere in the cerebral grey matter, the enzyme is predominantly of the "true" ("specific" or aceto-cholinesterase) variety,[3] probably identical with that found in erythrocytes

Unilateral intra-carotid injection of an anticholinesterase drug, diisopropylfluorophosphate (D F P), produces in rabbits an involuntary circling behaviour [4], the associated assymmetrical inhibition of cholinesterase in the brain is most severe in the caudate nucleus and the frontal cortex [5] Administration of D F P to subjects with schizophrenia was followed in some cases by "activation" of the psychosis, or the reappearance in chronic cases of the florid symptoms which had characterised the onset of the illness, these patients showed fewer electroencephalographic changes, and had less severe gastrointestinal and cardiovascular symptoms, than manic-depressive or healthy people who received the same drug [6]

The cholinesterase activity of the cerebrospinal fluid is very low, and its physiological significance uncertain, but the assumption that its lèvel reflects the enzymatic activity of the brain has led to investigations in neurological and mental disorders High true-cholinesterase activity was found in the cerebrospinal fluid in tumours of the central nervous system and in tuberculous meningitis, low values in poliomyelitis, general paresis, and epilepsy [2] Jefferson [7] found normal cholinesterase activity in the cerebrospinal fluid of fourteen patients with disseminated sclerosis, and he concluded that long-continued depression of pseudo-cholinesterase ("non-specific" or butyrocholinesterase) is unlikely to play a major part in the pathogenesis of this condition This conclusion followed the observation that anticholinesterase agents can provoke demyelination in man [8] Bernsohn et al [9] have reported high true-cholinesterase activity in myasthenia gravis, in the Guillain-Barré syndrome there was a considerable increase of ali-esterase activity, probably secondary to the high albumin content of the cerebrospinal fluid

In a group of patients with schizophrenia (in most cases chronic) Hungarian workers[10] have found much-reduced true-cholinesterase activity in the cerebrospinal fluid, the values increasing in parallel with clinical improvement after electroconvulsive treatment Other, presumably also long-stay, patients with general paresis, epilepsy, or mental defect showed only moderate inhibition of cholinesterase activity in their cerebrospinal fluid, while three acute cases (two of neurasthenia and one of paranoid state) had normal values The estimations were carried out by a titrimetric method—not with the customary, and more reliable, manometric method—and the nutritional state of these patients is not described. These findings are at variance with those of Mutrux and Glasson,[11] who reported that true cholinesterase, pseudo-cholinesterase, and ali-esterase were present in various amounts and combinations in the cerebrospinal fluid of a hundred psychiatric patients but could find no pattern characteristic of diagnostic groups, including schizophrenia

THE DISTURBED CHILD GROWS UP

THOUGH child-guidance clinics are increasing, their number is still insufficient, and many are understaffed Somewhere between 5 and 12% of the school population require referral to a clinic,[12] and Dr Mildred Creak [13] has suggested that the clinics, overworked and with staff often inexperienced and in academic isolation, may fail to meet this challenge

Disturbance in the individual child can now be more clearly delineated [14], but diagnostic groupings are still unestablished, and accordingly some psychiatrists have wished to abandon diagnosis altogether—a proposal which Kanner [15] has rightly criticised as retrograde It is clearly important to find out what happens to these children when they grow up, and the studies of O'Neal and Robins,[16–18] though still incomplete, help to fill this gap in our knowledge

Their follow-up of some 500 children seen at a psychiatric clinic in St Louis thirty years ago, compared with a matched control group, showed an increased incidence of adult psychiatric disorders, the excess being largely accounted for by schizophrenia and sociopathic personality Neurotic illnesses differed little between the two groups Adults diagnosed as having sociopathic personalities had mostly been delinquents in childhood, while many of those who became schizophrenic had presented problems of aggressive antisocial behaviour Those patients who were psychiatrically well as adults came chiefly from the group of children with neurotic problems Of the delinquent children, 38% had not been arrested as adults, but the rate, severity, and chronicity of adult crime in the delinquent group was nevertheless high The incidence of violent deaths among the males was striking 4% had been killed, and no less than half of these had been shot by the police Comparing a group of aggressive antisocial children who became schizophrenic with a similar group of children who in adult life were without psychiatric disease, O'Neal and Robins found that the preschizophrenics had had more symptoms of all kinds, and that more areas of function had been disturbed

Antisocial behaviour in the preschizophrenic child has been previously reported by Morris et al [19] Clearly there may be considerable differences between the clientele of an American child-guidance clinic thirty years ago and a British clinic today, but the evidence so far suggests that it is the antisocial child rather than the neurotic who is most in need of help

RADIATION EXPOSURE: CREDIT AND DEBIT *

T C CARTER
O B.E , M.A , Ph D Cantab , D Sc. Edin
MEDICAL RESEARCH COUNCIL'S RADIOBIOLOGICAL RESEARCH UNIT, HARWELL, BERKSHIRE

THE original aim of radiation protection measures was the prevention of radiation-induced somatic damage in radiological workers, it was supposed that damage was induced only if the exposure exceeded some threshold, and the functions of the protection authority were to assess the scientific evidence on the position of this threshold and ensure that it was not crossed. Today a quite different problem has to be faced, since we now believe that there is no dose threshold for the induction of genetic damage, and that there may be no threshold for the induction of some types of somatic damage.

This new concept of the nature of radiation hazards calls for a new approach to the problems of protection. The only ethically admissible approach appears to be to assess, as accurately as present knowledge permits, the good and the harm that would be done by each exposure to ionising radiation, and on this assessment to base the decision whether to make the exposure or not. The credit side of this balance sheet should be drawn up by those advocating the exposure, the debit side by the protection authority, the decision whether or not to proceed with the proposal, which is a matter not of science but of national policy, should not necessarily be taken by scientists alone. This procedure is clearly an ideal to be aimed at, and it would be difficult to apply it in all cases today. One of its difficulties lies in that fact that the benefits obtained from most uses of ionising radiation, especially its medical applications, are immediate and their causal connexion with the exposure is obvious, whereas the damage, especially the genetic damage, may not become apparent for many years and its connexion with the exposure is usually undemonstrable, in other words, the damage constitutes a long-term debt to be paid eventually by somebody other than the borrower. Another and more immediate difficulty is that of estimating the magnitude of the somatic and genetic debts.

Some attempts have in fact been made to draw up balance sheets for particular uses of ionising radiation. One example is to be found in the interim report of the Committee on Radiological Hazards to Patients,[1] which dealt with mass-miniature radiography of the chest. Referring to the year 1957, the committee reported

Credit	
Cases found	
Pulmonary tuberculosis	17,835
Cardiac abnormalities	12,000
Pneumoconiosis	9400
Lung cancer	2362
Debit	
Cases possibly induced but yet to appear	
Leukæmia	20 (maximum)

The debit side of this balance sheet is incomplete, in that only one component of the somatic debt was estimated, and the genetic debt is not mentioned. How can it be calculated?

To estimate the total genetic debt arising from a given exposure it is necessary to know, for every deleterious condition, (*a*) the genetic mechanisms by which it is maintained in the population, and in particular how its incidence is related to the mutation-rate of genes concerned, and (*b*) how the mutation-rate is related to radiation exposure. The genetic mechanisms by which many conditions are maintained are unknown, they include numerically important conditions such as hæmolytic disease of the newborn, diabetes mellitus, manic depressive psychoses, schizophrenia, exophthalmic goitre, pernicious anæmia, fibrocystic disease of the pancreas, most deaf-mutism, and the majority of congenital anomalies.[2] For these it is therefore impossible at present to assess the genetic debt created by any given exposure. This may be less important than it appears at first sight, because there is reason to suspect that some of them, at least, may be maintained by causes other than mutation pressure, and their incidence may therefore be affected little, if at all, by changes in the mutation-rate, where this applies the genetic debt created by radiation would be small, even though the condition itself is relatively common.

On the other hand, there are many conditions which there is good reason to believe are the expressions of single mutant genes maintained in the population by mutation pressure, their incidence in a population in genetic equilibrium will be directly proportional to the mutation-rate, and in respect of them any radiation exposure will create a genetic debt. The incidence of defects of this type in the population of Northern Ireland has been reported by Stevenson.[2] He listed 142 such conditions, and reported their incidence at birth and in the surviving population. Many had relatively unimportant effects on the individual—e g , alopecia areata, spasm of the eyelid, camptodactyly, polydactyly, Garber's toe anomaly, such minor defects totalled 23,132 per million births and had a similar incidence in the surviving population. Many others, however, had relatively serious effects on the individual. they included achondroplasia, ectrodactyly, aniridia, congenital cataracts, infantile glaucoma, retinoblastoma, some deaf-mutism, megacolon, amaurotic idiocy, ichthyosis congenita, hæmophilia, and sex-linked muscular dystrophy, such major defects totalled 11,727 per million births, with a smaller incidence in the surviving population. These incidences may be taken as representative of the British population.

The relationship between the human mutation-rate and radiation exposure is much less certainly known, it is usually expressed in terms of the mutation-rate-doubling dose—i e , the genetically effective radiation dose that would induce as much mutation per generation as arises spontaneously. The United Nations Scientific Committee[3] concluded that the doubling dose for man probably lies somewhere in the range between 10 and 100 rem. For acute exposure of spermatogonia in adult male mice the doubling dose is about 30 rem[4] and for chronic exposure about 95 rem.[5] In what follows it will be assumed that the doubling dose for man is 100 rem, and it seems probable that any error introduced thereby will be in the direction of optimism.

We can now estimate the component of the genetic debt due to single mutation-maintained genes incurred through any given exposure of the British population We have the following data

---

* Based on a paper presented, by invitation, to the International Commission on Radiological Protection, July 24, 1959

[1] Interim Report of the Committee on Radiological Hazards to Patients London, 1959

[2] Stevenson, A.C. *Radiation Research*, 1959, suppl 1, 306

[3] Report of the United Nations Scientific Committee on the Effects of Atomic Radiation, New York, 1958

[4] Russell, W L., Kelly, E M *Science*, 1958, 127, 1062

[5] Carter, T C., Lyon, M. F , Phillips, R. J S *Nature, Lond* 1958, 182, 409

(i) Natural background radiation[6]	0 1 rem/per yr
Mean generation period [6]	30 yr
Accumulated background dose per generation	3 rem
Mutation-rate-doubling dose (assumed)	100 rem
Fraction of spontaneous mutation that is induced by background radiation	3/100
(ii) Incidence of single-gene defects maintained by mutation pressure	
Minor defects	23,132 per 10^6 births
Major defects	11,727 per 10^6 births
Births in the U K (1958)[7]	851,466 per annum
Number of single-gene mutation-maintained defects occurring annually in the U K	
Minor defects	23,132 × 0 851,466 = 19,696 cases
Major defects	11,727 × 0 851,466 = 9,985 cases
Number occurring annually in the U K as a result of a continuing exposure to natural background radiation at an annual rate of 0 1 rem	
Minor defects	19,696 × 3/100 = 591 cases
Major defects	9,985 × 3/100 = 299 cases
Genetic debt created by a dose of 1 rem to the U K. population, howsoever distributed in time	
Minor defects	591/0 1 = 5910 cases
Major defects	299/0 1 = 2990 cases

These estimates, of course, are no more accurate than the assumptions on which they are based, it is more realistic to round them off to 6000 and 3000 respectively

Before they can be used to estimate the genetic debt due to mass miniature radiography, it is necessary to know the genetically effective radiation dose due to this procedure It was not calculated in the interim report,[1] but an upper limit can be estimated There were 4,770,927 examinations and the mean gonad dose per examination was of the order of 0 00012 rem for females and 0 00010 rem for males In the British population there are about 22 million people under the mean age of reproduction, 30 [7] If all the people examined had been drawn from this section of the population and if males and females had been examined with equal frequency, the average genetically effective dose would have been 0 00011 × 4 77/22 = 0 000024 rem As some of those examined were over the age of reproduction, the effective mean dose must have been less than this It follows that the component of the genetic debt due to single mutation-maintained genes is estimated to be less than

Minor defects	6000 × 0 000024 = 0 14 cases
Major defects	3000 × 0 000024 = 0 07 cases

It is clear that this debt is very small compared with the immediate benefits obtained

For comparison we may also estimate the corresponding component of the debt created if one of the recent recommendations of the International Commission on Radiological Protection [8] were to be adopted in Great Britain—namely, that referring to exposure of the population at large The exposure envisaged is in addition to all medical exposures (patient and staff), industrial exposures, exposures in atomic-energy installations, and exposures to persons living near them It therefore includes only exposure due to contamination of the environment from radioactive waste disposal, reactor accidents, nuclear weapon tests, and minor sources, such as luminous watches, X-ray shoe-fitting machines, television sets, and so on For these the I C R P suggests a permissible genetically effective dose of up to 2 rem per 30 years The genetic debt of single-gene mutation-maintained defects that would be created by this exposure is estimated to be

Minor defects	6000 × 2/30 = 400 cases per year
Major defects	3000 × 2/30 = 200 cases per year

It is difficult to see why the I C R P has chosen such a high figure According to the Medical Research Council,[6] the genetically effective dose from all these sources was at a rate of less than about 0 07 rem per generation in 1956, and it can hardly have been doubled since that date the new I C R P recommendation is 30 times as high If occupational exposures are included, the M R C estimate of the 1956 rate of exposure was about 0 1 rem per generation the corresponding new I C R P recommendation is higher by a factor of 35

We may also estimate the corresponding component of the genetic debt due to diagnostic radiology In Great Britain the genetically effective dose from this source is at least 22% of that due to natural background radiation—i e, it is at least 0 022 rem per year,[6] but not more than 3 rem per generation, or 0 1 rem per year [1] The corresponding components of the genetic debt are estimated at

	Cases per year	
	Dose 0 022 rem/per yr	*Dose 0 1 rem/per yr*
Minor defects	132	600
Major defects	66	300

These figures are large enough to justify considerable effort and expense to reduce the dose to the patient, especially in the few procedures which contribute the larger part of the genetically effective dose (examination of the hip and femur, lumbar spine, abdomen, pyelography, pelvimetry, &c)

It may be asked why such a genetic debt has not been observed, if it exists, since most of the major defects are due to dominant genes which will begin to express their effects as soon as they enter the population But most of these genes persist in the population for several generations before dying out, and diagnostic radiology has been used for only two generations, therefore many of the induced mutant genes, even those induced by the earliest radiologists, have not yet finished expressing their effects The full rise in radiation-induced major defects is therefore yet to come, and not until it does will the number of cases per year equal the annual increment to the genetic debt For the rise to be demonstrable with statistical significance it must exceed twice the standard error of the annual incidence, this is about 10,000 cases in the United Kingdom, with a standard error, if Poissonian, of 100 thus the rise must exceed 200 It seems unlikely that this figure would yet have been reached, even if the annual genetically effective dose had been 0 1 rem since 1900 and the annual increment to the genetic debt had consequently been 300 Thus though the rise may be real and, in absolute numbers, quite large, it is likely to remain for many years below the limit of statistical significance

OLDHAM AND DISTRICT PSYCHIATRIC SERVICE

H L Freeman
M A, B M Oxon, D P M
REGISTRAR, BETHLEM ROYAL AND MAUDSLEY HOSPITALS, LONDON, S E 5

The Mental Health Act is expected to shift the emphasis in the care of the mentally ill from the institution to the community In Oldham and its surrounding districts this process has already taken place (Keddie 1955, Pool 1958), but, as no full description of this psychiatric service has yet been published, it has not received the attention it deserves With the cooperation of the consultant in charge and the medical officer of health, I was able to spend some time observing and recording my impressions I hope that these will be of interest in considering other schemes of community mental care

The county borough of Oldham lies seven miles north-east of Manchester and has a population of 120,000, most of whom are employed in the textile industry Some 60% of married women—nearly twice the national average—continue to work, and psychiatric services must take account of the fact Again,

1958	1	4	12	19	31

many young people moved south in search of work in the economic depression of the '30s, and there is now a high proportion of elderly people

Surrounding Oldham is a chain of county urban districts with a population of 140,000 No part is more than eight miles from the psychiatric unit and the area covered is thus similar to that described by Leyberg (1959) at Bolton. The public-health services of these districts are provided by the Lancashire County Council, and an integrated psychiatric service therefore needed the cooperation of two large local authorities with the hospital

Start of the Service

Under the National Health Service psychiatric units have been started in many peripheral general hospitals They are an important means of breaking down the barriers between psychiatry and other specialties and of placing all forms of illness on the same footing In the Manchester region, the first step in a programme to develop these units was the appointment of the present consultant at Oldham in 1950 The pattern has since spread and cooperation with local authorities has proved easier from units of this kind than from large and often remote mental hospitals

The general principle for the development of the Oldham service was that abnormal behaviour, rather than merely psychiatric diagnosis, should be the criterion for admission In order that patients might more adequately be treated in the community, the fullest cooperation was necessary with general practitioners and the local authorities

As a result, since 1954 the area has been virtually independent of the large mental hospital (table I) Transfers are exceptions, and in 1958 there were only 4 direct admissions from Oldham itself and 12 from the surrounding districts These patients were sent by general practitioners, many of whom live nearer to the mental hospital than to Oldham, and the district service is not informed before their admission On the other hand, many more patients from outside its area are treated by the service

Cooperation with Local Authorities

Social Work

The most urgent need of the new service, help in social and supportive work, was met by members of the local-authority staffs, who for clinical purposes come under the direction of the consultant psychiatrist The mental-health officers were trained to take over the duties of social workers, they attended outpatient clinics, lectures to nursing staff, domiciliary visits, and group discussions, which they began to take themselves

Case-conferences

When the consultant psychiatrist also became consultant to the local health authority, a weekly case-conference was started for officers of both hospital and local authority This was later extended to area 14 of the Lancashire County Council and similar joint conferences were arranged with the divisional medical officer of health

At these conferences (which are attended by psychiatric and public-health medical staff, mental-health officers, the clinical psychologist, and senior nursing sisters) all admissions and discharges of patients from the area are reported and arrangements made for further care The mental-health officers report on cases notified to them and those which they are keeping under supervision. Information may arrive by a variety of channels and is made available at the conference to all who may be concerned. Special attention is paid to patients receiving day care who are living on their own. Undoubtedly, this regular contact is the most effective form of liaison for the staffs of different services Early referral, with outpatient and domiciliary treatment, have reduced considerably the number of patients admitted under legal order

Child Guidance

In 1957 the consultant psychiatrist took over the child-guidance clinic of the Oldham school health department, holding one session weekly Play therapy and psychological testing are carried out here by the clinical psychologist Domiciliary visits can be made by the mental-health officers, as for adult patients, so the clinic benefits from both local-authority and hospital services and does not work in isolation from either

Hospital Facilities

Inpatients

The Elizabeth Martland unit is in the grounds of a general hospital whose specialist and diagnostic services are available It has 220 beds, of which 136 are for women In addition, 32 male psycho-geriatric patients (including a few day patients) are accommodated in an annexe at a nearby infectious-diseases hospital

One locked ward remains on both male and female sides but there is otherwise no physical restriction. There is a resident medical staff of 2 registrars and a clinical psychologist (holding a joint appointment with the local authority) carries out testing The mental-health officers are responsible for social work, which is entirely a local-authority function

The usual forms of physical treatment are in full use, but individual psychotherapy is scarcely possible on any scale, because the staff-patient ratio is too low Occupational therapy is under the direction of nurses with practical skills and a good deal of furniture is made, which can easily be replaced if soiled. Educational film shows are held frequently, followed by group discussions under medical or nursing leadership Patients may attend a variety of therapeutic groups (Shackleton and Pool 1959) and small parties of schizophrenics are sent out with a male nurse for a day's walking Communication often improves in these circumstances

8 mental defectives are taken daily to the local-authority industrial centre, and it is hoped that they will enter a hostel which is being built there Other patients use the hospital as a night hostel, going out to work during the day

Table II gives some indication of the work of the unit The increase in admission-rate (particularly obvious in the first year) marks the change to an active-treatment policy, reflected also in the increased discharge-rate The sharply increased death-rate for 1958 is due to the influenza epidemic and this may partly be responsible for the reduced number of chronic patients at the end of

TABLE II—WORK OF ELIZABETH MARTLAND UNIT

—	Admission rate	Discharge rate	Chronic patients (over 2 years)	Over 65s at year's end	Over 65s admitted during year	Death-rate
1950	163	148	110	51	44	31
1951	277	221	96	46	44	34
1952	323	276	91	50	59	30
1953	295	274	95	54	42	21
1954	338	297	97	58	47	31
1955	311	290	90	56	65	38
1956	331	318	96	42	74	29
1957	333	312	103	55	78	18
1958	345	306	78	43	98	56

the year Admissions of elderly patients rose in 1958 when the unit began taking them in for short periods, to relieve relatives for holidays and so on It thus includes a number who are normally day patients

Social Clubs

The unit has an active social life and much contact with the life of the town

Twice weekly, social evenings are held, attended by many people from outside One is a Darby and Joan Club, run by the W V S , the other is open to all patients (including day patients and outpatients), ex-patients, relatives, friends, and staff Attendance at the latter averages 150, including some who have been coming regularly for nine years Meetings of Alcoholics Anonymous are sometimes held with the club Some of the mental-health officers attend, but otherwise the club is entirely a hospital service

Day Patients

Day care in the Oldham service is directed primarily to the needs of elderly patients Of 193 day patients, 103 were over sixty years, most of them with a diagnosis of senile dementia This contrasts with some other day units, in which depressive illnesses predominate and few senile cases are treated (Harris 1957, Smith and Cross 1957, Freeman 1959) Even the nearby service at Bolton treats few senile day patients

One reason for the preponderance of elderly patients is probably the admission policy Where a day unit is geared to the treatment of neurotic and affective disorders, senile patients will be unwelcome, because of their chronicity and because they will tend to influence the therapeutic atmosphere unfavourably (Craft 1957) Conversely, a unit where there is a high proportion of senile patients is less likely to be regarded as suitable for young neurotics, who may well find it depressing Again, the population of Oldham gives an impression of stolidness and mutual support which suggests that severe neurotic disorders may be less prevalent than in some other districts Whether the existence of a different kind of day hospital would attract previously undisclosed cases is a matter for speculation Blacker (1946) has pointed out that the attitude of general practitioners to units of various types can affect the apparent incidence of different kinds of cases

Day care arrangements at Oldham are flexible, so as to allow for the needs of relatives Some patients attend seven days weekly Transport of these patients is a considerable burden on the local authority, but their journeys are confined as far as possible to " off peak " hours Until recently, there was no separate accommodation for day patients, but a garden pavilion has now been converted to take about 30 female psycho-geriatric patients, and similar facilities are to be provided for the men

Outpatients

15 sessions are held weekly, though the medical staff is so small 2 of these are taken by a clinical assistant, who forms a link with the local industrial rehabilitation unit, of which he is the medical officer Evening and Saturday sessions allow patients to attend early in the illness, without loss of work Two E C T sessions are held weekly and psychotherapy is given as far as possible

Both nurses and mental-health officers spend a period at the outpatient department, attending interviews and helping with case-histories A similar arrangement in East Anglia has given excellent results (Pargiter and Hodgson 1959) The social work of the mental-health officers is valuable if patients do not keep their follow-up appointments

The average annual total of outpatient attendances is now about 5000 After reaching a peak of 415 in 1956, the number of new cases fell to 386 in 1957 and 314 in 1958 This may perhaps be interpreted as the effect of an established service, once it has overcome the backlog of cases for which facilities were not previously available The peak of new cases in 1956 is almost exactly the same as the number treated by the Bolton service in 1957 from a population of almost identical size (Leyberg 1959)

Domiciliary Visits

These are made by the consultant, usually accompanied by a mental-health officer The actual number is about 350 yearly, but most are informal Many are to elderly patients on day care who have missed attendance A visit will often reveal difficulties in the home Timely help may obviate admission or confinement to the house Each mental-health officer makes about 1000 home visits yearly, and they are the most important part of his work Because of this, visits by nurses on the Worthing pattern (Carse 1959) are not needed

Discussion

In altering treatment policy, one must ensure that the change is not spurious, merely shifting responsibility from one authority to another At Oldham there has been no increase in local beds, except for the psycho-geriatric unit for 32 cases Yet whereas practically all patients needing treatment used to be transferred to the neighbouring large mental hospital, this number is now a mere trickle Very few patients have been transferred to mental-deficiency hospitals and part-III accommodation

The number of psychiatric beds in use, at 1 per 1000 of the local population, is about a third of the national average This suggests that an extension of community care, using peripheral psychiatric units, with an emphasis on outpatient clinics, domiciliary visiting, day treatment, and local-authority services, could considerably reduce the work of the large mental hospitals It is possible that this might save money, but by no means certain, for adequate community services are likely to be expensive in manpower, buildings, and transport (Colwell and Post 1959)

The main advantage to be looked for, however, is an ending of the segregation of the mentally ill into units which are often remote from their homes This not only causes distress to them and their relatives (who may have great trouble and expense to visit them) but makes it harder for them to return to normal life

Clearly, there is room for much variation in response to local needs A community service can be established in a compact urban area like Oldham much more easily than in a thinly populated district Specialised facilities cannot be available in all peripheral units Also, a unit with a small number of beds is in danger of being clogged with chronic cases However, with more geriatric units and better supportive services in the community, admission might be more selective or for shorter periods

Community services of varying patterns have already come into being in several parts of the country The Worthing service (Carse et al 1958) is provided entirely by the hospital and has no formal links with the local authority In York there is an integrated service, with a psychiatrist appointed jointly by hospital and local authority, but as yet no day-care facilities Nottingham (Macmillan 1958) has been a pioneer in community care, with psychiatric services based on the local mental hospital—which is much less remote than most The Nottingham service offers repeated short-term admissions for chronic cases, which are not excluded from the benefits of community care. But the most suitable unit for the rehabilitation of chronic patients remains a matter of controversy (Baker 1958).

To this evolving picture of community mental care, the experience of the Oldham service can make an important contribution.

My thanks are due to Dr Arthur Pool, consultant psychiatrist to the Oldham and district hospital group, and Dr J T Chalmers Keddie, M.O.H. for Oldham, and their staffs. I am also grateful for information and advice from Miss E M Brook of the General Register Office, Dr J S B Mackay of the Manchester Regional Hospital Board, Mr W A. J Farndale of the Bethlem Royal and Maudsley Hospitals, Dr J H Kahn, and Dr Doris Odlum.

DRUG ADDICTION

THE Interdepartmental Committee on Drug Addiction, whose chairman is Sir Russell Brain, has issued an interim report[1] on two topics: (1) drugs, such as carbromal and bromvaletone, which have an effect on the central nervous system but which are not appropriate for control under the Dangerous Drugs Act, and (2) the incidence and consequence of anæsthetists becoming addicted to the gases and vapours they employ.

Carbromal and Bromvaletone

These drugs, the report remarks, are merely two examples among various drugs at present on sale to the public without restraint, the injudicious use of which may nevertheless be attended by dangers both to the individual and to the community. But their properties are such that they do not qualify for control under the Dangerous Drugs Act, 1951, or the Therapeutic Substances Act, 1956, and the Poisons Board have so far felt unable to recommend them as poisons for control under the Pharmacy and Poisons Act, 1933. The committee accordingly recommended that in general any drug or pharmaceutical preparation which has an action on the central nervous system and is liable to produce physical or psychological deterioration should be confined to supply on prescription. An independent expert body should be responsible for advising which substances should be so controlled.

Addiction to Anæsthetic Gases

The committee agree that, with the apparatus at present in use, the preliminary sniffing of the gases immediately before administering them to a patient is a recognised and indispensable precaution. And to the great majority of anæsthetists such a practice offers no encouragement to addiction. "So far as we can discover less than twenty cases have come to notice over the past eleven years . . . " but in two known instances throughout the country in eleven years patients' lives have been endangered." "We are convinced", the report continues, "that anyone who is addicted to the inhaling of anæsthetic gases or vapours should not be entrusted with their administration . . . the responsibility for dealing with this irregularity rests in the first instance with the anæsthetist's professional colleagues . . . any arrangements made should provide for immediate action by the surgeon if an anæsthetist appears to be incapable of carrying out his duties."

In England Now

A Running Commentary by Peripatetic Correspondents

YESTERDAY morning at the tea-break conversation turned to the Christmas concert. The plaster-room sister deplored the present basis on which consultant appointments were made. It was well known, she said, that such qualities as hard work, ability, integrity, humanity, and charm were no longer considered important, but why couldn't appointments committees at least consider the candidate's suitability as material for the Christmas concert? In a passive not active role, she hastened to explain. Names that rhyme easily, personal eccentricities: large feet, ears, or nose, a beard, a lisp, a drawl, a stutter, dropping the final "g", a bow-tie, a loud waistcoat, gesticulating with hands or shoulders, turning X-rays upside down, twisting the legs round each other, wearing the white coat off one shoulder like a sari, all these, for instance, were clearly desirable qualities.

The idea appealed to me. After all we are a rather dreary lot—hard-working, well-intentioned, but colourless and uninspiring. Since 1948 every selection committee on which I have sat have spent their time trying to judge between identical candidates all trying very hard to conform in every respect to the ideal mean. I thought of the gay and colourful students who became prematurely middle-aged in the quest for promotion; could this early inhibition be the reason for their argumentativeness when they finally reached their goal? I thought of my own seniors between the wars—swashbuckling personalities, physicians who took a pinch of snuff at every bed, surgeons who smoked cigars in outpatients and theatre. Yes, the plaster-room sister was right, we are grey and colourless. I apologised to her, regretted that I could not afford to resign, but hoped that my successor would provide better material. With a ghost of a smile she said that she hadn't meant that at all, indeed she hoped I would not resign—at least not just now. This half compliment was unlike her, so I thanked her and we returned to the outpatients.

My children laughed uproariously at the concert. I seemed to miss the point of many jokes which amused the nurses and residents. I recognised the parodies of some of my colleagues but was bewildered by a ludicrous figure whose eccentricities were loudly appreciated by everyone else.

Only the next day did it dawn on me that perhaps the plaster-room sister had not been suggesting a new principle so much as the restoration of an old one. Before 1948 perhaps selection boards gave bonus points for eccentricities and this admirable habit has merely been in abeyance. All she had proposed was its restoration.

* * *

When I arrived I was met in the mortuary by the senior resident, but it soon transpired that vital clinical information was in the hands of a junior house-officer who had not yet come. I made a noise indicative of displeasure and impatience. "Shall I bleep her for you?" asked the resident. Visions began to form in my mind of some quaint punitive ceremony, carried out late at night in the residents' quarters, using a rubber truncheon or perhaps one of those painful-looking medieval spiked balls attached to a length of chain. Fortunately the house-officer arrived before I had time to pronounce sentence.

Later, while I was browsing over a rather odd piece of lung, and the residents, satiated with morbid anatomy for the time being, were gossiping in a corner, the air was suddenly filled with an eldritch, insistent piping, and they scattered like guilty schoolboys. Seeing my astonishment, the senior resident gently initiated me into the mysteries of the hospital's new call-system.

We really must have one in our laboratory. Then, when I am discussing a missing specimen with a querulous surgeon, I shall no longer need to go to the door and shout "George!" With smug suavity I shall reach for the telephone. "Mrs Ogmore, bleep the chief technician for me, will you?"

---

[1] Drug Addiction. Interim Report of Interdepartmental Committee. H.M. Stationery Office. Pp 8. 6d.

The telephone is generally felt by our profession to be among the major plagues of modern life but its absence a hundred years ago certainly wasted a vast amount of doctors' time and patients' guineas I have been reading the private diaries of a consulting physician in the 1860s who lived in Marylebone and had a high-class practice, including Royalty He would be called, let us say, to Frogmore, by telegram—without any indication of the degree of urgency or any possibility of further inquiries Dropping everything, he would go by brougham to Paddington, take a train to Windsor and then—a cab being unobtainable at the station as often as not—walk across the Park There are hardly any records of his being met by a conveyance At Frogmore he finds a baby with green stools, prescribes for it, and returns to London by the same laborious methods Next day he cannot ring up to inquire but must repeat the performance only to find the baby quite recovered and normal When this has happened several times, a hint is dropped by an equerry that he is visiting too often Even in London there are frequent notes " Visited but found no one at home ", a situation which a telephone call would nowadays have obviated

The other modern—or relatively modern—devices which strike one by their absence are thermometers and baby scales None of the four Royal babies seem ever to have been weighed The first was " small " The second is " larger and heavier than his brother ", and so on The small clinical thermometer was only invented by Clifford Allbutt in 1866 and its more monstrous predecessors would doubtless have frightened out of her wits a Princess who expressed—through a lady-in-waiting—" a little alarm " at the doctors taking out their watches to count her pulse Quinine was the master drug of the period, exhibited for practically everything from orbital neuralgia to " a strengthening medicine " after sea-sickness Except for a variety of preparations of opium, few of the drugs used, other than aperients, would appear to have any potency according to modern ideas and the solemn consultations which, in face of serious illness, resulted in changing from one elegant mixture to another equally elegant and equally harmless fill one with pity tinged with superiority And in 1864 the problems of a royal confinement were complicated by the claims of a lady styled " Purveyor of Wet-Nurses to the Royal Family "

Anxious Patient Oh, Doctor, what is the result of the Test?
Sporting Doctor Ah yes, there's another day to go yet, but Peter May and Barrington are
Anxious Patient I mean did you find any cysts in my stool?

* * *

My nose is pressed down on the grind-stone
My schedule is loaded with stress
My diary teems with appointments
My desk's in a terrible mess
Without any hope of assistance
I ask how much more I can do
I envy the lowly amœba—
Designed to divide into two

When conflict remorselessly rises
Within its primordial soul,
It solves its emotional crisis
By splitting its cellular whole
No ruthless attempt at suppression
Produces guilt feelings inside
It promptly resolves on secession
And gently begins to divide

Its slow pseudopodial motion
Has none of the joy of a walk
Its life must be drab in its ocean—
All wet and unable to talk
Unicellular social position
Is very precarious, it seems,
But the function of binary fission
Belongs to the cosmos of dreams

Letters to the Editor

THE COST OF DRUG TREATMENT

SIR,—May I add a few thoughts to the excellent article by Dr Miller and Dr Smith (Jan 2)? These have come into my mind during recurrent attendances at economy committees

Waste is inevitable and had better be accepted Some is justified because the doctor feels that it is better to give the drug and be on the safe side This is no greater waste than the time laudably spent listening to irrelevant histories, percussing resonant chests, and answering night calls that are not urgent A great deal could, of course, be avoided *if we were not so stupid and ignorant.* But we are as we are made, and if the public wants to attract a better type into the profession they will have to pay them more than we waste on drugs Waste on drugs is preventable in the sense that road accidents are preventable—that is to say, they cannot be stopped

The patients' demand for drugs will increase This was high enough when the bottle of medicine was pharmacologically inactive But as more drugs are known to be effective, fewer patients will be willing to see themselves as the few singled out for whom there is no remedy As the public becomes more sophisticated, so also will the drugs that are needed to satisfy them This is regrettable, but no more so than many other things we have to put up with

The drug bill should be a source of national pride, not shame The public takes the view from time to time that vast sums of its own money should be spent on projects that seem right These activities are not necessarily useful They are regarded more as solemn obligations or demonstrations of status, or even as acts of glory I refer, for example, to pyramids, crusades, cathedrals, governing other people, railways, sports stadia, space, medicine, air lines, or television Now there is no reason why the drug bill should not be put on the list It would mean a change of attitude, but nothing beyond our competence Medicine is already on the list, and so is the production of new drugs, provided it is done only by foreigners We could then regard its steady annual growth with quiet pride, instead of with shame and mutual recrimination

But it may be objected that without restriction the bill would reach intolerable proportions I doubt whether that would happen It seems to be controlled by its own laws of growth, and no doubt would be as unaffected by future praise as it has been by present condemnation

London, W 1 J B HARMAN

SIR,—In their very interesting article Dr Miller and Dr Smith included a reference to the weekly cost of the three main anti-tuberculosis drugs given at home The figures given for streptomycin of 14*s* 5*d* weekly and for isoniazid 1*s* 10*d* weekly are approximately of the order of magnitude I would expect I am, however, extremely surprised at the figure of £1 2*s* 11*d* weekly for treatment with *p*-aminosalicylic acid (P A S)

Based on hospital costs, I had always reckoned that treatment with P A S cost between 3*s* 6*d* and 7*s* (or a little more) weekly, depending on the particular preparation used, and certainly I would expect the cost of P A S to lie between that of isoniazid and streptomycin

I have discussed the figures with our hospital pharmacist and with a local retail chemist, and I have been unable on the most generous estimates of costing to obtain a weekly figure for P.A.S (20 g daily) much in excess of the cost for streptomycin.

Considering the very substantial amount of anti-tuberculosis treatment at present carried out at home, I feel that the figure for this treatment is of some importance, and I would be most interested to know how the figure of £1 2*s* 11*d* is calculated. If it is due to the use of some special preparation I would worry no further, but if it is an extreme example of the working of the system of costing then there is perhaps room for further thought.

According to my own calculations, if, as is usually done, both isoniazid and P.A.S are given in a combined cachet, the weekly cost for both drugs is unlikely to exceed 10*s*. There is of course some economy here with only one dispensing fee for the combined preparation.

Birmingham Chest Clinic. V. H. SPRINGETT

SIR,—I was interested to read that the cost of treating Wilson's disease with penicillamine amounts to about £750 a year. Previously I had been under the impression that phenylketonuria was the most expensive disease.

Provision of diet low in phenylalanine for the treatment of phenylketonuria involves the use of a special preparation of casein hydrolysate from which certain aminoacids have been removed and others added, together with some essential minerals. A special vitamin preparation is also required. The treatment costs approximately £1 per day. Dr Miller and Dr Smith very rightly draw attention to the overall economy when expensive preparations such as these are dispensed from a hospital rather than from a private pharmacist.

Alder Hey Children's Hospital,
Liverpool F. P. HUDSON

THE BRAIN AS A CLOCK

SIR,—I was glad to see that Dr Gooddy (Dec. 26) had written again about the brain viewed as a clock. He is right about this, and it is valuable to have the statement reiterated. What he is saying in effect is that there is a perceptual time and a public time which is agreed on by common consent, but that the two are never identical. There are similarly perceptual and public dimensions of space.

It might be objected that he is stating the obvious and insisting then on going on to explain it, but this would be a shallow, superficial view of the problem, for underlying Gooddy's proposition lies not any trite aphorism but a crucial enigma of existence. In this as in other respects our brains are finite machines sampling a non-finite material. We assume without the slightest justification that time has meaning apart from our private time, and that it is uniform throughout the universe. This is ridiculous and unjustified, as by ordinary astronomical observation it leads to the absurdity of a constantly expanding universe. Why not a contracting time—which would lead to a convergent time-point (with infinitely extended space and velocity) and would then presumably overshoot into an expanding time with constantly contracting space and slowing velocity? This would lead back to the primordial atom—which is, according to half of our physicists, where we started from.

In all these *apparently* absurd ideas Gooddy's clock is one of the few firm points. We could build machines which would not only indicate the passage of time but note it as well. We could give them variable goal-seeking circuits and we should have non-living analogies with our own minds. Unless we appreciate the fact that the mind has such a finite substratum we shall never begin to understand or overcome the exact nature of its limitations. What Gooddy's clock stands for is the pendulum of our neurophysiological age. He is ahead of his time—if there is a time.

HODGKIN'S DISEASE: A MATERNAL-TO-FŒTAL LYMPHOCYTE CHIMÆRA?

SIR,—This new approach by Dr Green and his colleagues (Jan. 2) to the ætiology of Hodgkin's disease is an interesting one, particularly to me, as it attempts to utilise some aspects of the immunological theory of cancer. As with other attempts of this nature the authors have sensed the general idea but misunderstood the nature of the antigens believed to be concerned. The "identity proteins" thought to be lacking in the cancer cell are the tissue-specific substances recognised by immune techniques as tissue-specific antigens. These, which are almost certainly lipoprotein complexes, are located in the microsomal fraction and very probably in the endoplasmic reticulum. We[1 2] shall shortly be presenting further evidence that this is the region where carcinogens may specifically operate.

Now in their paper on Hodgkin's disease Dr Green and his colleagues are throughout discussing homologous or iso-antigenic immunity—i.e., the antigenic difference between individuals of a mixed strain. It is true that the work[3] on which my views were originally based seemed to show that carcinogens modified a cell component so as to make it iso-antigenic and therefore treated by the body as "not self". It was this property which led to the idea[4–6] that a similar modification might occur in surface tissue-specific antigens resulting eventually in an immune adaptation by loss of the modified antigen. Iso-antigens are common to all cells of one individual and could not be primarily concerned in an often organ-specific process like carcinogenesis. Their role in the homotransplantability of tumours is another story closely related to tissue transplantation in general.

Assuming that the lymphomas in radiation chimæras are the result of immunological aggression of either donor or host lymphocytes towards each other, what is a possible mechanism? We are dealing here primarily with homologous immunity, and iso-antibodies formed by donor cells would be absorbed by any type of host cell, including of course lymphoid cells, and give rise to the symptoms of homologous ("runt") disease, but this, according to my theory, would not be directly related to tumour formation. It is, of course, possible that antibodies may be formed against lymphatic tissue-specific antigens as a result of a homologous challenge just as antibodies are formed after heterologous challenge. Whether produced by recipient or donor lymphocytes or both, the result could be similar in that neoplasia of either type might ensue. This is supported by the finding[7] that lymphomas arising from either type do occur in irradiation chimæras.

Whether or not such explanations are valid remains to be seen. What does seem clear is that immune reactions play some part, for lymphomas arise only in chimæras produced by homologous, and not by isologous, injection of bone-marrow. Moreover the similarity in the effects of homologous disease and of lymphoid tumours both in man and animals[8] is too close to be dismissed lightly as a chance relationship.

My reason for writing is firstly to congratulate the authors of the communication on an ingenious idea, and secondly to try and make clear one aspect of the immuno-

THROMBOTEST METHOD FOR THE CONTROL OF ANTICOAGULANT THERAPY

SIR,—There are two main factors to be considered in the choice of a method for the control of anticoagulant therapy firstly, the results of the method should be reasonably correlated with the patient's tendency to bleed, and secondly, the method must be technically simple and rapid Of the present methods the prothrombin and proconvertin (P & P) method of Owren and Aas [10] fulfils the criteria better than any other This method has not gained the widespread popularity it deserves mainly because many small laboratories lack the staff and facilities for making the reagents Since the total number of patients receiving anticoagulant drugs is likely to rise, it is essential that a good method of control be available to all units both large and small

The thrombotest method recently introduced by Professor Owren (Nov 7) appears to fulfil this need He claims that the method is superior to the P & P method, as it is sensitive to both the intrinsic and extrinsic coagulation systems, whereas the P & P method is sensitive only to the extrinsic system The method is extremely simple, as only one reagent is necessary and this is available commercially in a freeze-dried form, also the method can be applied to capillary blood, whole citrated blood, or citrated plasma

I have recently had the opportunity to test three commercial batches of this reagent and to compare the method with the P & P method using the blood of patients receiving anticoagulant drugs The brief details of the technique are as follows

CONCENTRATION (%) FOR PLASMA FROM LUSTEROID TUBES

Case	Batch 27	Batch 28	Batch 30
1	10 5	8 0	7 6
2	11 5	10 0	10 0
3	18 0	18 5	20 0
4	13 0	13 0	8 6
5	20 0	20 0	17 5
6	10 0	9 0	7·4

(1) The ampoule of freeze-dried material is reconstituted with distilled water if capillary blood is to be used, or with weak calcium chloride solution if citrated venous blood or citrated plasma is to be used

(2) 0 1 ml of the appropriate blood sample is added to 0 5 ml of the reagent in the waterbath at 37°C

(3) The clotting-time of the system is recorded

(4) The result is read as "percentage activity" from a dilution curve supplied with each batch of reagent

As the method was found to be very sensitive to glass contact activation, Owren recommends that all blood samples (except capillary samples) should be collected in 'Lusteroid' tubes The dilution curves provided are for whole blood only, therefore if citrated plasma is used it must be diluted before testing by adding three parts of plasma to two parts of 0 85% sodium chloride solution

The first stage of the investigation of the method was to check the dilution curves supplied with the material For three batches of reagent, it was found that dilution curves made on whole blood and on plasma collected in siliconed or lusteroid tubes agreed very closely with the dilution curves supplied The clotting-times of the dilutions were very slightly longer than those expected from the curves provided, giving results on abnormal test samples 1–2% higher than would have been obtained from the dilution curves provided with the reagent These dilution curves have since been found to be in error Owren [11] on rechecking has found that his dilution curves do in fact agree very closely with mine

Dilution curves prepared from whole blood or plasma collected in ordinary glass tubes gave results rather different from those provided The clotting-times of the diluted samples, although more variable than the siliconised samples, were

11 Owren, P A Personal communication, 1959

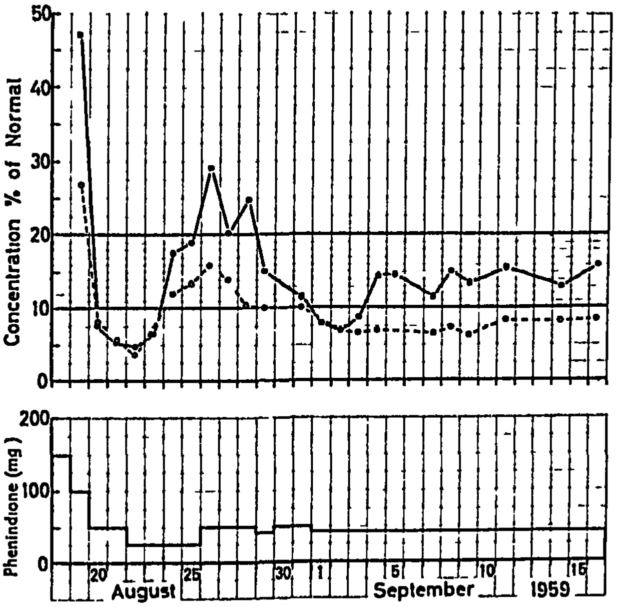

Fig 1

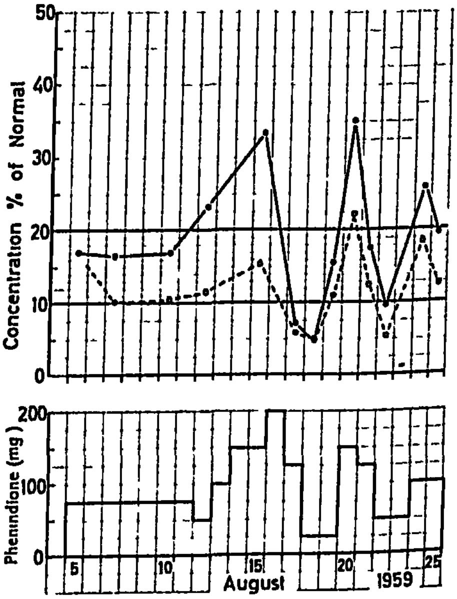

Fig 2

●———● P & P method ●- - - -● Thrombotest

Figs 1 and 2—Comparison of thrombotest and P & P methods on patients receiving phenindione The parallel lines indicate the therapeutic range accepted for the P & P method in this laboratory generally much shorter As test samples collected in ordinary glass tubes also gave variable and sometimes unpredictable results, the remainder of the samples for the investigation were collected in silicone or lusteroid tubes

A short experiment was made to determine if each batch of reagent gave similar results with blood from patients on anticoagulants The results for plasma from lusteroid tubes are given in the table, whole blood in lusteroid tubes gave similar results

Some 350 samples from patients on anticoagulants were compared by the thrombotest method and by the P & P method The results in general showed very close agreement. Two examples are shown in figs 1 and 2 Fig 1 gives a good example of a case in which the appropriate dose of anticoagulant was rapidly determined and a constant dosage maintained, whereas the example in fig 2 illustrates the effect of altering the anticoagulant dosage by large amounts It can be seen from the examples that the two methods give basically the same result, except that the thrombotest method appears to be less sensitive in the near-normal range. Also the results appear to be generally a little lower than the P & P method as carried out in our laboratory It is a remarkable testimonial to the P & P method that a modification of the original technique,[12] which has never been compared directly with that of Owren, should give results in such close agreement with the new method which is directly calibrated by Owren.

The thrombotest method is commendable for its extreme simplicity and for the fact that three types of blood sample may be used It appears to be subject to only small random variations, and the difference between various batches of the reagent is negligible provided that siliconed or lusteroid tubes are used for the collection of samples The P & P method appears to be the more sensitive method in the near-normal range, probably because a 1-in-10 dilution of plasma is used in that test The thrombotest method is affected by heparin, whereas the P & P method is not very sensitive to the heparin concentration likely to be encountered in blood samples The thrombotest method appears to be a major technical advance in the routine control of anticoagulant therapy, both short and long term, though some large laboratories may prefer the P & P method for its greater sensitivity in the near-normal range

HÆMATOLOGY IN BRITISH HOSPITALS

SIR,—Many will agree with Professor Dacie, in his excellent article of Jan 2, that hæmatology should be recognised as a specialty which requires an organisation distinct from pathology and medicine Indeed, a decade ago, the following statement appeared in a leading article[13] of *The Lancet* "Today hæmatology can fairly claim any advantages obtainable from full specialist status"

In the large centres, at least, the hæmatologist and his staff ought surely to be allowed to confine their activities to laboratory and clinical hæmatology, because this alone is likely to keep them very fully occupied. Yet it appears that very few consultants have been appointed hæmatologists as such. Most of the advertisements one sees are for pathologists with an interest in hæmatology, and occasionally physicians with an interest.

An appreciable number of present-day hæmatologists were trained in their early postgraduate years as general clinicians, and it may well be that this is much more important than a training in other branches of laboratory medicine Ideally, of course, the wider the laboratory and general clinical training before specialisation in hæmatology the better, but the most important qualification for a consultant in hæmatology should be his extensive clinical and laboratory experience in hæmatology itself

Some hæmatologists who themselves are clinicians appreciate having a free choice of physician to consult when confronted with a difficult general medical problem. Under Professor Dacie's scheme, such a choice might prove to be restricted to one physician already on the staff of the hæmatology department

In order to obtain maximum efficiency from a hæmatological unit in the ultimate service of the patient, I am sure that clinical hæmatologists should have their own laboratories and outpatient and inpatient facilities These would ensure a satisfactory service for patients referred to them by colleagues for diagnosis, for treatment, or merely for follow-up While a few are already fortunate in having at least some of these facilities, there is no doubt much room for improvement in all hæmatological units

I am grateful to Professor Dacie for providing an opportunity for discussion of some of these problems

THE ABNORMAL APPENDIX

SIR,—I should like to recall an astonishing remark of the late Professor Sauerbruck in Berlin at an international postgraduate meeting He said that 96% of appendicitis can be cured by conservative treatment, but because of the remaining 4% we are obliged to operate on all the 100%

Düsseldorf
TH OLBERT

INTRATHECAL PHENOL AND RELIEF OF SPASTICITY

SIR,—May we answer the question posed by Dr Liversedge (Jan 2)? The idea was conceived in April, 1957, on hearing Dr Nathan read his excellent paper to the Association of British Neurologists on the treatment of pain with intrathecal phenol and the explanation he proposed as to how this method, originally suggested by Maher, achieved its effect After some very helpful conversations with Dr Nathan on the question of technique, we immediately started to select patients for this trial and to subject them to a period of treatment with relaxants and physiotherapy until we were certain that no further help from these methods could be achieved before we submitted them to intrathecal injections

The first patient was actually admitted for an intrathecal injection of phenol in February, 1958, but eventually elected not to have this experimental treatment At her request she was treated with neurectomies and tenotomies, but was in hospital for over six months with little improvement. This underlined the necessity for finding a more simple and less time-consuming method of dealing with flexor spasms and spasticity and emphasised the great advantage of the method of treatment under discussion. The first patient in our present series to receive an intrathecal injection of phenol was thus treated in September, 1958, and as the method does not demand prolonged inpatient treatment we had already nearly reached the halfway mark in our series by March, 1959

In reply to Dr Lipton (Jan 2) our criteria for selection of concentrations of phenol in 'Myodil' have been as follows

5% was used once only, proving sufficient in a child of 2 with a cerebral diplegia.

7½% was used in ambulant patients with troublesome spasms and in whom severe spasticity was not a problem.

10% was used in ambulant patients with spasms and incapacitating spasticity and little if any sphincter disturbance.

---

[12] Allington M. J *J clin. Path* 1958, 11, 62.
[13] *Lancet*, 1950, ii, 404

15% was used in the bed-bound who retained some voluntary power but no sphincter control

20% was used only in the total and irrecoverable sensory and motor paraplegia

P GAUTIER SMITH

SENSORY DEPRIVATION

SIR,—Some recent work by non-psychiatric disciplines may widen the scope of your leading article of Dec 12

The psychiatric observations on sensory deprivation, begun in 1954 at McGill,[1] have been followed up independently in other departments of the same university, and it is now apparent that the need for adequate sensory nourishment is not just an isolated phenomenon of the "higher" centres, but is rooted deep in the brainstem Prof B D Burns, of the department of physiology, has shown in a most elegant and convincing manner how the respiratory centre itself, so long thought to be the possessor of an intrinsic tonic activity, is no exception to the rule that something must come in before something can go out, for when deprived of an adequate traffic of afferent stimuli its motor activity ceases[2]

In the department of anæsthesia we have been able to demonstrate a similar pattern of response at a lower spinal level Activity of the phrenic reflex arc (centre C3, C4, C5) is readily abolished by blockade of afferent stimuli up to a spinal level of T1[3] Presumably the mechanism is the same in both cases—a vital reflex activity can sleep quietly in its den if the total "pool" of neuronal visitations through and past its doors is inadequate to awaken it

Perhaps the dysphoric feelings which arise during sensory isolation are merely a wholesome reaction attempting to supply an essential commodity from within when outside sources fail

Montreal

P R BROMAGE

TOLBUTAMIDE AND ANGINA PECTORIS

SIR,—In your issue of Dec 19 Professor Inder Singh and Professor Bardhan describe the beneficial effect of tolbutamide in angina pectoris, as observed in diabetic and non-diabetic patients

We have studied the effect of carbutamide on the electrocardiogram in 4-hour experiments, in diabetic and normal subjects (3 g orally) and in pancreatectomised and normal dogs (0 5 g per kg intravenously)

We observed in *all groups* a considerable reduction in heart-rate, which was not related to the changes in blood-glucose and serum-potassium levels In animal experiments we found a 30–50% decrease in heart-rate, which could be averted by bilateral cervical vagotomy or administration of atropine

In the animal experiments we observed in most cases a transitory inversion of T waves and a prolongation of the QTc intervals These phenomena took place both in hypopotassemia and during infusion of KCl, they were not related to blood-glucose levels, and they could not be influenced by vagotomy Vagotomy could modify T-wave inversions after carbutamide, but carbutamide given 1 or 24 hours after vagotomy caused the same T-wave inversion as in the normally innervated heart The same applied to the QTc prolongation

These data[4,5] seem to indicate that E C G changes after carbutamide may be partially due to the effect of the vagus nerve, but a direct effect on the myocardium cannot be excluded

We are aware of the fact that *acute* changes taking place after carbutamide administration cannot be compared with results achieved by chronic treatment with small doses of tolbutamide But (1) carbutamide is a cumulative drug, (2) it is used mostly by older patients in whom the danger of cumulation is greater, (3) determinations of plasma levels of carbutamide are not performed routinely, and (4) in older diabetics the myocardium is frequently not intact so we think that the occasional heart complaints and the E C G s of patients treated with carbutamide should be regarded very carefully

TREATMENT OF BLEEDING PEPTIC ULCER

SIR,—The problem of acute gastrointestinal hæmorrhage, recently discussed in your columns, draws attention to the need for early diagnosis A ward barium meal using a mobile apparatus[1] has been used in the study of 200 patients admitted with hæmatemesis to the General Infirmary at Leeds in the period 1956–58 This method, which does not disturb the sick patient, is simple to carry out, unassociated with complications, and has yielded positive diagnostic information in a high proportion of patients studied[2]

It is reassuring for the surgeon to know the site of bleeding, enabling him to carry out a planned procedure, and directs attention to a specific lesion, thereby saving time which might otherwise have been spent in searching for the bleeding site

Dublin

DERMOT F CANTWELL

AUTOIMMUNE HÆMOLYTIC ANÆMIA DUE TO PHENACETIN AND *p*-AMINOSALICYLIC ACID

SIR,—We read with interest the article of Jan 2 by Dr MacGibbon and her colleagues We have recently encountered a somewhat similar case where the causal drug appeared to be salicylazosulphapyridine ('Salazopyrin')

The patient was a married woman of 26 years being treated for ulcerative colitis She was receiving a second course of salicylazosulphapyridine (1 g three times a day) when after three weeks of this therapy it was noticed that her hæmoglobin level had fallen from 10 6 to 8 g per 100 ml Investigation of her anæmia revealed microspherocytes, a reticulocyte count of 10%, and absence of haptoglobin from the serum. The urinary urobilinogen was increased but the serum-bilirubin remained at 0 4 mg per 100 ml Neither Heinz bodies nor lupus-erythematosus cells could be demonstrated, and the direct antiglobulin test was negative Examination of the serum, however, showed it to contain a factor which in the presence of either salicylazosulphapyridine, sulphapyridine alone, or sulphamethazine was capable of sensitising both the patient's red cells and normal red cells from a donor of the same group, agglutination occurring at low dilutions of antiglobulin serum The antiglobulin test remained negative after the patient's cells had been incubated with sodium salicylate and patient's serum, and with salicylazosulphapyridine and normal serum

It seems therefore that the autoantibody mechanism may also be responsible for some of the hæmolytic anæmias induced by sulphonamides In the two cases of drug-induced autoimmune hæmolytic anæmia reported by Dr MacGibbon and her colleagues the direct antiglobulin test was positive, but in our case the test was negative The performance of an indirect antiglobulin test on the patient's serum with the addition of the suspected sensitising agent may therefore be of diagnostic value in the investigation of acquired hæmolytic anæmia

GÖDEL'S PROOF

SIR,—Your article on Godel's proof (Jan 9, p 107) was interesting and important but it did not fully work out the psychological implications

Gödel's proof implies that human reason is incapable of achieving a watertight proof of its own rationality, even in the strict language of formal logic. The obsessional, however, demands absolute certainty, he is unable to accept the truth of Gödel's theorem.

Your article suggests that an obsessional would be cured if he could be made to accept a dogma and that the cultivation of a transference relationship establishes the analyst as an acceptable source of dogma. Surely if this happens the patient is not cured but merely has replaced one set of dogmas by another and still remains fixed to the delusion that absolute certainty can be reached by human thought.

This may be the reason why some analyses are so long, the analyst makes himself a source of dogmas so is unable to dissolve the transference relationship satisfactorily, the patient desiring the source of dogma never to dry up

The only cure for this is for the analyst to cure himself of his own obsessions and so cease feeding the patient with dogmas The analyst will then be free to tackle the more basic problem of the obsessional—which is, why does he demand absolute certainty

London, W 1 J M HEATON

NATURAL HISTORY OF CAVERNOUS HÆMANGIOMATA

SIR,—Dr Simpson (Dec. 12) is to be congratulated on his excellent paper and follow-up of cavernous hæmangiomata and, judging by previous correspondence, it seems that the lesson to be drawn from his study has still to be learnt

I cannot see why it should be necessary to interfere surgically with a lesion which is going to disappear spontaneously without leaving a trace, as is the fate of the overwhelming majority of these lesions Atrophy, hæmorrhage, and ulceration have, in my experience, been extremely rare and usually occur only when the lesion is awkwardly situated (such as in the napkin area, but even there I have found that complications can generally be avoided by proper care) or when the lesion is of unusual size I would agree with Mr Denis Browne (Jan 2), however, that surgery is the only satisfactory method of interference with these lesions, and I consider that radiotherapy is *never* justified

I have seen several cases of radiodermatitis following treatment of these lesions, and this is not at all surprising if doses of the order of 1800r are given in the treatment of these lesions, as would seem to be the practice of Dr Colin-Jones (Jan 2) and his radiological colleague Most dermatologists now consider doses in excess of a total of 1000r, whether given in one dose or several, run the risk of producing radiodermatitis, with skin atrophy, telangiectasis, and disordered pigmentation, and ultimately of carcinomatous change

Apart from this, we must consider the genetic risks associated with radiotherapy in childhood, and if it is true that a single quantum of X-rays is sufficient to produce a mutation in the germ cells of mammals, including man, then radiotherapy should be reserved for those conditions in which it is the only treatment or for patients in the post-reproductive epoch

There would seem to be very few conditions where radiotherapy of dermatoses is necessary in childhood and cavernous hæmangiomata are certainly not numbered among these

I am very surprised to learn from Dr Colin-Jones that these lesions are common in adults I had the opportunity during the last war of inspecting well over 100,000 airmen, and I cannot recall having seen *a single cavernous hæmangioma amongst them* In fact, apart from sclerosing hæmangiomata, which have a very different ætiology, I cannot recall, in sixteen years' dermatological practice, a single case of these lesions persisting into adult life, indeed, I cannot remember a single case in which the lesion had not disappeared by puberty

I am sure that it is only by careful study such as Dr Simpson has carried out that we are going to be able to show conclusively that very few of these lesions, when left alone, will give rise to any real disability, and that they in fact do spontaneously disappear

If a decision is made to interfere after a lesion has been present for an arbitrary period then we would never know their true fate, and I am sure that Mr Denis Browne will agree that Dr Simpson has made a contribution towards the true understanding of the natural history of these lesions and seems to have established beyond reasonable doubt that the overwhelming majority of these lesions do, in fact, spontaneously disappear, and further that the residual defects are few and rarely disfiguring

Surgery inevitably carries a risk with it, if only of an anæsthetic death, and a life lost in the removal of what is only a cosmetic blemish and never one imperilling life would seem to be a life lost for no very good reason.

Parents and relatives are apt to exert pressure on the family doctor because they do not like the look of the lesion, but I have found that careful explanation of its nature and its inevitable tendency to disappear spontaneously *sooner rather than later*, helps to keep up their morale pending this happy result.

I consider it would be a most retrograde step in the management of these lesions if once again these children are to be submitted to radiotherapy, with all its potential genetic consequences—apart from the risk of subsequent radio-atrophy and, even, carcinoma—or to unnecessary surgery, and I hope that every dermatologist who has closely followed his cases will publish his experiences

Dr Simpson is following in the footsteps of Dr Lister in the West Country, who, more than twenty years ago, persuaded dermatologists to leave these lesions alone We now have to educate the recalcitrant few who still interfere with them and to teach the surgeons that Nature nearly always achieves better results than they can, although we may need their help and be grateful for it in the very exceptional case

Guy's Hospital,
London, S E 1 E J MOYNAHAN

SIR,—The fact that these lesions disappear spontaneously after some years is an argument against dangerous or mutilating treatment but not against treatment of any kind

Occasionally treatment is indicated by the location of the lesion as on the eyelid or lip The complications of hæmorrhage, ulceration, and infection with resultant scarring are uncommon but such a nuisance when they occur that they are worth avoiding Above all these hæmangiomata are disfiguring, children can be very frank about blemishes on each other and many a child, untreated, will reach an age in which unhappy embarrassment will be caused. Most of all, consider the mother whose delight and pride in her baby includes its physical appearance, the firm reassurances of the doctor may prove right in the end but do not prove the blemish is not there—there to stay for some years

Application of carbon-dioxide snow for fifteen seconds will quite abolish a small superficial lesion and will gradually improve nearly all the rest Those who use this treatment may find it so simple, safe, and effective that one wonders why anyone should want to withhold it

The Middlesex Hospital,
London, W 1 F RAY BETTLEY

SIR,—*Primum non nocere* first not to harm In other words, never write " Operation successful, patient died " Or, as we must regard the deaths on M1 as justified in the interest of speed, are we to regard carcinomas as justified in the interest of that other modern idol, cosmetics? We should not be swayed towards potentially dangerous treatment by occasional doubts of natural resolution

Summerfield Hospital,
Birmingham
ROBERT J HETHERINGTON

CASE-FATALITY IN TEACHING AND NON-TEACHING HOSPITALS

SIR,—The further contribution (Jan 16) from the social medicine research unit at The London Hospital is a welcome stimulus, but of course will arouse ill-informed lay, political, and medical political opinion It would be very helpful to know, particularly in the prostate series, whether the case-fatality rate was at its height in night emergency operations In the period under survey this had become an exciting new adventure for the average registrar

The N H S covers its deficiency with respect to emergency services by saying that there is a surgeon " on call " He may live 20 miles from the hospital, have perhaps three sessions a week or less at the hospital, and yet be expected to provide non-stop service day and night for one week in three For years we have waited for a solution to this problem, and still we wait for the working party's report After that we shall wait for action upon the report With the emergency service of the country undertaken largely by overworked registrars, many of whom have been trained outside the British Isles, it is little wonder that the case-fatality rate is higher than it ought to be In many places the registrar is in fact more skilled than his consultant supervisor in some of these emergency procedures, but it is judgment that is perhaps more important than craft skill in prostatectomy

What has been said about surgery applies equally to the night anæsthetic services in the non-teaching hospitals

London, S E 19
D F ELLISON NASH

WITHHOLDING OF SICKNESS BENEFIT

SIR,—Mr Hervey's experience (Dec 19) of the withholding of sickness benefit has also been mine, although the delay in submitting the medical certificate was a matter of only a few days—not that the length of time should make any difference I gave a sound matter-of-fact reason for the unavoidable delay, but it was not, of course, accepted and a protest was followed by typewritten foolscap sheets bearing copies of the correspondence, with an invitation to appeal against the decision if I wished

The official forms warn the intending suppliant (I am sure this is the only word to use when dealing with any department of Government) who hopes to attain his rights that any delay in submitting the certificate(s) *may be* followed by a withholding of benefit if an adequate reason is not given for the delay The difficulty is that nobody has ever been able to discover what *is*, in the opinion of the local manager (or whoever it is who makes these arbitrary decisions to refuse payment), a good reason for *not* refusing payment, if indeed there *is* a good official reason This is a dark bureaucratic secret But one suspects that the words " may be " are a Governmental euphemism for " will be "

Any attempt to obtain redress is made so cumbersome by the necessity to appear before an " appeal court " to show cause why you think you ought to receive your just deserts that you cannot help thinking it is done deliberately to discourage you I believe that the strategy is generally successful, but in any case one has no confidence that the decision will be reversed and the matter is allowed to slide as a waste of time and effort, either because of illness or because, when you have returned to work, you are too busy to spare the time on what you are certain is a foregone conclusion

If bureaucratic chicanery is denied and no suspicion or charge of dishonesty is held or preferred against the medical profession or the public, then the Minister should state, without verbal woolliness or equivocation, *why*, in the name of common sense or even of honesty, payment of benefit should not be made, no matter what the length of the delay in the receipt of the certificate

Folkestone
B G EDELSTON

HOTELS OR HOSPITALS?

SIR,—Mr Stallworthy's deduction (Jan 9) that convalescent hospitals would result in economies appears to be based on a misunderstanding of the meaning of present methods of hospital costing The policy would not reduce the cost of the hospital service and would, in fact, slightly increase it as the following argument shows Let the convalescent annexe be built adjacent to the corresponding acute block, the cost will not be more than if it be built at a distance and will, in fact, be less because some of the services can be shared with the acute hospital Now let a door be made between the acute and convalescent wards, will this increase the cost of either? Looking at the problem the other way round, the cost per bed of the hospital keeping convalescent cases in acute wards is derived from the cost of the first few days of admission (high), and the cost of the later period of stay (low) Remove the patient at the point between these stages and the cost per bed of the acute hospital will automatically rise in proportion

The way to reduce the cost per patient treated lies in other directions which Mr Stallworthy has also indicated these include providing services such as radiology, pathology, operating-theatre space, &c, only to the level required by the acute cases and ensuring that patients are not kept in hospital longer than is absolutely necessary

Convalescent wards always disrupt the nursing continuity and the medical continuity on the resident staff level Experience sadly teaches that it also breaks the consultant continuity because visits to convalescent wards tend to be rare and mainly to clear beds This creates a " dump " where patients suffer from too little clinical activity The whole conception of postoperative transfer to convalescent wards is thoroughly undesirable on clinical grounds But most importantly it is a further heavy blow to the already atavistic doctor-patient relationship in our hospitals

The Royal Infirmary,
Sunderland
D A SANFORD

SIR,—I have read Mr Stallworthy's article with great pleasure It is an excellent contribution to the thought that is needed if money on new hospitals is to be well spent

Mr Stallworthy writes as director of a gynæcological unit and believes that hospital treatment of medical and surgical patients could be carried out more economically and at least as effectively as at present if acute hospitals were smaller and were supplemented by convalescent annexes He gives experience from the department of gynæcology of the United Oxford Hospitals to support his belief and asks for an experimental pilot trial in which doctors, nurses, and administrators could test the plan for different types of hospital work and find the advantages and disadvantages

Once large ideas such as these enter the mind other important questions arise. How many patients are better for hospital treatment and by how much are they improved? Is the attention of hospital doctors too much concentrated on surgical and medical techniques to the neglect of other means of improving patients' wellbeing? Can the prevention of diseases be hastened by closer collaboration of general practitioners, hospital doctors, public-health doctors, and research-workers?

These problems are being studied in other countries and the rebuilding of hospitals is a good opportunity to study them here Our patients are showing an interest in these matters A few months ago, the Duke of Edinburgh challenged us in his presidential addresses to the Canadian and British Medical Associations to take a wider interest in the health—rather than the illness—of the community

London W 1 J M **Alston**

ÆTIOLOGY OF LEUKÆMIA

Sir,—The letter of Jan 9 by Dr Nowell and Mr Hungerford was most interesting Whether or not autonomy of *acute* leukæmic cells is specifically indicated by an abnormal chromosomal pattern, abnormalities in the chromosomes of *chronic* granulocytic leukæmia are—in my opinion—not in contradiction with the theories exposed

Secondary alterations in the "chronic" cells' genetic material are apt to arise sooner or later on these cells' way to ultimate autonomy

Gorinchem N H D **Schoyer**

BREECH PRESENTATION AND DELIVERY

Sir,—In your leader of Jan 9 you do not make a strong enough case for the abolition of external cephalic version before labour

In this hospital White[1] reported a 5% fœtal mortality associated with this manœuvre, and from 1950 to 1956 652 versions were attempted amongst 9681 deliveries In 480 of these cases in which this was performed without anæsthesia, the mortality due to version was 1 (0 21%) and in 172 cases with anæsthesia 3 (1 7%) During this period there were 119 uncomplicated breech deliveries with 2 deaths (1 6%) In spite of these 652 attempts at version in this clinic, the incidence of breech presentation is 2 6%

Steptoe and Moore[2] reviewed 50,255 deliveries and found the incidence of breech delivery to be 2 8% when external cephalic version was never performed (before labour)

The safety of version is irrelevant since it often cannot be shown that it significantly reduces the incidence of breech presentation

Obstetric Hospital,
University College Hospital,
London, W C 1 J D **Martin**

Sir,—Your leading article states

> "The need for cæsarean section in breech delivery will vary from one hospital to another Hospitals deal with selected clinical material, and the rate of cæsarean section will depend on the ages, stature, and parity of the patients and the weights of their babies and is likely to be high when there are many emergency admissions Study of a total community would give a much truer picture of the management and results of breech presentation in any particular area, and would make valid comparisons possible Unfortunately, there is at present little enthusiasm for such an epidemiological approach to obstetrics"

The results of 1 2% corrected fœtal loss, in association with a cæsarean-section rate of 16% as reported by Hay[3] for St. David's Hospital, Bangor, could in fact be used as a basis for such an epidemiological study The Bangor figures represent as closely as it is possible to visualise what can be expected in "any particular area" or "total community" from a highly organised area obstetric service. This statement is based on the following facts

(1) St David's Hospital is the only fully equipped maternity unit serving the counties of Caernarvon, Anglesey, and Merioneth The population catered for is 215,000 Because of geographical position and the hospital's popularity it is unlikely that many cases from the area are delivered outside the region

(2) 75–80% of all pregnant women in the area are supervised antenatally at ten peripheral clinics and three hospital clinics by medical personnel based at the main hospital at St David's

(3) 84% of all cases in the area are delivered in hospital—either at the main hospital or in the five peripheral general-practitioner hospitals

(4) All cases of previously undiagnosed breech presentation arriving at the peripheral hospitals are referred to the main hospital

(5) In the area there is a very high standard of cooperation between the general practitioners, district midwives, and the hospital staff, and all breech presentations seen on district are, where possible, referred to the main hospital for delivery

It is unlikely, therefore, that in the area there are many cases of breech presentation who do not ultimately come under the hospital's supervision.

St David s Hospital, Bangor, North Wales **David Hay**

ATYPICAL HAPTOGLOBIN PATTERNS IN TUMOUR PATIENTS

Sir,—I should like to add some further comments to my preliminary report of Nov 28

I have now learnt that the sera of cancer patients have an increased haptoglobin concentration, and thus the atypical components are intermediary complexes depending on partial saturation with hæmoglobin

Uppsala **Lars Beckman**

CONTROL OF ANTICOAGULANT THERAPY

Sir,—In their evaluation of the new reagent, thrombotest, Dr Matthews and Dr Walker (Dec 26) estimate the cost of each test to work out at about 4*d* (p 1162) A direct approach to the Norwegian source of supply on the other hand yields a quotation at the widely disparate figure of 1*s* 8½*d* Such a price, if sustained, renders an otherwise quite admirable preparation uneconomical for general use

Dumfries and Galloway Royal Infirmary,
Dumfries J **Laurie**

TREATMENT OF INGUINAL HERNIA

Sir,—In their valuable though depressing article of Jan 16 Mr Shuttleworth and Mr Davies show that the Bloodgood operation gives good results, though the numbers are small. I assume, perhaps wrongly, that they mean the rectus-sheath flap technique first described by W S Halsted[1] and first used by him four years earlier Bloodgood's own remarks[2] were, "Later Halsted modified the transplantation of the muscle by turning down a pedunculated flap of the anterior sheath of the rectus"

In 1952 I followed up 78 inguinal herniæ in 68 patients All operations had been carried out by me, using the rectus-sheath flap technique, and all follow-ups involved personal examination by myself at intervals varying from $2^1/_2$ to 11 years The ages of the patients lay between 26 and 74 years There were 5 recurrences, a recurrence-rate of 6 4%, this includes 1 patient whose original site was sound but who had a bulge at the margin of the rectus muscle and another whose original site was sound but who had a femoral hernia on that side when seen 10 years later There was 1 recurrence among 10 bilateral herniæ, this was at the site of operation for a recurrent hernia following an operation 18 years earlier There were no recurrences among 20 direct herniæ.

Dissatisfied with a recurrence-rate of 6 4% and impressed by Tanner's description of the rectus-sheath slide technique, I abandoned the so-called Bloodgood method some years ago, but the St Thomas's figures

Leicester DONALD MCGAVIN

INCUBATION PERIOD OF CUTANEOUS LEISHMANIASIS

SIR,—In his valuable article on Jan 16, Professor Symmers refers to the variable and sometimes prolonged incubation period of cutaneous leishmaniasis (oriental sore)

Perhaps I may be allowed to emphasise this point by mentioning that an interval as long as four years and seven months has been reported as elapsing between experimental human inoculation and the appearance of the lesion,[1] and that naturally occurring cases with circumstantial incubation periods of five [2] and even ten years [3] have been recorded

PRENATAL ORIGIN OF THE RESPIRATORY DISTRESS (HYALINE-MEMBRANE) SYNDROME OF PREMATURE INFANTS

SIR,—Attention has been drawn to the presence of a substance, probably a mucoprotein in the lungs, which greatly reduces surface tension when the area lined by it is reduced during expiration [4] This prevents excessive collapse of the lungs before the beginning of the following inspiration, and thus promotes stability of lung expansion A significant reduction of this activity is found regularly, though not exclusively, in the lungs of newborn infants dying with the respiratory distress syndrome (sometimes called hyaline-membrane syndrome) [5] This makes available for the first time a tool for the systematic and objective study of at least some of the aspects of this puzzling condition

The following observations were made on a group of stillborn infants who had not lived to show either the clinical signs or the pathological changes characteristic of the syndrome

They were among 120 perinatal deaths in which static pressure-volume curves were obtained from lung specimens Air was introduced at pressure increments of 2 to 5 cm of water up to 30 cm, and further increments of 5 to 10 cm, usually up to a point where further increase did not significantly enlarge the lung volume Pressure was then decreased by similar steps Each experiment took from 15 to 30 minutes, and was repeated at least once In about one-third of the cases lung extract was subsequently examined by means of a variable-area surface balance by Clements and coworkers, there was good correlation of surface-tension data with the stability of lung expansion [6]

For the purpose of greater ease of evaluation of the stability of expansion, a method was devised which characterises the shape of the deflation curve between 10 and 0 cm of water pressure by the area between it and the abscissa, in relation to the level of maximal expansion A high figure denotes good stability, most values ranged below 1 2 A description of the calculation, and detailed evaluation of all results in stillborn and liveborn infants, will be reported elsewhere

The lungs of most infants dying with the respiratory distress syndrome showed poor stability, which is in agreement with Avery and Mead [5] The question now arises whether the deficiency in surface activity observed in the respiratory distress syndrome is present at birth, or arises after birth under the influence of the early stages of the syndrome or a predisposing condition In other words, one wonders whether a newborn infant may be destined or predisposed to develop the respiratory distress syndrome before taking its first breath

STABILITY OF LUNG EXPANSION OF 38 STILLBORN INFANTS

Stability figure	Body-weight							Total
	Up to 500 g	501–1000 g	1001–1500 g	1501–2000 g	2001–2500 g	2501–3000 g	Over 3000 g	
0 00–0 10	—	1	1	—	—	—	—	2
0 11–0 20	—	—	—	—	—	—	—	0
0 21–0 30	—	3	—	1	—	—	—	4
0 31–0 40	—	1	—	1	—	—	—	2
0 41–0 50	—	2	1	—	—	2	—	5
0 51–0 60	1	—	1	—	—	—	—	2
0 61–0 70	—	—	—	—	—	1	—	1
0 71–0 80	—	—	—	—	—	—	—	0
0 81–0 90	—	1	—	—	1	1	1	4
0 91–1 00	—	2	—	—	2	—	2	6
1 01–1 10	1	—	1	1	—	—	1	4
1 11–1 20	—	—	—	2	2	1	—	5
1 21–1 30	—	1	—	—	—	1	—	2
Over 1 30	—	1	—	—	—	—	—	1

The accompanying table shows the stability of lung expansion for all 38 stillborn infants within the present material It is apparent that the values are not uniformly distributed, but form a low-stability group below 0 7 (16 cases) and a high stability group above 0 8 (22 cases), each with its own peak. No values between 0 7 and 0 8 were observed Poor stability occurs frequently but not uniformly in the very immature, it was not found in infants weighing more than 3000 g The incidence of low stability in relation to birthweight appears to follow approximately the trend of occurrence of the respiratory distress syndrome Microscopic examination of the stillborn material showed no difference between those with low and those with high stability

Differences in the stability of lung expansion therefore exist in infants who have never breathed This suggests that an infant may be predisposed to the respiratory distress syndrome while in utero We do not know whether infants born with good stability can, as a result of some disease process, yet develop the syndrome The present evidence suggests, however, that at least some of the causative factors should be looked for in the intra-uterine environment or in the intrinsic constitution of the fœtus It is interesting to note that the latter possibility has been suggested by Lieberman [7] on the basis of absence of the activity of the plasminogen activator

This work was aided by a grant from the United Cerebral Palsy Research and Educational Foundation

EMERGENCY RESUSCITATION IN RUPTURED ECTOPIC GESTATION

SIR,—For those who work in hospitals without facilities for blood-transfusion, autotransfusion can be a life-saving measure as your correspondents have confirmed I learnt this the hard way in the 'thirties when in Hong Kong where ectopic gestation was a common disease It still is in many parts of the world where blood-transfusion services do not exist In an article [8] entitled "Aids in the diagnosis and treatment of ectopic gestation" I emphasised the value and ease of autotransfusion The "citrate" method was used and the blood, provided it was not infected, scooped out of the abdomen with a galley-pot and filtered through 6 layers of fine gauze By this means, not only were lives saved but convalescence was much more rapid

Obituary

ERIC HENRY RHYS HARRIES

M.D Lond, F R.C.P, D P H.

As medical superintendent of fever hospitals in Birmingham and London during the 'twenties and 'thirties, Dr E H R Harries did his most important work when the acute infectious diseases were prevalent and had a heavy mortality An expert in diagnosis and treatment, he was also a pioneer in administrative and technical methods of control He died on Jan 12 on his 78th birthday

He qualified from the London Hospital in 1906, and after holding the post of R.M O at Tite Street Hospital for Children, Chelsea, he entered the fever service as a medical officer at Fazakerley Hospital in Liverpool He left to take up a post as tuberculosis officer under the Welsh National Memorial Association at Newport, Monmouthshire During the 1914–18 war he served with the R.A.M.C in Mesopotamia In 1920 he became medical superintendent of the Birmingham Fever Hospital.

At Birmingham he realised the potentialities of immunisation, and he was an early advocate of immunising all children against diphtheria and nurses against scarlet fever and diphtheria This work attracted the attention of Dr J A. H Brincker, then in charge of the London County Council fever hospitals, and in 1931 Harries was appointed superintendent of the North Eastern Fever Hospital (now St. Ann's General Hospital, Tottenham) It had 661 beds and was the largest fever hospital in constant use in the L C C service. Harries quickly gave the North Eastern the facilities of a general hospital He introduced radiology, and in those days, when mastoids were one of the worst complications of scarlet fever, radiology was a valuable guide to treatment. He also encouraged the use of electrocardiography in his diphtheria wards Though he was a pioneer of immunisation against scarlet fever he realised its imperfections and welcomed wholeheartedly sulphonamides, and later penicillin, as well as an efficient streptococcal antitoxin, as means of reducing the stay of children in hospitals He was particularly interested in mechanical measures to alleviate diphtheritic tracheitis

His Milroy lectures to the Royal College of Physicians in 1935 were a masterly analysis of current practice in the control of infection in children's wards and the dangers of cross-infection. At a time when complications were rife he tried to lessen them by bed isolation, limitation of visitors, masking of patients, treatment of carriers, passive immunisation of patients (especially against measles), and active immunisation of nurses In his pioneer work in 1933 on scarlet fever he showed that active immunisation did not increase the number of carriers All these methods improved the lot of children, but, as he once said, " no degree of architectural skill, no medical administrative measures, and no elaboration of technique can prevent entirely the transference of infection by human agencies The best laid schemes may fail unless in addition the personnel is numerically and technically adequate to cope with the special dangers of infection which must inevitably attend the aggregation of children in hospitals "

Harries in due course succeeded Dr A F Cameron as chief medical superintendent of the fever hospitals of the L C C and he took a prominent part in designing a new type of ward block for the reconstruction of his hospital He retired in 1947

At Birmingham he had been the lecturer in infectious diseases, and in London students from the Middlesex and Royal Free Hospitals attended his courses His book, *Clinical Practice in Infectious Diseases*, written with the late Maurice Mitman, was first published in 1940 at a time when the control of infectious diseases was of national interest The orderly arrangement, lucid writing, and good sense shown in this work were also evident in his counsel as a consultant adviser to this journal

A D writes

" Harries had a quick and original mind and the uncanny knack of exposing the core of a complex problem with lightning speed. He was tall and thin. He took life seriously and was renowned for his caustic wit it was woe betide any junior at his hospital who became slack. Apart from a liking for music, he made his work and his patients his hobby and had no other He was an omnivorous reader—a taste which he was able to indulge after his retirement."

Dr Harries was president of the Medical Officers of Schools Association in 1938–39 Of his work there R E S writes

" He kept abreast of progress and was always willing to help with his experience. He spent many hours helping us to revise our code of rules as well as presiding at our meetings He was always ready to advise members who wished to immunise schoolboys and he always pointed out the snags as well as the advantages No pressure would ever make him accept a fee he said simply that he was full-time He usually looked in a hurry and frail, but he always found time to do the things he thought were worth while "

Dr Harries leaves a widow and two children His son is neurosurgeon to University College Hospital

ISABEL EMSLIE HUTTON

C.B E, M D Edin

Lady Hutton, emeritus consultant psychiatrist to the British Hospital for Functional Nervous Disorders and the author of several well-known books on health education, died at her London home on Jan 11

She was the only daughter of James Emslie, deputy keeper of the Privy Seal of Scotland, and she was educated at Edinburgh Ladies' College and the University of Edinburgh, where she qualified in 1910 After postgraduate study in Vienna and Munich, in 1912 she took her M D with honours in psychological medicine and later held appointments as pathologist at Stirling District Mental Hospital and the Royal Mental Hospital in Edinburgh. During the 1914–18 war she served with the Scottish Women's hospitals in Macedonia and Serbia and the Lady Muriel Paget Hospital at Sebastopol For her work she was awarded the Serbian orders of the White Eagle and St Sava, the French Croix de Guerre, and the Order of St Anne of Russia After the war she returned to her Edinburgh appointment, but she resigned it on her marriage in 1921 and settled in consultant practice in London She was appointed to the staff of the West End Hospital for Nervous Diseases and the British Hospital for Functional Mental and Nervous Disorders, where she held outpatient clinics for early mental cases This work led her to write her book on *Mental Disease in Modern Life* Her experience with outpatients also led her to write *The Hygiene of Marriage*, first published in 1923, which ran into nine editions In 1958 she published *Woman's Change of Life*

In 1938 Dr Hutton moved to India, where her husband held an appointment at Quetta During the late war she was director of the Indian Red Cross Welfare Service, and she held this post until 1946 when she returned to this country and resumed her practice in London She was appointed C B.E in 1948

L F writes

" Isabel Emslie as a girl must be a still vivid memory to many of her contemporaries at Edinburgh University for her spontaneous charm and gay courage All medical women in those days had to face a rough passage, worse after they qualified, and Isabel Emslie had just the necessary qualifications for this sort of pioneering Her sunny good looks and good temper smoothed away many of the initial difficulties, and she steadily refused to let the most obstinate prejudice get her down Such opportunities as came she made the most of The basis of her professional work was a great desire to help other people in trouble, especially those who tended then to be neglected, and it was this driving force that impelled her to take up psychiatry and apply her experience for the benefit of women in neurotic difficulties In both world wars Lady Hutton's gifts of initiative and organisation found full scope, first in the Balkans and later in India In the end she remained a gracious, sympathetic, stimulating personality, loved and admired by a wide circle "

Lady Hutton is survived by her husband, Lieut-General Sir Thomas Hutton

---

Public Health

Scattered Cyanide

LATE at night on Monday, Jan 11, three containers of potassium-cyanide powder fell into the roadway at Ashby Parva, in Leicestershire, from a haulage contractor's lorry travelling northwards to Leire One of the containers was broken open and about 25 lb of its contents spilled into the highway The police and fire brigade were called and the undamaged and open containers removed The powder on the highway was hosed away into roadside gullies and through the farmyard of Long Acre Farm adjoining the highway in Ashby Parva The effect of hosing the powder from the highway was to convey a toxic solution into gullies, which discharge into open ditches and thence into watercourses, and on to the surface of the highway, the farmyard, and the adjacent field Accordingly, all householders in the affected area were warned not to use well water and to withdraw cattle and stock from the open fields

Meanwhile, a representative of Imperial Chemical Industries Ltd, acting for the manufacturers of the powder, had arranged for the supply of a strong neutralising agent and this was applied in the early afternoon of Jan 12 to the gullies, highway, farmyard, and field From the chemical reaction obtained it was obvious that this treatment was effective, but there could be no assurance that all the toxic liquid was reached, and in fact samples taken from the farmyard and field in the late afternoon of Jan 12 showed traces of the poison. Samples taken earlier from five wells showed no trace A further application of the neutralising agent was made on Jan 13

There was a blocked road gulley in Ashby Parva, and arrangements were being made for this to be released under control and washed out with neutraliser Meanwhile tests continued to be taken at all points to which it seems possible that the poison could travel

All affected authorities and public utility undertakers were informed, and the Trent River Board gave considerable assistance in the field analysis of samples The Ministry of Housing and Local Government sent a senior engineer and a chemist to advise on any further steps which might be taken

It will not be possible for some two or three weeks to say with certainty that there is no danger to public health, but during this time the inhabitants of the area affected or likely to be affected will be told not to drink from private wells and to keep cattle and stock away from ditches and watercourses It is hoped that this action will cause only minor inconvenience, since there is a public supply of piped water throughout the area

We are indebted to Dr A C Ross, medical officer of health, Blaby Rural District Council, and to the Clerk of Lutterworth Rural District Council for supplying this information

Notes and News

EXCHANGES BETWEEN RUSSIA AND THE UNITED STATES

ONE of the most welcome breaches in the Iron Curtain, agreed in principle during Mr Krushchev's visit to the United States in September, is the exchange agreement between the United States and the Soviet Union its medical section includes plans for cooperation in the next two years The programme wisely provides not only for exchanges at Ministry level (between the Soviet Ministry of Health and the U S Public Health Service) but also between specific research institutes and individual workers It also provides that the Governments should facilitate publication of articles by workers of each nation in the journals of the other and increased exchange of medical journals, books, and films

More specifically, cooperation is planned in research on cancer (between the Soviet Institute of Experimental and Clinical Oncology and the American National Cancer Institute and Sloan-Kettering Institute), on cardiovascular disease (between the Soviet Institute of Therapy and the American National Heart Institute and, through them, other bodies), and on poliomyelitis (between the Soviet Institute for the Study of Poliomyelitis and, in America, the Research Foundation of the Children's Hospital in Cincinnati, where Dr Albert Sabin has his laboratory, and the National Institutes of Health) The bodies concerned will give each other information about past research and future plans, exchange specialists, organise joint studies, and take part in annual meetings alternately in the United States and the Soviet Union This year the studies on poliomyelitis will concentrate on the Soviet use of the Sabin live-virus vaccine, and the meeting will be held in the Soviet Union, the meetings on cardiovascular and malignant disease will be held in the United States

Other exchanges planned are of parties of up to 20 senior and junior research-workers for periods of up to a year to learn about the work of scientific establishments in the other country, to exchange experience, and to conduct joint research, and of smaller delegations for a few weeks to study specific subjects Soviet delegates in the United States will study neoplasms, especially biochemical and histochemical research, cardiovascular pathology, especially hypertension and ischæmic diseases, cardiac surgery and methods of artificial circulation, virus genetics, and industrial hygiene, especially silicosis, industrial toxicology, and the physiology of labour American delegates will study microbiology, neurophysiology and neuropathology, metabolism and genetics, medical ecology, and maternal and child care, especially any data that can be added to the U S Public Health Service study of 40,000 mothers and their children before and six years after birth for factors influencing congenital defects[1]

TEACHING NUTRITION

THE major nutritional diseases are fortunately now rare in most countries of Europe, but few doctors could claim that they have no worries about the state of nutrition of some of their patients Some kind of governmental food policy, backed by the best advice, is needed in even the richest countries In democratic countries, since national policies tend to follow public opinion, it is obviously important that everyone should understand about food and know what is needed this requires teaching, or even preaching, and the medical profession has an important part to play

In December W H.O and F.A O held at Bad Homburg, near Frankfurt, a joint symposium on Education and Training in Nutrition in Europe Perhaps the most interesting proposals concerned teaching in medical schools

> " It was made clear that the training of medical students in nutrition is inadequate in many medical schools Although many of the basic and clinical aspects are taught, there is a lack of integration between the various disciplines, moreover, the subject is not taught as a practical subject related to everyday problems of family life In order to remedy this, one person could with advantage be made responsible for the co-ordination of all aspects of nutrition teaching at all stages of the medical student's career He should be a person who has a comprehensive and practical knowledge of nutrition ".

One proposal was that the necessary coordination could be achieved by the establishment of a " nutrition unit ", attached to an existing department and staffed by members specially interested in nutrition who should have facilities for laboratory and field research and also for teaching

The report of the symposium, to be published in French and English, will also deal with the education in nutrition of public-health officers, medical postgraduates, nurses, dietitians, nutritionists, home economists, agronomists, and schoolteachers

University of Cambridge

On Dec. 22 the degree of B CHIR. was conferred on the following

C L C Arnold, N A Atalla, N J Barton, J P Blackburn, David Bond, F M Boston, K R Bowles, E. G Cantrell, A F S Childs, R B Church, D R F Clark, T T Davies, J B Douglas, G H Evans, E W L Fletcher, C du Ve Florey, D M C Forster, H B Francis, F R Gamman, N F C Gane, David Godwin, John Gough, S G I Hamilton, Simon Harcourt-Webster, Alexander Harley, T S Hattersley, J M Henk, Pamela M Hill, Peter Hill, G A Hobbs, G R Hobday, S M N Jaikaran, E V Jones, R S Kirk, J E R Lart, Beng Kwan Lee, R A Lewin, P W Lord, J E D MacLaren, J H MacMillan, D M Marsh, N J Maurice-Smith, C S Menzies-Kitchin, R H Morgan, D N E Myers, M J Orrell, Margaret E Peppercorn, J N Powell, D A Richards, E. H Richards, Shirley J Richmond, J R L. Roberts, A P Sherman, R I R Sinton, N J Strickland, Michael Thomas, P G R Tingley, Keith Whittle, J S Wrigglesworth

University of Bristol

At recent examinations for the degree of M D the following were successful

T J Butler (with distinction), C C Downie, J E Tovey

University of Sheffield

A course in dermatology for general practitioners will be held on April 4–8 at the Rupert Hallam Department of Dermatology, Sheffield Royal Infirmary Further details may be found in our advertisement columns

University of St Andrews

On Jan 8 the following degrees were conferred

M B , Ch B—Mary R Bestow, Catherine D Campbell, B C Davies, Doreen Wilson or Eldred, A M Gough, S W Gray, A B A Grubb, James Lawless, *G A Nimberg, R C Waters, Assefa Woldesemait

Ph.D in the faculty of medicine—* Deva Nandan Sharma

* In absentia

University of Glasgow

On Jan. 16 the following degrees were conferred

M.D—E McC McGirr, R. G Sommerville (with honours), A P Curran, Robert Rankine, Morag C Timbury (with commendation)

Ph.D—G C Arneil

Ch.M—D W Short.

M.B , Ch.B—J G Bisset, J T Breen, J M Carlisle, T A H Hide, E J N Hoisington, James Kelly, Alexander King, J L. Kydd, Charles Lynch, Margaret M McNamara, G L Miller, G A. Montgomerie, John Newlands, T P Orr, Patrick Palmer, W H Pitt, Thomas Prior, G D Ross, Lingasphara Lutchmana Venkatasawny, Jean M West, Hannchen D Wirth

Order of St. John of Jerusalem

The Queen has sanctioned the following promotions in, and appointments to, this order

As Knights—William Bain, M.B , Brigadier Sir Kenneth Fraser, C.B.E , E.D , M.B , F.R.A.C.S , R S Steel, O.B.E , M.B , M.R.C.P , F.R.A.C.P , Major-General Sir Frank Norris, K.B.E., C.B , D.S O , E.D , M.D , B C. Cohen, M.B , Brigadier A L Dawkins, O.B.E., E.D , F.R C.S , A.A.M C.

As Dame—Mary A C Ainscow, M.B

As Commanders (Brothers)—P S Pringle, M.R.C.S., Air Commodore John Magner, M.D , E L. Butler, M.B , W L Stewart, M.B K M. Macdonald, M B , Robert Rutherford M.B , T.D , W R. Cambridge, M.R C.S , Lieut.-Colonel E J Selby, O.B.E., M.R.C.S , S G Nelson, M.B , F.R C.P , F L. Firkin, M.B , Major Brooke Moore, M.B , F.R.C.S , Lieut -Colonel George Gregg, O.B E , M.D , F.R C.P

As Officers—A J Amor, C.B.E., M.D , J W McK Nicholl, M.D , D I Acres, M.R C.S., Wing-Commander H W Whittingham, M.B., K G Bergin, M.D , J L Temple, M B , F.R C.S , W H Dunn, M.R.C.S , Sukha Sagar Datta, M D , Alexander Burns, O.B.E , M C., M.B , D K Gaitskell, M.R.C.S , Surgeon Commander H M Darlow, M.R C.S., R.N , Salvino Caruana, M.D , H G Vyse, O.B E , M.R C.S , J S McLintock, M.B , M A. Byer, O.B.E , M.B , C. D Bateman, M.B , Henry Gordon Prest, M.B , L D Hodby, M.B , A. N Jacobs, M.B , Elizabeth M Anderson, M.D , Mary E Rolston, M.B

Royal Society

An award under the society's and Nuffield Foundation's Commonwealth bursaries scheme has been made to Dr J C Gould, senior lecturer in bacteriology, University of Edinburgh

Royal College of Surgeons of England

At a meeting of the council on Jan 14, with Sir James Paterson Ross, the president, in the chair, Mr L J Williams was admitted to the court of patrons Prof A W Wilkinson was admitted to the fellowship *ad eundem*

Mr H J Seddon was appointed Robert Jones lecturer, and a Moynihan lectureship was awarded to Prof Fernand Orban and a college lecture to Mr Douglas Robb (Commonwealth travelling professor) Dr R P W Shackleton was appointed Frederic Hewitt lecturer for 1961

The following diplomas were granted jointly with the Royal College of Physicians

D L O—Unus Omar Ali, Soroj Kanto Ally, G P E Beaney, Leslie Bernstein, P R Blenkinsop, D J Durcan, Muriel E Gibb, Sujit Kumar Guha, D G Jones, J G Kourris, Ram Partap Kumar, G J Little, R S McAlary, W J O Connell, Iraj Parhizgar, A S Shalom, O T Taylor, C I Woolf

Postgraduate Medical School of London

A symposium on recent advances in knowledge of the anæmias will be held for consultants on March 25 and 26, and not on April 7 and 8 as previously announced Further particulars will be found in our advertisement columns

Preventive and Clinical Medicine for Older People

The Society of Medical Officers of Health and the British Geriatrics Society are holding a conference on this subject from March 31 to April 2 in Bristol Further particulars may be had from the secretary of the Society of Medical Officers of Health, Tavistock House South, London, W C 1

New M R C Units

The Medical Research Council have lately set up a blood coagulation research unit, by agreement with the United Oxford Hospitals, at the Churchill Hospital, Oxford, under the part-time direction of Dr R G Macfarlane, and an environmental radiation research group under the honorary direction of Prof F W Spiers in the department of medical physics, University of Leeds

Griseofulvin Symposium

A symposium on the oral treatment of fungus infections will be held at 1, Wimpole Street, London, W 1, on Friday and Saturday, May 13 and 14 Particulars may be had from the symposium secretary, St John's Hospital Dermatological Society, St John's Hospital, Lisle Street, W C 2

Royal Society of Health

The annual congress of this society will be held at Torquay from April 25 to 28 under the presidency of Lord Morrison of Lambeth For the first time there will be a section of the executive councils' services, of which Dr R W Rae will be president Other sections will include health education (president, Dr Doris Odlum), medical officers of health (Dr J Stevenson Logan), preventive medicine (Dr G S Wilson), mental health (Prof G R Hargreaves), family health and welfare (Prof A B Semple), and hospitals (Dr G E Godber) Further particulars may be had from the press officer of the society, 90, Buckingham Palace Road, London, S W 1

Medical Art Society

This society's exhibition will be held from March 4 to 17 at Walker's Galleries, New Bond Street, London, W 1

The *Journal of the Faculty of Radiologists* is to change its title to *Clinical Radiology, The Journal of the Faculty of Radiologists* as from the January issue (vol 11, no 1) The change in title is accompanied by changes in cover design, typescript, and format, and the journal will now be published by Messrs E & S Livingstone Ltd, of Edinburgh

The Sheffield University Medical Society's annual dinner will be held on Thursday, Feb 4, at 8 P M in the Firth Hall of the university The principal guest and speaker will be Mr A Dickson Wright Tickets (members 18*s* 6*d*, patrons 22*s*, non-members 25*s*) may be had from the dinner secretary at the university

A semipermanent exhibition on clinical effects of griseofulvin, arranged by Dr Brian Russell and Dr C J Stevenson, will be held at the Institute of Dermatology, Lisle Street, London, W C 2, from Feb 3 to 26

Appointments

ASHLEY, J B, M D Lpool consultant pathologist, Glantawe H M C. area

CHAMBERS, ROBERT, M B Durh, D P M assistant psychiatrist (S H M O), Horton Road and Coney Hill group of hospitals, Gloucester

CORBITT, F H, M R C S, D P M psychiatrist in mental deficiency, Greaves Hall Hospital, Southport

GOUGH, M H, M B Lond, F R C S part-time surgical outpatient assistant, The Hospital for Sick Children, Great Ormond Street, London

HINGSTON, C. W J, M R C S, D P H, D T M & H assistant M O (school health and child-welfare services), Worcestershire

JONES, D H, M R C S, D P M consultant psychiatrist and medical superintendent, Deva Hospital, Chester

LUNT, R L, M B Manc, M R C O G part-time consultant obstetrician and gynæcologist, City General Hospital, Sheffield

McCARTHY, T F, M D, B SC Wales, M.R C P consultant geriatrician, Glantawe H M C area

MACVICAR, DONALD, M D Edin, M R C O G part-time consultant obstetrician and gynæcologist Royal Infirmary, associated maternity hospitals, and General Hospital, Leicester

SPENCER, R W, M B Birm, M R C P consultant pathologist, West Cornwall clinical area

WATSON, W S, M D Edin, F R C P E, D P M consultant neurologist, department of surgical neurology, Western General Hospital and Royal Infirmary, Edinburgh

Newcastle Regional Hospital Board

DAVIES, G L., M R C S, D P M consultant psychiatrist in child guidance, St Luke's Hospital, Middlesbrough

DUNCAN, G D, M B Aberd, D P H deputy S A M O to the Board

MURRAY, FRANCIS, M R C S, D P M assistant psychiatrist (S H.M O), Prudhoe and Monkton Hospital

VAITHLINGHAM, P S, F R C S senior casualty officer, Sunderland group of hospitals

From the Common Cold Research Unit (Medical Research Council), Salisbury, Wilts

Work on the common cold is hampered because it has not been possible to detect or propagate the causative virus or viruses except by inoculation of human volunteers or chimpanzees In this and the following papers we describe some properties of the cold viruses under study at this unit, and evidence for their transmission in vitro The first paper lays particular emphasis on experiments employing human volunteers and the second and third on some laboratory studies It should, however, be made clear that the various lines of work have been artificially separated and were actually carried on in parallel

Clinical Methods

Volunteers were isolated and observed at this unit by the methods previously described (Andrewes 1949, Roden 1958) They were isolated for 4 days before administration of the inoculum and were observed for 5 days after inoculation The inoculum of 1 ml, diluted if necessary in Hanks' saline, was administered as drops up the nostrils Assessments were made by a clinical observer unaware of the nature of the material under test.

Laboratory Methods

Tissue-culture Techniques

Human embryos from therapeutic hysterotomies performed between 3 and 5 months of gestation were dissected aseptically at the Royal Marsden Hospital The kidneys and lungs were placed in a sterile bottle immersed in broken ice and sent to this unit by train The renal cortex and medulla were chopped with sharp scalpels into pieces about 1 mm. across and placed in Hanks' saline The tissue was washed and the cells were dispersed by treatment with 0·25% 'Difco' trypsin in Hanks' saline at 37 C and a pH of about 7 4 The cell suspension was removed and added to 5 ml horse serum and the process repeated. The cells were spun down and resuspended in medium to give a final dilution of 1 100 to 1 500 The medium consisted of 5% or 10% calf serum and 0 5% lactalbumin hydrolysate in Hanks saline containing 0 03% sodium bicarbonate and 100 units penicillin, 100 μg streptomycin, and 20 units of nystatin (mycostatin) per ml 1 ml was added to culture tubes closed with silicone bungs The tubes were incubated at 37°C without rotation and the medium was renewed every 2 or 3 days until a cell sheet was formed, this usually took about 5 days

Human embryo lung cultures were prepared in the same way Human thyroid cultures were prepared as described by Pulvertaft et al (1959), calf kidney cultures and monkey kidney cultures as described elsewhere (Negroni and Tyrrell 1959) When ready for use, the cultures were washed with Hanks saline and 1 5 ml of medium 199 with the antibiotics mentioned above was added 0 2 ml of inoculum was then added, and the cultures were placed in a roller drum

The medium was usually changed 1 day after inoculation and at intervals of 4 days thereafter if necessary Incubation at this stage was either at 33° or 36 C

In early experiments it was thought that cold virus in the fluids from cultures maintained in medium 199 was losing its activity on storage or after repeated freezing and thawing, thereafter 0 5% of bovine plasma-albumin, fraction V (B P A.),* was added to culture fluids before storage in the dry-ice refrigerator, and specimens were frozen and thawed only once

The Virus Strains

From adults, not in isolation, with typical common colds, nasal washings were taken, using either 10% broth saline or Hanks' saline containing 0 5% bovine plasma-albumin, 100 units of penicillin and 100 μg of streptomycin per ml were added. The washings were shaken with glass beads and centrifuged at about 2000 r p m for 10 minutes After 1/10 dilution in broth saline or Hanks' saline they produced typical colds when inoculated into volunteers

To exclude the presence of known viruses the washings were then introduced into tissue cultures—in early experiments HeLa cell and human embryo lung cultures were used. Later we turned to cultures of human embryo kidney and monkey kidney cells maintained in medium 199 and tested for hæmadsorption (Vogel and Shelokov 1957) Several passages were made and the total period of observation was several weeks We found no evidence of the presence of known enteroviruses, adenoviruses, or the parainfluenza (hæmadsorption) viruses recently isolated from persons with respiratory diseases (see reviews by Huebner et al. 1958 and Andrewes 1959) Washings were stored in a dry-ice refrigerator at about −50 C and thawed immediately before use

Results

Properties of the Viruses

We made a few observations on properties of the agent producing colds in volunteers, for reasons which will become apparent later in this series

(a) Ether Resistance

Washings were mixed with from 10 to 20% by volume of diethyl ether and held at 4°C overnight. The ether was then removed and the washings were inoculated into groups of volunteers Control material was prepared in the same way without addition of ether The virus apparently survived ether treatment in 5 of the 6 washings tested. In the case of the P K pool of washings, 5 of 14 volunteers inoculated with ether-treated material developed colds while 6 of 14 inoculated with untreated material did so With H G P washings, the corresponding figures were 1 of 6 and 1 of 5

(b) Acid Resistance

A washing containing strain H G.P was dialysed at 4°C for 3 hours against 0 1 *M* citrate buffer pH 2 1, the buffer was then removed by dialysis against saline None of 7 volunteers who received this material developed colds, although 2 of 8 volunteers who received untreated material did so

(c) Neutralisation by Human Serum

The strain of H G P was used for experiments to determine whether a virus of this type could be neutralised by immune

TABLE I—NEUTRALISATION IN VITRO OF COMMON COLD VIRUS (STRAIN H G P)

—	No of colds in volunteers receiving washing mixed with				
	Broth saline	Acute phase serum*	Convalescent serum*	Bovine plasma albumin	Human γ-globulin
Experiment I	3 8†	2 10	1/10		
Experiment II	3 9			3 10	0/18

* The sera were obtained from subject H.G.P at the time the washings were taken and 16 days later

† Numerator = no of colds Denominator = number of volunteers inoculated.

---

* Supplied by Armour Laboratories, Hampden Park, Eastbourne, England.

7118

serum Acute and convalescent phase sera from the donor of the washings were heated at 56°C for 30 minutes, diluted 1 in 10, and mixed with an equal volume of washings diluted 1/5 The mixtures were held at room-temperature for about 2 hours before inoculation to volunteers In a second experiment the washings were mixed with an equal volume of a solution of Lister Institute human γ-globulin 10 mg per ml and held at 4°C overnight and then at room temperature for 2 hours A control containing bovine plasma-albumin was also used The results are shown in table I The serum did not neutralise the virus but the γ-globulin apparently did so Since the bovine albumin did not neutralise, it is probable that the effect of the γ-globulin was due to its content of antibodies The results and conclusions are similar to those of Jackson et al (1958)

Propagation of Virus Early Attempts

Andrewes et al (1953) reported an apparently successful attempt to transmit a common cold strain (D C) in roller-tube cultures of human embryo lung maintained in Enders' medium However, no colds were produced with material beyond the tenth passage and numerous attempts over 2 years to repeat the experiments were unsuccessful (Pereira and Roden, unpublished experiments) It seemed that some technical modification might hold the key to success Accordingly the method of organ culture was used No success was obtained using human embryonic œsophagus, skin, nasal epithelium, or intestine There was rather more promise with fragments of embryonic human trachea (see Bang and Niven 1958) A few colds did occur in volunteers inoculated with the first passage in such cultures The results were, however, irregular, colds could not be produced with material from passages beyond the first and it seems possible that the few colds were caused by virus surviving from the inoculum

Further experiments with roller-tube cultures of monkey kidney were then carried out We tried medium 199, Enders' medium (5% horse serum, 5% beef embryo extract, and 90% bovine amniotic fluid), and 0 1% yeast extract with 0 5% lactalbumin hydrolysate in Hanks' saline, and we varied the interval between passing Colds *occurred infrequently and irregularly in volunteers receiving* material from any of these cultures

An attempt was next made to repeat the experiment using human embryo kidney cultures Because of shortage of materials only medium 199 was used and the experiment had to be discontinued as the cultures began to disintegrate after 10 days in this medium Nevertheless material from these cultures produced colds in volunteers more frequently and the matter was therefore systematically investigated, as described below

TABLE II—COLDS PRODUCED BY INOCULATION OF VOLUNTEERS WITH FLUIDS FROM CULTURES MAINTAINED IN *MEDIUM 199* WITHOUT SUPPLEMENTS

—			No of colds in volunteers receiving			
			Test fluid	*Control fluids*		
Strain	Passage	Temperature (°C)	Inoculated human cultures	Uninoculated human cultures	Inoculated calf cultures	Inoculated tubes without cells
P K	1	33 & 36*	4/9			0/8
P K	1	33	3/7			
P K	1	36	1/6			
P K	2	33	2/10			
P K	2	33	3/14	0/14		0/8
P K	4	33	0/7	0/5		
H G P	1	33 & 36*	2/9			0/8
H G P	2	33	1/8	0/5	0/7	
H G P	2	33	5/16	0/8	0/8	
H G P	4	33	1/16	0/7		

* A mixture of fluids from cultures maintained at each temperature

Results with Modified Technique

The experiments were planned to determine as clearly as possible the significance of the colds in volunteers receiving human embryo kidney culture material They might have appeared because the inoculum enhanced non specifically a hypothetical latent cold virus infection in the volunteers This possibility was controlled by giving volunteers uninoculated culture medium containing bovine plasma-albumin at the time at which other volunteers received the test material

We also tested the possibility that there might be a cold virus latent in the tissue cultures, volunteers were given fluids from a parallel series of passages made exactly as in the test series except that it was started with uninfected broth saline The third possibility was that the volunteers might be infected by virus carried over from the original washing, to test this we gave fluids from passage series made in culture tubes without cells or in cultures of calf kidney cells, we thought it unlikely that cold virus would grow in calf kidney cells, yet these might nevertheless preserve the virus At first these control materials were given separately, but in later experiments they were pooled

The results obtained have been summarised in table II They show that no colds developed in 78 volunteers who received control material of various sorts, whereas 22 colds developed in 102 who received fluids from cultures inoculated with cold washings The differences observed for second-passage fluids, when the most strictly controlled trials were made, are statistically significant (P between 0 05 and 0 01) Taken at their face value these results suggest that both the P K and H G P cold viruses were transmitted in culture for two passages Virus probably disappeared by the fourth passages, unless we postulate that it multiplied in a form avirulent for man

Attempts were made to repeat these experiments using different materials Human embryo lung cultures were inoculated with P K virus, and human thyroid cultures were inoculated with the H G P strain The D C strain of cold used previously (Andrewes et al 1953) was inoculated into human embryo kidney cultures No colds were produced when first- or second-passage fluids from these experiments were given to groups of about 8 volunteers (22 volunteers in all), nor did any colds result when two groups of 10 volunteers received second-pass material from human kidney cultures inoculated with each of two " wild " cold washings which had failed to produce colds when administered to volunteers

Variations in Technique of Passage in Human Embryo Kidney Cells

We attempted to improve the method of cultivation by repeating these experiments systematically, varying the conditions and testing pooled or individual culture fluids in volunteers The results were not statistically significant but seemed to indicate that transmission probably occurred better at 33°C than 36°C, on harvesting at 4 rather than 2 or 6 days, and on transferring either medium or cell extracts

In-vitro experiments (Hitchcock and Tyrrell 1960) suggested that the virus might more readily be transmitted when 0 2% of B P A , and an extra 0 1% of glucose were added to the maintenance medium We therefore made serial passages in culture maintained in this medium starting with second-pass fluids of strains of H G P and P.K which had produced colds in volunteers The third strain, F E B, was passed at first in medium 199 supplemented with glucose and then with B P.A. also In all cases the cultures were maintained at 33° in a roller drum, and passages were made at 5 days using the fluid phase only

Table III shows that volunteers inoculated with material from the third, fourth, and eighth tissue-culture passages developed colds, they were, however, infrequent in volunteers receiving H G.P and P K material Altogether 14 of 71 volunteers who received virus material developed colds, while 3 of 55 who received control material did so This difference is statistically significant ($P < \cdot 05$) and strongly suggests that something was being transmitted which could cause colds in man This conclusion is however mainly due to the results obtained with strain F.E.B material and it is possible that the other two strains became attenuated on passage. The significance of our findings is discussed at the end of the third paper in this series (Tyrrell and Parsons 1960)

TABLE III—COLDS PRODUCED BY INOCULATION OF VOLUNTEERS WITH FLUIDS FROM HUMAN EMBRYO KIDNEY CULTURES MAINTAINED AT 33°C IN MEDIUM 199 SUPPLEMENTED WITH BOVINE PLASMA ALBUMIN AND OR GLUCOSE

Strain	No of serial passages	No of colds in volunteers receiving		
		Test material	Control material	Saline
H.G.P	4 8	2 16 2 15	1 12 1 10	0 5
P.K.	8	1 10	1 11	
F.E.B	3 4 8	3 6 2 8 4 16	0 7 * 0 6	0 4

* 5 volunteers one of whom developed a cold, have been excluded because the inoculum given was found to be contaminated with Echo 11 virus.

Summary

We have studied nasal washings from adults with common colds The causative virus in 5 of 6 washings was not inactivated by ether treatment. One strain (H G.P) was tested further and found to be inactivated by human γ-globulin and by treatment at pH 2

Certain virus strains apparently survived 1 passage in organ cultures of human embryo trachea, others survived 2 but not 4 passages in roller-tube cultures of human embryo kidney maintained at 33° in medium 199 When, however this medium was supplemented with 0 2% bovine plasma-albumin and an additional 0 1% glucose, colds were produced in significant numbers by third, fourth, and eighth passage material.

SOME VIRUS ISOLATIONS FROM COMMON COLDS

II VIRUS INTERFERENCE IN TISSUE CULTURES

G Hitchcock
B.A Cantab

D A J Tyrrell
M.D Sheff M R C P

From the Common Cold Research Unit (Medical Research Council), Salisbury, Wilts

THE first paper in this series (Tyrrell et al 1960) described experiments in which it appeared that something capable of producing colds in volunteers was being transmitted in tissue cultures of human embryo kidney cells Clearly it would be of great value to be able to recognise an infected tissue culture without recourse to inoculation of volunteers We accordingly tested in many ways cultures of the second passage of the H G.P and P K strains in human embryo kidney cultures It was not possible to stain cells specifically using the fluorescent-antibody technique No cytological abnormalities were found in cells stained by usual techniques nor when they were stained for nucleic acids with acridine orange. No excessive loss of cell proteins into the medium was detected It appeared, however, that when cultures supposedly infected with one of these viruses were inoculated with a second virus, less of the second virus was produced than in control cultures This finding was used to develop the improved methods of cultivation mentioned in the latter part of the preceding paper

Methods

Cultures

Human embryo kidney cultures prepared as described by Tyrrell et al. (1960) were used throughout, unless otherwise stated Medium 199 was used for maintenance and cultures were incubated at 33°C with rolling

"*Cold viruses*" were those described previously

Challenge Viruses

The Sendai strain of parainfluenza virus type 1 (Andrewes et al 1959) was used as infected allantoic fluid. The usual inoculum was about 0 2 hæmagglutinating (H.A.) unit per culture

The U strain of Echo 11 virus (Philipson and Rosen 1959) was used as a pool of tissue-culture fluid. The usual inoculum was about 0 2 H.A. units or 1000 I D_{50} per culture.

Hæmagglutination was usually measured using 1% human red cells in phosphate-buffered saline at room temperature.

Demonstration of Interference

Groups of 5–10 tissue cultures were inoculated with virus or control material. 5 days later all or half the medium was removed and challenge virus was added in fresh medium. Incubation was continued for 2 or 3 days and on one or both of these days the hæmagglutinin titre of the medium of each culture was determined. The geometric means of these titres were calculated for each group A difference of 2 on $\log_2$ scale was regarded as significant on the basis of the statistical analysis of

TABLE I—EXAMPLE OF AN INTERFERENCE EFFECT IN CULTURES CHALLENGED WITH ECHO 11 VIRUS 5 DAYS AFTER RECEIVING COMMON COLD WASHINGS

Inoculum	H.A. titres of individual tubes	Log geometric mean H.A. titre	Interference index (by difference)
Washings of patient with cold 2 days after onset	6, 2, 2, 2, 0, 0 4, 2, 0, 2	0·95 (a)	2·6 (c−a)
Washings of same patient without cold	12 6 8 12, 8, 8, 8, 6, 4, 2	2 7 (b)	0·85 (c−b)
0·5% bovine plasma-albumin in Hanks saline	8, 8 16, 6, 32, 16, 16, 16 8, 8	3 55 (c)	

some representative experiments About the same mean titres were found in cultures primarily inoculated with saline, with medium from cultures which had not received cold viruses, or with washings from volunteers without colds Cultures inoculated with material derived from subjects with colds frequently gave a significantly reduced titre, and a typical experiment is shown in table I The difference between the log of the mean hæmagglutinin titre of a test group of cultures and that of a control group was calculated and called the interference index

Results

In the first experiments, washings containing H G P virus were added to cultures and medium from these cultures was transferred to further cultures These cultures were challenged and found to show interference, which was detected on challenge at 4 or 5 days but not at 2 or 8 days Interference was demonstrated when either Sendai or Echo 11 virus was used for challenge, but the latter gave more reproducible titres and therefore more significant differences in titre The differences seemed to be of about the same magnitude whichever virus was used Other hæmagglutinating viruses were tested but seemed less satisfactory Results were best read 2 or 3 days after adding the challenge virus, later on, the difference between the infected and control cultures was often much less striking

TABLE II—INTERFERENCE IN CULTURES INOCULATED WITH HUMAN NASAL WASHINGS

Source of washing	Interference index in cultures receiving washing collected	
	During cold	After cold
Subject

P P	−0 6	−0 1
D T	0 2	−0 3
Pooled washings from volunteers receiving		
H G P	*4 1*	0 6
D C	1 2	

* Para-influenza-1 virus used in this experiment, Echo 11 in all others Significant values of the interference index are shown in italics

Washings were taken from adults suffering from colds and again after they had recovered These were tested for the presence of virus by the interference method and the results are shown in table II No interference was detected in cultures receiving material obtained from volunteers who had recovered from their colds but interference was evident in cultures inoculated with material from 2 of 4 natural colds and from 1 of 2 groups of volunteers given experimental colds No interference was apparent in cultures given second or third passage H G P virus grown without bovine plasma-albumin (B P A) and glucose supplements, a finding in agreement with the results of inoculating volunteers (cf table II of preceding paper) Interference was also observed in cultures inoculated with 2 other pools of washings obtained from different volunteers inoculated with the H G P strain and with 2 other pools from volunteers receiving the P K strain

In an attempt to improve the sensitivity of the method the medium was supplemented with an additional 0 1% glucose and with 0 2% B P A (fraction V) during the period between inoculation of cold material and inoculation of the challenge virus Preliminary experiments suggested that both of these measures increased the amount of interference, one such experiment is shown in table III

Using these supplements, attempts were made to propagate serially the factor which was apparently interfering with multiplication of the challenge virus As

TABLE III—EFFECT OF ADDITIONS TO MEDIUM 199 IN THE DEVELOPMENT OF INTERFERENCE IN CULTURES INOCULATED WITH FLUIDS FROM CULTURES INOCULATED WITH WASHINGS CONTAINING H G P VIRUS

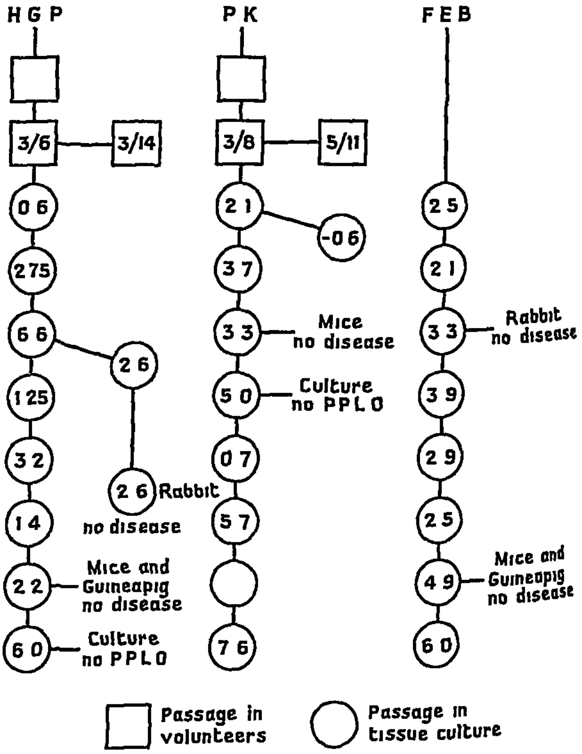
Final concentration (%) in medium of		Interference index*
Glucose	Bovine plasma-albumin	
0 1	0	−0 5
0 1	0 2	2 75
0 2	0	1 25

* Challenged with Echo 11 virus

starting material we used the two positive specimens referred to in table II (F E B and S W) and the two strains previously studied in volunteers (H G P and P K.) All but S W were successfully propagated through 8 serial tissue-culture passages without difficulty, except that 2 attempts had to be made at the second passage of P K These experiments are summarised in the figure Significant interference was observed at almost every passage It will be recalled that in the previous paper evidence was presented that fluids from the third, fourth, and eighth passages of F E B caused colds in volunteers

Considerable effort was expended in attempts to detect known viruses It was thought that viruses occurring as contaminants would turn up as readily in the control series as in the series initiated from nasal washings, yet there seems in each passage experiment a regular difference in response between each pair of the two series of cultures

No hæmagglutinin was detected though culture fluids were tested with human, chicken, ox, mouse, and guineapig cells at



Schematic representation of serial passages of material from colds. Uninoculated cultures were passed serially in parallel with each of these Both were challenged and the difference in mean titres between the two groups—the interference index—is recorded for each passage The fifth control passage of F E B was contaminated Interference titres after this are given relative to H G P control cultures inoculated and challenged at the same time The numbers in the square representing a passage in volunteers give the proportion of volunteers developing colds

4°, room temperature, and 37°C, and the cell sheets were tested by hæmadsorption The fluids were inoculated subcutaneously, intraperitoneally, and intravenously into rabbits without obvious ill effect Similarly, guineapigs, weanling mice, and 1-day-old suckling mice were inoculated by various routes and all remained well It was not found possible to cultivate pleuropneumonia-like organisms or other aerobic or anaerobic bacteria from the tissue-culture fluids No interference was detected in cultures of calf kidney, human thyroid, or rhesus kidney cells inoculated with material which produced interference in cultures of human embryo kidney

Properties of the Interfering Agent

The preceding experiments seemed to indicate that a self-propagating factor had caused the interference and that it had probably originated in the washings We therefore attempted to find out whether its properties resembled those of the virus which caused colds in volunteers Experiments on this subject are summarised in table IV Attempts were made to demonstrate neutralisation by pooled human γ-globulin Apart from one possibly positive result these failed for technical reasons, arising from the toxicity for culture cells of the globulin used It could nevertheless be concluded that the interfering factor was ether-stable, filtrable, and destroyed by heat (56°C for 30 minutes), and exposure to pH 2 In these respects at least it was apparently identical with the virus producing colds The effect of acidity and the fact that it was self-propagating distinguished it from interferon (Lindenmann, Burke, and Isaacs 1957)

TABLE IV—SOME PROPERTIES OF THE AGENT WHICH CAUSED INTERFERENCE IN THE SERIES OF EXPERIMENTS INITIATED WITH H G P MATERIAL

Source material	Treatment	Interference index of	
		Treated material	Untreated material
Nasal washing	20% ether overnight	5 5	5 5
Second pass T C.	" " "	5 25	4 1
Sixth pass T C.	Heat at 56°C for 30 min.	1 3	2 2
Fourth pass T C.	" " " " " "	−1 2	2·6
Fourth pass T C.	Passage through gradocol membrane APD 290 mμ	2 7	2 6
Second pass T C.	Dialysis against citrate buffer pH 2 1 for 3 hr	−0 8	6 6

These results are discussed at the end of the third paper (Tyrrell and Parsons 1960)

Summary

Virus interference has been detected in cultures inoculated with common-cold material and not in cultures inoculated with control material This interference was found in cultures up to eight in series, maintained in medium 199 modified by increase in the content of glucose and addition of bovine-plasma albumin

In experiments with H G P material it was found that interference did not develop when the inoculum had been heated at 56°C, or held at pH 2 It did develop when the inoculum had been treated with ether or filtered through a gradocol membrane of average pore-size 290 mμ

SOME VIRUS ISOLATIONS FROM COMMON COLDS

III CYTOPATHIC EFFECTS IN TISSUE CULTURES

D A J Tyrrell
M D Sheff , M R C P

R Parsons
B Sc Bristol

From the Common Cold Research Unit (Medical Research Council), Salisbury, Wilts

When trying to make the sixth tissue-culture passage of strain P K , described in the previous paper (Hitchcock and Tyrrell 1960) we found that a new batch of medium 199 was toxic to the cultures Several different batches of this medium were therefore obtained These were found to be non-toxic and so an attempt was made to make another passage In cultures maintained with one of the new batches of medium 199 a definite cytopathic effect was observed after inoculation with tissue-culture fluids thought to contain P K and H G P viruses A preliminary study of this unexpected observation has now been made

All the materials and methods were as described in the previous papers with the modifications to be found below

Results

It was thought that the cytopathic effect might have occurred because the new medium 199 contained less bicarbonate (0 09%) than those used previously (0 16%) This was confirmed when it was found that other media with a low bicarbonate concentration allowed the appearance of a cytopathic effect The development of this effect has been observed in kidney cell cultures, mainly of rhesus monkey but also of human and cynomolgus monkey tissue maintained in a variety of media and inoculated with from one to many thousand infectious doses of virus We give here a general description of these degenerative changes, which seem to be basically the same under all the conditions studied

2–7 days after inoculation foci of degeneration are seen They consist of a few cells in which the cytoplasm becomes refractile or looks like ground-glass The cells draw away from the surrounding cells and the cytoplasm becomes irregular in outline with long branching processes and small nodules on the cell surface Later the cells become rounded and fall off the glass In some cases the foci remain almost unchanged for over a week. In others they gradually extend In human kidney cultures the foci appear throughout the sheet and extend

TABLE I—CYTOPATHIC EFFECT OF H G P VIRUS IN VARIOUS TYPES OF CULTURES OF KIDNEY CELLS

Species	Variations in the conditions of culture*	Average score of degeneration†	
		At 5 days	At 10 days
Rhesus	Standard	1 2	2 5
	Primary cultures	1	1
	Primary cultures 0 1% bicarbonate	0	0
Rhesus	Standard	2 5	3
	Stationary	1 1	1 5
Rhesus	Standard	2	3
	36°C	0 5	0
Rhesus	Medium 199, 0 16% bicarbonate 36 Primary cultures	0	0
Cynomolgus	Standard	0 8	1 2
Human	Primary cultures	0 8	N D

*The standard conditions were the use of secondary cultures maintained at 33 C in a roller drum with a medium containing 2% calf serum and 0 25% lactalbumin hydrolysate in Hanks saline containing 0 03% sodium bicarbonate Deviations from these standard conditions are shown but all other conditions remained standard throughout the experiment.

†An arbitrary scoring system was used in which 0 5 represents the appearance of the first few foci of degeneration and 3 represents degeneration of all cells Groups of 3 to 5 cultures were used

centrifugally In rhesus kidney cultures, the foci appear at the extreme edge of the cultures and extend first all round the edge of the cell sheet and then gradually spread in towards the middle When progressive degeneration of the sheet occurs it only becomes complete 5–10 days after the first focus has been observed The changes thus resemble those of a very slowly progressive cytopathic effect produced by a poliovirus Typical cytopathic changes as seen in unfixed and in fixed material are shown in figs 1–3

Table I summarises the results of some typical experiments in which the effect of H G P material from the fifth pass in human embryo kidney cultures was studied in various types of cultures maintained in various media The inoculum was equivalent to 100 tissue-culture infectious doses under standard conditions of culture The extent of the cytopathic effect was increased by using secondary rather than primary monkey kidney cultures, and by waiting up to 10 days, by using 0 03% bicarbonate rather than 0 1%, 33°C rather than 36°C, and in rolled rather than stationary cultures Varying the lactalbumin hydrolysate concentration between 0 25% and 1% and the serum concentration between 0 and 4% did not prevent the cytopathic effect but there was at times some inhibition at the higher concentrations If no bicarbonate was added, cultures became very granular and there was no cytopathic effect due to virus

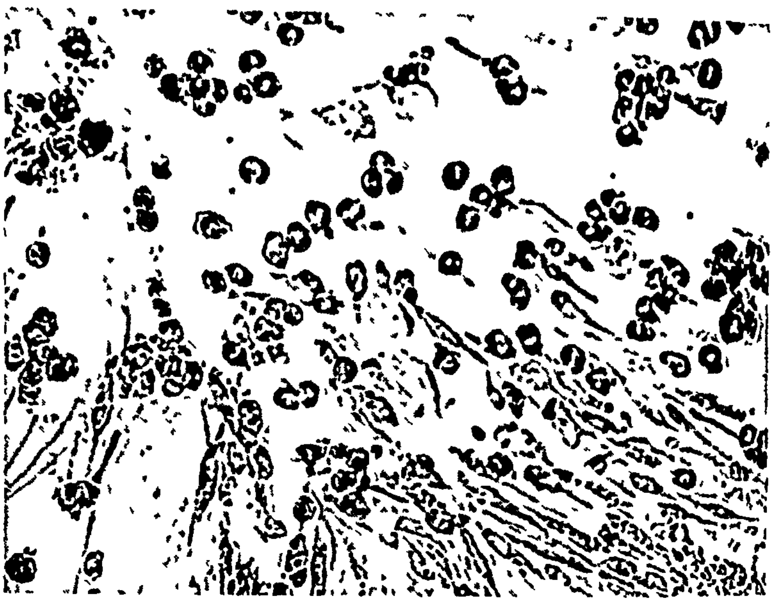

Fig 2—Similar to fig 1 but unstained (× 175).

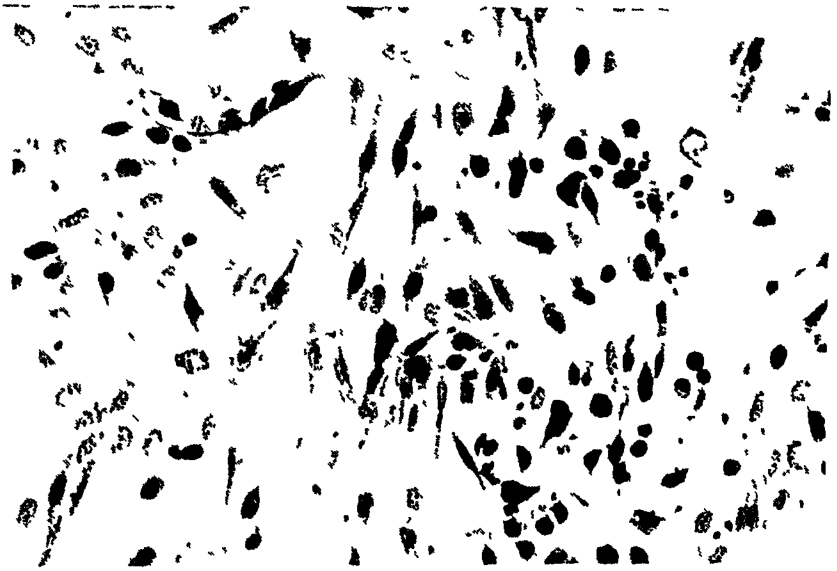

Fig 1—Secondary cultures of rhesus-monkey kidney cells maintained at 33°C in 2% calf serum, 0 25% lactalbumin hydrolysate with 0 03% bicarbonate and inoculated 8 days previously with 200 TCD_{50} of H G P virus passed 5 times in human embryo kidney cultures Some spindle shaped cells can be seen but many are rounded up and degenerate (Hæmatoxylin and eosin × 175)

We have formed the opinion that the exact way in which secondary monkey kidney cultures are set up and treated affects the development of cytopathic effect We now inoculate tubes with 0 5 ml of growth medium (Tyrrell et al 1960) containing about 30,000 cells obtained from bottle cultures The cultures are changed and inoculated about 2 days later when they each contain about 20,000 cells The cells are in patches rather than continuous sheets at this stage and the pH of the medium is about 7 The cell-count rises to about 30,000 per tube and the pH falls to about 6 5 in the controls by the end of an experiment Where there is a marked cytopathic effect the pH may be 7 or higher In other experiments it was found that there was a slight and transitory cytopathic effect in cultures of human

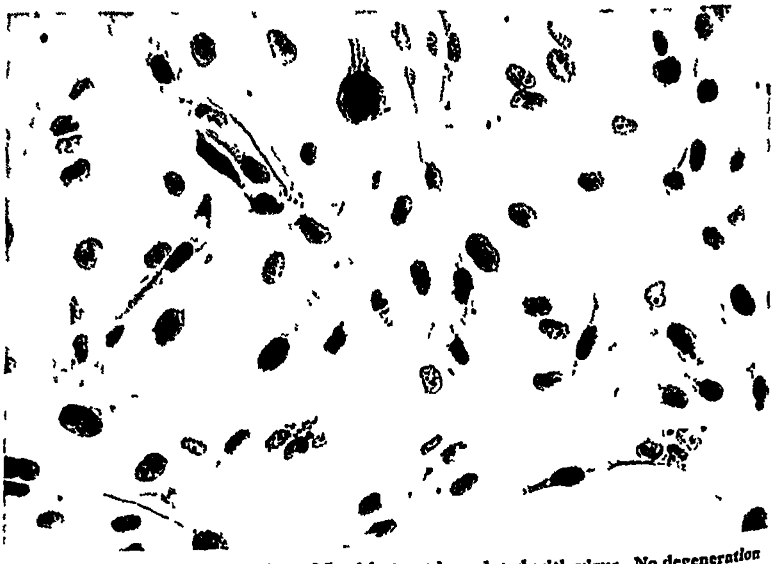

Fig 3—A parallel culture to that of fig 1 but not inoculated with virus No degeneration (H & E × 175)

TABLE II—THE RELATION BETWEEN THE CYTOPATHIC EFFECT PRODUCED BY H G P VIRUS AND THE INTERFERENCE EFFECT IN HUMAN EMBRYO KIDNEY CELLS

Type of culture *	State of cultures		
	Before challenge	After challenge †	
		Appearance	$\log_2$ Mean HA titre of challenge virus
Human kidney – H G.P	Partly degenerate	Partly or completely degenerate	1·9
„ „ – control inoculum	No degeneration	Complete degeneration	6·4
Rhesus kidney – H G.P	Partly degenerate	Complete degeneration	4·0
„ „ – control inoculum	No degeneration	Complete degeneration	2·1

* All maintained in medium containing 2% calf serum, 0·25% lactalbumin hydrolysate, and 0·03% sodium bicarbonate

† On fifth day after inoculation with H G P the cultures were challenged with Echo 11

embryo lung maintained at 33°C in 2% calf serum, 0·25% lactalbumin hydrolysate with 0·03% bicarbonate in the saline There was no effect in cultures of human thyroid or calf kidney cells maintained under these conditions

The cytopathic effect has been seen in over 300 cultures of human and rhesus monkey kidney cells inoculated with first to eighth passage material from strains H G P and P K With the F E B strain, however, cytopathic effect was seen in human embryo kidney cultures but not after inoculation into monkey kidney cultures Cytopathic effect was seen in 18 of 19 human or rhesus kidney cultures inoculated with the washings containing H G P and P K which were used to initiate the serial cultures mentioned earlier No effect was seen when the washings were inoculated into cynomolgus kidney cultures The agent causing this effect has been readily passed in series The effect has never been seen in over 100 cultures receiving control material, either fluids from cultures of the uninoculated passage series or washings from several volunteers without colds

This cytopathic effect was compared with the interference effect observed previously As table II shows, human embryo kidney cultures which showed a cytopathic effect were resistant to reinfection with Echo 11 virus while corresponding rhesus kidney cultures were not This was in line with previous findings

Dr M S Pereira of the Virus Reference Laboratory, Colindale, and Dr D Hobson of the Virus Research Laboratory, Lodgemoor Hospital, Sheffield, kindly allow us to state that in "blindfold" experiments they have detected cytopathic effects in cultures inoculated with H G P and P K strains and none in cultures inoculated with control material

Properties of the Cytopathic Agents

The cytopathic effect was not prevented by treating the inoculum with ether but it was destroyed by heating at 56 C for 30 minutes and by treatment at pH 2 The cytopathic agent also passed a gradocol membrane of APD 100 mμ The H G P agent was not destroyed by blending culture medium for 2 minutes at room temperature with 4 volumes of fluorocarbon (Arcton 63) and centrifuging lightly These experiments were done quantitatively (table III) The infectivity titrations were carried out as with other cytopathic viruses serial dilutions of virus were inoculated into groups of cultures and the final reading was taken 10–14 days after inoculation Preliminary attempts were made to identify the H G P virus by neutralisation tests using tissue cultures of rhesus or human kidney cells 100 TCD_{50} were held at 37°C for 4 hours with serum before inoculation Cultures were observed for the appearance of specific degeneration The virus was not neutralised by antisera neutralising Echo 28 (the J H and 2060 viruses) and the Coe virus, both of which produce a similar degeneration, have similar physical properties, and are associated with minor respiratory infections (Andrewes 1959) It was not neutralised by hyperimmune typing sera against poliovirus types 1–3, Coxsackie B viruses types 1–5,* nor by pooled sera against Echo viruses types 1–3 and 5–14 †

Neutralisation tests were performed with sera which had been collected from subject H G P at the onset and after the cold during which the washing yielding the H G P strain was taken the first serum had a titre of less than 5 and the second of 20

Discussion

The finding that some viruses from common colds will grow and produce cytopathic effects in cultures has been reached by following a series of clues First, as recorded in the first paper of this series, was the evidence of sur-factor of importance in producing this phenomenon Gaskell (1956) has shown that the sáme phenomenon sometimes appears after repair of occluded iliac and femoral arteries, and our clinical experience agrees with this

---

* Supplied by Dr P J Wormald and prepared by the Central Public Health Laboratory Colindale

† Prepared by Microbiological Associates, Washington, D C

Fig 3 shows the postoperative vasodilatation in case 2 On the 2nd postoperative day the foot blood-flow in the operated side was more than double the preoperative flow in either foot, and on the other side was less than at any other time Cases 1 and 6 showed the same reduction of blood-flow in the symptomless limb during the peak of postoperative vasodilatation

ROLE OF VASOMOTOR TONE IN POSTOPERATIVE HYPERÆMIA

To define the role of the sympathetic nerves in limbs with postoperative vasodilatation we studied the effect of heating the body This completely removes sympathetic vasoconstriction in the hand, but less completely in the foot (Pickering and Hess 1933) When applied to patients with postoperative vasodilatation, body-heating produced a rise in the blood-flow till approximately the same high level was attained in both feet (fig 4, case 2) When the body was cooled, blood-flow fell on both sides, but less on the operated side Similar results were found in further 2 patients and the response to body heating of all 3 patients is shown in table VI It will be seen that the notable difference in blood-flows through the two feet was largely abolished by heating the body

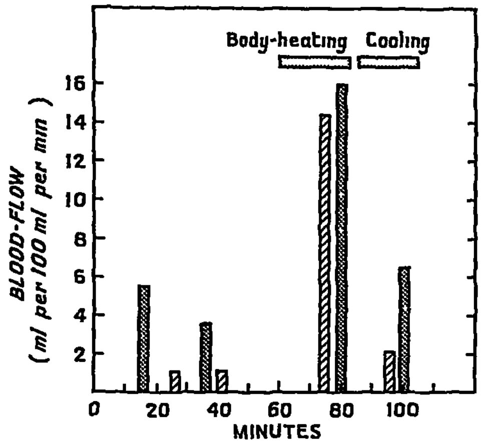

Fig 4—Case 2 effect of body heating and cooling on foot blood-flows 5 days after operation Plethysmograph temperature 32°C Stippled columns = operated limb Hatched columns = symptomless limb

These experiments demonstrate that the sympathetic nerves are still capable of altering vascular tone in the foot during the phase of postoperative vasodilatation, and that when sympathetic tone is released the vascular beds in the two feet are of similar size Hyperæmia due to a chemical vasodilator stimulus or to an enlarged vascular bed would both be expected to maintain a greater blood-flow in the affected limb even upon release of sympathetic tone Our observations on the postoperative vasodilatation are fully consistent with its being due to partial release of sympathetic constrictor tone

NATURE OF OPERATIVE STIMULUS PRODUCING VASODILATATION

Table V shows that in case 5 profound postoperative hyperæmia developed in the unaffected limb, thus the features of this case are of special interest

TABLE VI—MEAN BLOOD-FLOWS THROUGH THE AFFECTED (A) AND SYMPTOMLESS (S) FEET AFTER POPLITEAL ARTERIAL GRAFTING FLOWS IN ML PER 100 ML PER MIN BEFORE AND AFTER HEATING THE BODY

Case no	Days after operation	Plethysmograph temperature (°C)	Foot	Before heating	After heating
2	5	32	A	3 6	15 9
			S	1 1	14 5
	7	43	A	18 8	28·9
			S	13 3	28 9
3	2	30	A	3 2	3 4
			S	0 8	3 0
4	1	33	A	21 0	29 4
			S	4 2	23 8
	5	33	A	5 3	20 7
			S	3 9	17 0

This patient had a block about ³/₄ in long in the right common iliac artery, and 6 weeks before our studies a right lumbar sympathectomy had been performed elsewhere We confirmed that the right foot remained devoid of vasomotor innervation by observing that the blood-flow through this foot did not change with vigorous body heating and cooling At operation the aortic bifurcation and both common iliac arteries were mobilised by dissecting off the densely adherent periarterial tissues Controlling clamps were placed on the aorta and both common iliac arteries, and then the calcareous mass obstructing the right common iliac artery was extracted from it The incision in the artery was then closed

Fig 5 shows the foot blood-flow in this patient before and after operation, using plethysmograph temperatures of 44 and 31°C Before operation the affected side had the greater flow when the plethysmograph temperature was 31°C (owing to the previous sympathectomy), but this side had the lesser flow when the plethysmograph was 44°C (owing to the obstruction in its main artery) On the 1st postoperative day both pulses had returned in the right foot, but it was the left foot that was red and hot, being appreciably warmer than the right This difference in temperature persisted until the 7th postoperative day when once again the right foot was warmer than the left, as had been the case before operation Blood-flow measure-

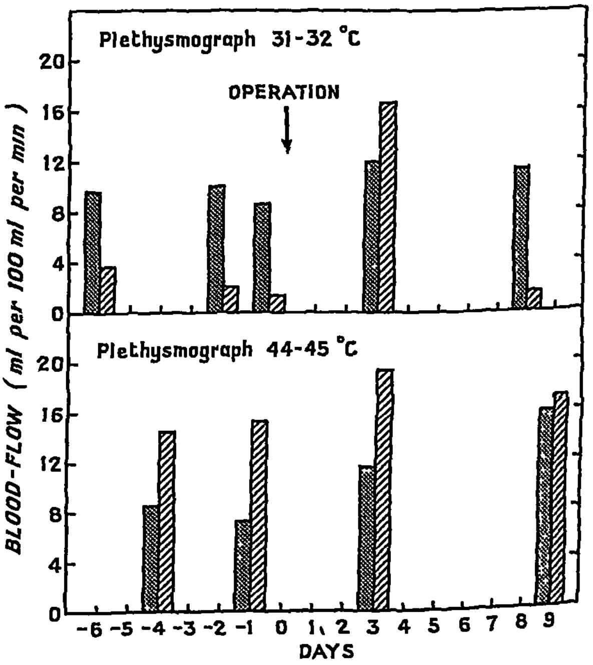

Fig 5—Case 5 foot blood-flows before and after thromboendarterectomy of the right common iliac artery The operation included dissecting and clamping the left common iliac artery There had been a previous right lumbar sympathectomy Stippled columns = right foot Hatched columns = left foot

ments (fig 5) confirmed that the left (unaffected) limb had experienced an appreciable postoperative vasodilatation which had subsided by the 8th postoperative day, whilst there was no evidence of vasodilatation of this kind on the affected side The vasodilatation must have been related to the operative interference upon the aorta and left common iliac artery, for this patient had no more than the usual rise of body temperature of 1–2 F after operation. The vasodilatation in the left foot was similar in kind, degree, and duration to that seen in other cases on the grafted side, and suggests a similar mechanism On the 8th postoperative day the blood-flow through the left foot increased in response to body-heating from 1 3 to 8 8 ml per 100 ml per min., demonstrating that the operation had not destroyed the sympathetic nerves supplying the left leg

The only factor common to the interference with this normal limb and the reconstructive operations of other patients was the handling and dissection of the main artery This suggests the possibility that postoperative vasodilatation is due to injury of the artery or destruction of the periarterial plexus of nerves The latter mechanism seems more likely in view of the other evidence suggesting that the response was mediated by a partial release of sympathetic vasomotor tone

Discussion

Striking changes followed reconstruction of the main artery in these patients One or both of the foot pulses returned during the operation or shortly afterwards, and the foot became hot and red, often for several days The blood-flow through the resting calf as well as through the foot was greater in the operated than in the contralateral limb for many days after operation

Calf Blood-flow

Intermittent claudication was largely, or completely, relieved by operation and the reactive hyperæmia returned towards the normal pattern The reversal of these abnormalities after operation suggests that in the main they resulted from a single obstruction in a main artery

The slight impairment of reactive-hyperæmia flows in the calves of both operated and symptomless limbs is probably due to further, lesser, arterial obstructions, such measurements are of value in the study of groups of patients, but the overlap with the normal deprives them of individual diagnostic significance

The response of blood-flow to ischæmia was termed reactive hyperæmia by Lewis and Grant (1925), who considered that it was occasioned by the accumulation of metabolites Further, in 1938 Grant showed that the hyperæmia following exercise was governed by the amount of exercise undertaken, and that it was independent of the sympathetic nerves Freeman (1935) claimed that a self-regulating system must be responsible for the approximate correlation which he demonstrated between the blood debt incurred during circulatory arrest and the subsequent excess flow It has been found that the excess blood-flow of reactive hyperæmia and after exercise is independent of the resting flow whether this has been elevated by heating the body (Barcroft et al 1952) or reduced by infusing adrenaline (Dornhorst and Whelan 1953) Similarly the excess flow is no greater when the effective local blood-pressure is reduced, or when arterial hypoxia is induced (Dornhorst and Whelan 1953) It was therefore postulated by Barcroft and his colleagues (1952) that two functionally independent types of vessels existed in muscle one responding to metabolites and the other under the control of the sympathetic nerves Dornhorst and Whelan (1953), however, considered that these findings were adequately explained by assuming that the removal or destruction of metabolites depended on a concentration gradient from tissues to the vessels, and not on the level of blood-flow or oxygen tension Patterson and Whelan (1955) found, like us, a poor correlation between blood debt and repayment, and a percentage repayment ranging from 50 to 200 Duff et al (1955) observed the effect of antihistamine drugs on reactive hyperæmia and found evidence for the accumulation of histamine only when the circulation had been arrested for 10 minutes or longer There is evidence that the transmural pressure of arteries may partly govern their calibre (Bayliss 1902), Folkow 1949, Greenfield and Patterson 1954), and that this mechanism may play a part in reactive hyperæmia (Patterson 1956)

Thus many factors may be responsible for reactive hyperæmia, and in these circumstances it is perhaps not surprising that there should be only an approximate relation between blood-flow debt and repayment In our subjects the repayment reflected the integrity of the arterial circulation, being greatest in the normal group, intermediate in the patient's symptomless leg, and least in their affected leg Furthermore those patients with the greatest circulatory impairment had the smallest repayments

We infer from these results that, in the healthy subject, the excess blood-flow during reactive hyperæmia is not regulated exactly to balance the debt incurred by ischæmia By the action of multiple factors this hyperæmia may be normally well in excess of homœostatic requirements and its extent largely a reflection of the integrity of the arteries

Foot Blood-flow

The major point of interest resulting from the studies on foot blood-flow is its temporary, and often large, increase following repair of the main artery, a similar temporary increase in foot blood-flow following arterial grafting was reported by Eastcott (1953) and by Gaskell (1956), who concluded that restoration of the arterial pathway—and not any other aspect of the operation—was the cause of the hyperæmia There is much evidence from our own and other studies that the arterial vessels of an ischæmic limb may be dilated, and it might be supposed that the increased flow after operation is simply due to a higher pressure within persistently dilated vessels However, as both our and Gaskell's studies show, in the ischæmic limb the vessels are more dilated in muscle than in skin, whereas the postoperative increase of flow is much more prominent in skin than in muscle In addition we have produced a similar hyperæmia in a normal limb where the only interference was dissection of the periarterial tissues Although we cannot yet identify with certainty the cause of the postoperative vasodilatation, our data suggest the tentative hypothesis that the phenomenon is due to a partial release of sympathetic vasomotor tone, caused by the destruction of the periarterial nervous plexus at operation

The effect of destroying the periarterial sympathetic nerves on the blood-flow in the limb has long been disputed, and physiological aspects have been lost sight of amid the conflicting therapeutic claims

Perivascular denervation was first suggested by Jaboulay (1899) and was later strongly advocated as a treatment for ischæmic disease by Leriche (1921) Leriche found that denuding the artery of its sheath over a length of 8 to 10 cm. caused contraction of the artery, with loss of its pulse, and a fall of the skin temperature of the operated limb lasting 3–15 hours The pulse then reappeared and the limb became noticeably warmer, its temperature exceeding that of the unoperated side by 2–3°C This vasodilatation was transitory, however, waning 5-6 days later, and vanishing within 3–4 weeks Brown and Rowntree (1925) measured the heat elimination from the hand in a patient with Raynaud's disease before and after periarterial sympathectomy After operation, the elimination increased to a maximum in 5–8 days and returned to its pre-operative level in 2 weeks In a patient with Buerger's disease, these workers found no changes in heat elimination from the hand after periarterial sympathectomy Rogers and Hemingway (1930) studied the problem in cats The change of the hindlimb volume to histamine and acetylcholine injections was measured before and after destruction of the periarterial nerves Soon after operation, vasodilatation could be shown by this method, though evidence of it had disappeared by the end of the experiment They obtained more direct evidence of vasodilatation by observing the vessels of the rabbit's ear, after destruction of the periarterial nerves of the carotid artery, the ear remained redder and warmer than the other side for 48 hours Woollard and Phillips (1932) measured the skin temperature of their own hands before and after injecting procaine around the radial and ulnar arteries With this method they were unable to detect any changes, but there was no reliable evidence of paralysis of the periarterial nerves Other published work on periarterial sympathectomy deals solely with the clinical appraisal of its sequelæ However, the time relationships of the clinical improvement in the circulation and its subsequent relapse followed, in many cases, the pattern described by Leriche

The postoperative hyperæmia exhibited by our patients is therefore similar in degree and duration to the changes recorded by previous workers after division of the periarterial nerves We therefore consider that division of periarterial nerves is the likeliest main cause of the postoperative vasodilatation here described

Summary

In 12 patients with a localised obstruction of the iliac, femoral, or popliteal artery, the arterial circulation was investigated by plethysmography before and after reconstructive operations The obstruction was relieved by an arterial homograft in 9, by an autogenous vein graft in 1, and by thromboendarterectomy in 2

After operation intermittent claudication was greatly relieved or abolished

Blood-flow through the calf was measured at rest, and during reactive hyperæmia, in 8 patients and in a control group of 12 healthy men In the affected limb, resting calf flow was sometimes equal to, or even greater than, that in the contralateral limb, but the calf reactive-hyperæmia curve had an abnormal form, and was lower than in the other limb The normal calf reactive hyperæmia was greater than that in the patients' symptomless limbs In the early postoperative period, the affected limb had the larger resting flow, and its reactive-hyperæmia curve became higher and assumed a normal shape

The percentage "repayment" by reactive hyperæmia of a calf blood-flow "debt" incurred by 5 minutes' circulatory arrest averaged 134 in the normal group, 103 in the patients' symptomless limb, and 74 in the affected limb These findings suggest that reactive hyperæmia is not a nicely balanced response, but a vasodilatation induced by many independent causes with the integrity of the arteries as a limiting factor

Foot blood-flow was measured serially in 7 patients Preoperatively it was usually, but not invariably, reduced on the affected side After operation the foot flow in the operated limb increased in all patients, in 5 of them exceeding the flow in the other foot for several days Evidence is adduced that this postoperative vasodilatation is due to partial release of sympathetic tone induced by interruption of the periarterial plexus of nerves

These studies were suggested by Sir George Pickering, to whom we are grateful for encouragement Our thanks are also due to Prof C G Rob for allowing us to study his patients

It has been known for many years that plant cells are more susceptible to damage when irradiated under aerobic than under anaerobic conditions, and in experiments with the roots of *Vicia faba* Thoday and Read (1947) showed that, as the oxygen tension rises from zero, the radiosensitivity also increases—steeply at first but more slowly later In 1953 Gray et al established that in mice the sensitivity of the Ehrlich ascites tumour is raised by high oxygen tension Clinically, Churchill-Davidson et al (1955, 1957) demonstrated the enhanced effect of radiation on patients breathing oxygen at 3 atmospheres pressure, and reported some promising results with the method

This treatment under oxygen at high pressure involved the use of a metal pressure chamber, general anæsthesia to enable patients to tolerate the chamber, and bilateral myringotomy to prevent damage to the middle ears As ill patients could not have repeated anæsthesia, two large treatments only were given, and, because of the time taken to anæsthetise and prepare the patients, only a few could be treated The normal method of irradiation by fractionation daily for a number of weeks could not be applied, and the treatment could not be used as a routine for large numbers of patients A further disadvantage was that the anæsthesia might well decrease the sensitivity of the tumour cells, thus partially counteracting the beneficial effects of the high-pressure oxygen (Burdick 1953)

In an attempt to obviate these disadvantages, we decided to investigate the possibility of treating large numbers of conscious patients under high oxygen tension with the usual fractionation techniques For this purpose we

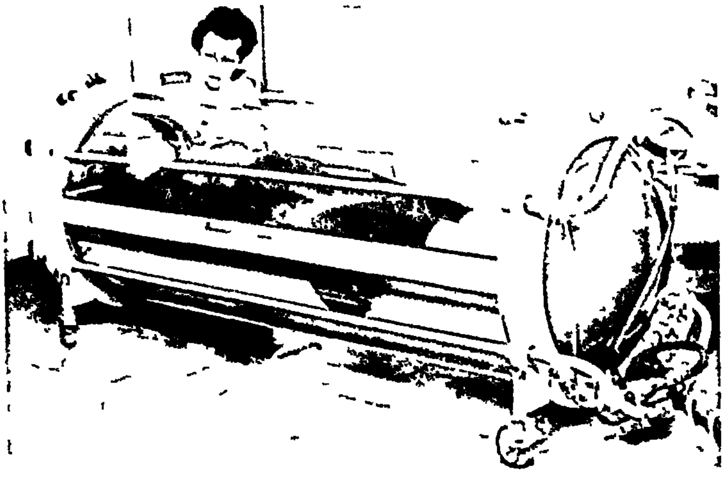

Fig. 1—Complete chamber

needed a pressure chamber which would be acceptable to the average conscious patient, and would be applicable to routine radiotherapy techniques, without shortening the time in which the machines were in use. The special problems posed by these requirements were:

1. Production of a mobile chamber, able to withstand at least 1 atmosphere above ambient, which would allow continuous visual and auditory contact with the patient.
2. Elimination of any features which would make the conscious patient unwilling to undergo this form of treatment.
3. Elimination of the risk of an explosive decompression, which might endanger bystanders and affect the patient because of the sudden drop in pressure.
4. Development of a system of pressurisation which would at least minimise ear and sinus pain or damage (otitic sinus barotrauma). These syndromes are caused by difference of pressure between the environment and the sinus and middle-ear cavities.
5. Provision of adequate ventilation, to give full oxygenation and to prevent retention of water vapour and carbon dioxide inside the chamber.

The Chamber

A transparent chamber, pressurised through an electromechanical automatic control system, was designed and constructed (fig. 1). It is a 'Perspex' cylinder (6 feet long and 26 inches in internal diameter) mounted on wheels. Its ends are fibre-glass domes supported in aluminium rings. One end dome is removable and is used for entrance of the patient, who lies on a movable bed (fig. 2). In an emergency the chamber can be depressurised from 1 atmosphere above ambient within half a minute. To remove the risk of an explosive decompression the perspex cylinder is made as a double skin whose interlayer is partially filled with glycerin. This distributes the stresses between the two parts of the structure, and, in the remote possibility of the inner skin failing, the pressure would be retained by the outer skin.

All the control gear is mounted on a small panel remote from the chamber and connected to it by a flexible hose 100 feet long. The flow of oxygen from cylinders to the chamber can be varied; in practice a flow of approximately 5 cubic feet per minute has been found satisfactory. This gives good pressurisation, rapidly sweeps residual air out of the chamber (which has a volume of about 20 c. ft.), provides a comfortable environment for the patient, and prevents the build-up of water vapour and carbon dioxide. The pressure inside the chamber is controlled by a motorised spring-loaded valve on the outlet side. This valve, when set, gives a constant rate of pressure change; this setting can be varied from 1 to 2 lb. per sq. in. per minute by adjusting the speed of rotation of the motor. The layout of the control system is shown in fig. 3. An intercommunication system is incorporated in the apparatus so that the patient, the operator of the chamber, and the radiographer giving the treatment, can be in constant communication with each other.

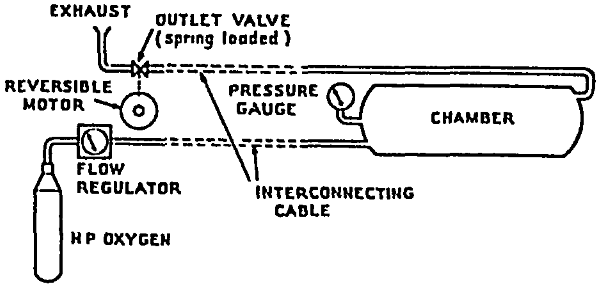

Fig. 3—Layout of the chamber pressurisation system

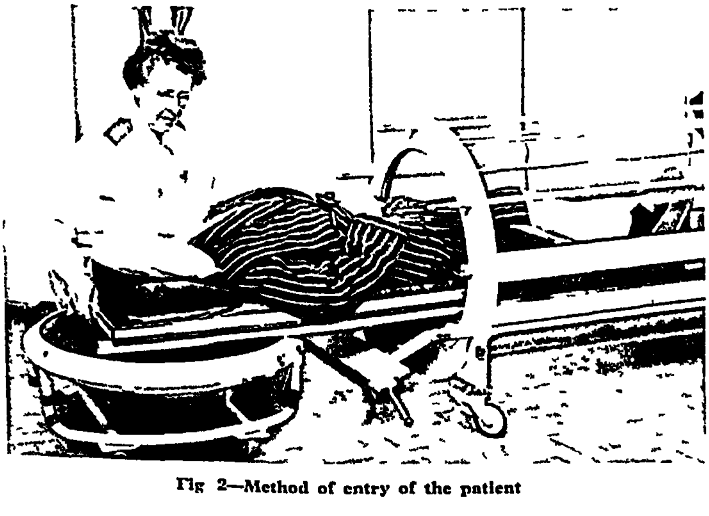

Fig. 2—Method of entry of the patient

Experience of the Method

This chamber has been employed since January, 1959, for the treatment of patients with carcinoma of the bronchus by the techniques in use in the radiotherapy department at University College Hospital (Hilton and Pilcher 1955). These entail daily treatment for from four to seven weeks. The patients have withstood their radiotherapy well and the transparency and ease of communication have enabled them to enter the chamber with confidence. As in normal techniques, the irradiation is applied under visual control and the patient can be observed throughout. The mobility and small size of the chamber make possible its use with the standard radiotherapy units. The total time from entering the chamber to the end of depressurisation is usually under half an hour, and, as pressurisation and depressurisation take place outside the treatment room, the radiotherapy machine can be in continuous use The whole technique is simple and has not necessitated any increase in staff. It should be noted that although the rate of pressure change used is normally 2 lb per sq in per minute, there has been no pain or damage in ear or sinus This may possibly be attributed to the smooth pressurisation attained by the automatic control system

In view of the success of this chamber, we hope to develop the technique so that it can be used for treating conscious patients at pressures up to 4 atmospheres absolute

We are grateful to Dr Gwen Hilton, director of the radiotherapy department, University College Hospital, and to Dr C F Barcford, managing director, Vickers Research Ltd , for their invaluable help and encouragement in this project

MANY patients with hyperparathyroidism present with renal calculi and not with the classical features of bone disease, hyperphosphatasia, hypercalcæmia, hypophosphatæmia, and hypercalciuria, in some of them disturbances of serum-calcium or plasma-phosphorus are absent

Because of the known effect of parathyroid hormone on the renal tubules (see, for example, Hiatt and Thompson 1957) many investigators have studied the renal handling of phosphate in hyperparathyroidism Phosphate-clearance (Kyle, Schaaf, and Canary 1958), and the ratio of phosphate-clearance to creatinine-clearance (C_1/C_{Cr}) (McGeown 1957), have been investigated extensively, a phosphate-excretion index (P E I) (Nordin and Fraser 1956) and percentage tubular reabsorption of phosphate (%T R P) (Goldman, Gordan, and Chambers 1957, Thomas, Connor, and Morgan 1958) have been derived from the clearance ratio But none of these indices of phosphate disturbance have given an unequivocal distinction between patients with hyperparathyroidism and those with renal calculi associated with other conditions

We have used a technique described by Anderson (1955a) to study the theoretical renal phosphorus threshold in proven cases of hyperparathyroidism, and in other patients with no evidence of parathyroid overactivity So far a clear distinction has emerged between patients with hyperparathyroidism and those with idiopathic renal calculi

Patients Studied

GROUP 1 *Hyperparathyroidism* (Cases 1–7)

Seven patients had hyperparathyroidism proven by surgical removal and histological examination of adenomata Six presented with renal calculi and one had malignant hypertension without renal calculi or nephrocalcinosis None had biochemical or radiological evidence of bone disease

GROUP 2 *Renal calculi* (Cases 8–17)

Ten patients with calcareous renal calculi were comparable in age and range of renal function with those of group 1 These patients were not considered to have hyperparathyroidism, and therefore none was explored for parathyroid lesions

GROUP 3 *Idiopathic hypercalciuria* (Cases 18–20)

Three patients had idiopathic hypercalciuria Case 18 had had multiple renal calculi for 9 years Case 19 had nephrocalcinosis Case 20 had had recurrent renal calculi for 20 years, and exploration of the neck in October, 1957, revealed normal parathyroid glands

GROUP 4 *Others* (Cases 21–28)

Two patients had idiopathic phosphaturia, in one it was associated with renal glycosuria, and in the other with amino-aciduria Three were normal hospital patients Two were cases of acromegaly One was a case of steatorrhœa with osteomalacia

Methods

Measurement of Renal Phosphorus Threshold

Outline of procedure—A linear rise in plasma-phosphorus of about 8 mg per 100 ml was produced by an intravenous infusion of buffered sodium phosphate over a period of 180 minutes Urine was collected at 30-minute intervals, and blood was taken at the mid-point of each urine-collection period The inorganic phosphorus in each blood and urine sample was estimated (In this paper " plasma-phosphorus " refers to the plasma-inorganic-phosphorus level) Plasma-phosphorus was then plotted against time to confirm that a linear rise had occurred, and the plasma-phosphorus at the mid-point of each urine-collection period was obtained by interpolation The theoretical renal phosphorus threshold was calculated from a second graph with the urinary phosphorus excretion (mg per min) in each period as ordinate and the corresponding plasma-phosphorus as abscissa The regression line was calculated The plasma-phos-

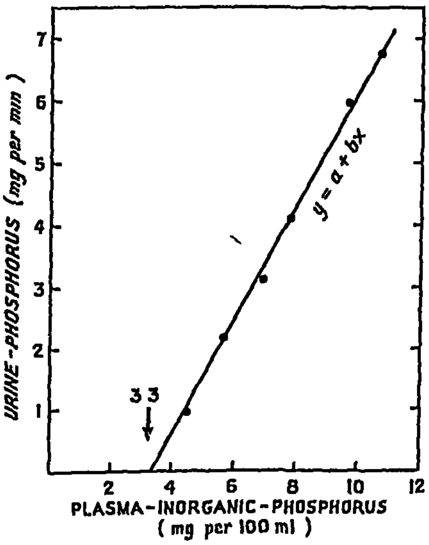

Fig 1—An example of the determination of the theoretical renal phosphorus threshold (case 15)

The six points represent the plasma-phosphorus levels and urinary output of phosphorus during six periods of infusion The regression line was calculated ($y = -3 2 + 0 96x$), and the point at which it cuts the abscissa, defined as the theoretical renal phosphorus threshold, was 3 3 mg per 100 ml

* Less than 150 mg calcium per day for 5 days

phorus corresponding to the point at which the regression line cuts the abscissa is defined as the theoretical renal phosphorus threshold. Results of a typical infusion are shown in fig 1.

Details of the infusion—The buffered sodium phosphate (pH 7·4) comprised Na_2HPO_4 52·4 g and $NaH_2PO_4.2H_2O$ 11·5 g in 1 litre of sterile distilled water, this contains 1·37 g of inorganic phosphorus per 100 ml. The infusions were begun at about 10 A.M., with the patient fasted for 12 hours, and resting in bed. A linear rise in plasma-phosphorus was produced by injecting every 60 seconds a calculated volume of phosphate from a sterile graduated 20-ml syringe through polyethylene tubing into an arm vein. Initially we used the method of Anderson (1955a) for calculating the desired rate of infusion. We have since found it possible to inject an initial volume of 0·7 ml per min., increasing progressively to 1·6 ml per min. at 180 minutes in most patients. If there were gross abnormalities in the size of the patient or the glomerular-filtration rate (G.F.R.), the rate of injection was adjusted by calculation. About 200 ml of the phosphorus solution (90 mM of P, 163 mEq of Na) was infused. A water diuresis was maintained by the patients' drinking 250 ml of water every 30 minutes. Urine specimens were obtained at approximately $^1/_2$-hour intervals, timed to the nearest $^1/_2$ minute. Women had an indwelling many-holed catheter inserted, and the bladder was washed out with sterile isotonic saline after each collection period. At the intended midpoint of each urine-collection period 8 ml of blood was taken from an indwelling needle in a limb not being used for infusion, mixed with 120 units of phosphate-free heparin, and centrifuged immediately.

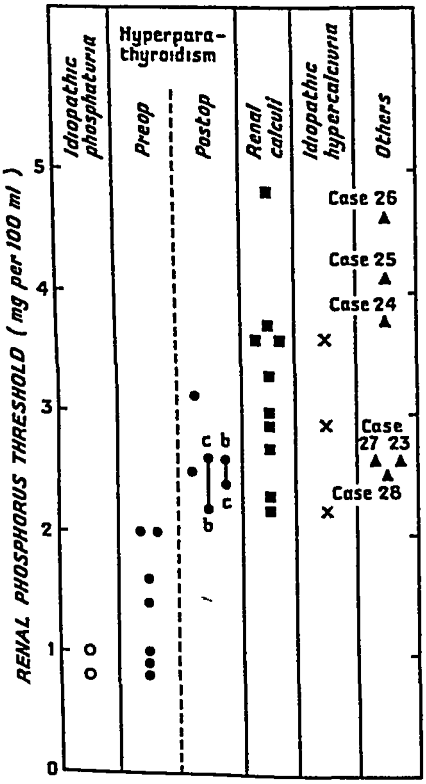

Fig 2—The theoretical renal phosphorus threshold in the twenty-eight patients investigated.

In the group of determinations after parathyroidectomy, the points coupled by a line represent two determinations in the same patient at (*b*) 11 days and (*c*) 5 months after operation. (See table VI.)

Other Investigations

Just before most of the infusions, blood was taken from the fasting patient for estimation of the serum-calcium, plasma-ionised-calcium, plasma-phosphorus, and plasma-creatinine. The creatinine output during each period of infusion, the pre-infusion fasting C_P/C_{Cr} ratio from 8 A.M. to 10 A.M., and the creatinine-clearance were determined, the P.E.I. was also calculated.

In twenty-one infusions the phosphate reabsorbed by the renal tubule was calculated in successive 30-minute periods, the difference between phosphate excreted in the urine (mg per min.) and in the filtered load (G.F.R. × plasma-P) was regarded as the reabsorbed phosphate. During the periods chosen the plasma-phosphorus level was higher than the renal-phosphorus threshold, and the tubular reabsorption of phosphorus was presumably maximal (Tm_P). In five patients the G.F.R. was measured by inulin infusion, in the remainder endogenous creatinine-clearance was used.

Analytical Methods

Calcium Kramer and Tisdall (1921), and the Eppendorf flame photometer. Ionised calcium Rose (1957). Phosphorus Briggs (1922). Creatinine Peters (1942). Urea Peters and Van Slyke (1932). Inulin Roe, Epstein, and Goldstein (1949).

Normal Limits

The following normal ranges have been established for this laboratory:

	Mean ± S.D.	*95% limits*	*80% limits*
Serum-calcium (mg per 100 ml)			
Kramer and Tisdall	9·9±0·66	8·6–11·2	9·0–10·8
Flame photometer	9·3±0·53	8·2–10·4	8·6–10·0
Plasma phosphorus (mg per 100 ml)	3·6±0·64	2·3–5·0	2·7–4·4

Plasma-ionised-calcium (mg per 100 ml) normal range 5·1–6·9 (16 determinations in eight subjects)

Values outside the 95% limits are regarded as definitely abnormal, while those between the 80% and 95% limits are suspicious, values within the 80% limits are regarded as normal. Serum-calcium levels determined by flame-photometry are marked with a dagger (†) in the tables. Normal values for the C_P/C_{Cr} ratio vary with the plasma-phosphorus level, and we have judged our results by the criteria of McGeown (1957). The normal range of P.E.I. is ±0·12 (Nordin and Fraser 1956), patients with hyperparathyroidism would be expected to give values higher than −0·12. Tm_P in fasting normal subjects on a normal diet is reported by Anderson (1955a) as 4·4–5·5 mg per min., and by Thompson and Hiatt (1957) as 73–199μM (2·3–6·2 mg) per min.

Results

The results are summarised in fig 2.

GROUP 1 *Hyperparathyroidism* (Cases 1–7, tables I and IV)

a Before Parathyroidectomy

The renal phosphorus threshold was 2·0 mg per 100 ml or less in all seven patients.

In four patients (cases 1, 3, 4, and 6) the serum-calcium was normal at least once during the preoperative period,

* Less than 150 mg calcium per day for 5 days † By flame photometry

and on four separate occasions in case 1 when on a normal diet Case 6 had a consistently normal serum-calcium, but it rose to 11 1–11 3 mg per 100 ml after a low-phosphorus diet (610 mg per day) supplemented with aluminium hydroxide for 10 days

Whenever they were both measured, the plasma-ionised-calcium was normal when the serum-total-calcium was normal In particular, in case 6, the plasma-ionised-calcium did not exceed 6 4 mg per 100 ml (which is within our normal range, and that of 5 9–6 5 mg per 100 ml described by Lloyd and Rose 1958)

On the day of infusion, the fasting plasma-phosphorus at 10 A M was not definitely abnormal in six patients Repeated determinations (not necessarily fasting) gave at least one abnormal reading in three patients (cases 1–3), one patient (case 4) had a consistently normal plasma-phosphorus level, and three patients (cases 5–7) had levels that were never definitely abnormal

In the six patients studied, the urinary calcium excretion exceeded 250 mg per day on a normal diet In three of them the daily urinary calcium excretion fell to less than 150 mg when the calcium intake was reduced to less than 150 mg per day for 5 days, we regard this as a normal response (see Hodgkinson and Pyrah 1958) In the other three cases the urinary calcium excretion remained abnormal

In all cases the creatinine-clearance was within the range 72–89 ml per min The response to 5 units of pitressin tannate in oil intramuscularly was normal in one with a maximum urine specific gravity of 1024 (case 3), impaired in three (cases 4, 6, and 7), and not tested in the other three

The C_P/C_{Cr} ratio and the P E I were normal in case 1 on three occasions, and in case 4 on the only occasion it was measured Total plasma-proteins, alkaline phosphatase, and potassium were normal in all patients

b After Parathyroidectomy (table IV, fig 2)

The renal phosphorus threshold, redetermined in four patients (cases 2–4 and 6) 10–13 days after parathyroidectomy, was found to be more than 2 0 mg per 100 ml in each case There was no significant change in their creatinine-clearance, but the response to pitressin improved in the three patients in whom it was impaired before parathyroidectomy

The renal phosphorus threshold, reinvestigated in two patients (cases 2 and 3) 5 months after parathyroidectomy, was more than 2 0 mg per 100 ml

GROUP 2 *Renal Calculi* (Cases 8–17, tables II and IV)

The lowest renal phosphorus threshold found was 2 2 mg per 100 ml

The serum-calcium was definitely normal in nine patients and suspicious (10–10 4 mg per 100 ml by flame photometry) in one (case 13) Plasma-ionised-calcium was normal in the nine cases in which it was measured, including case 13 The fasting plasma-phosphorus was normal in seven patients, and suspicious (2 3–2 6 mg per 100 ml) on one occasion in cases 11–13

Urinary calcium excretion was normal in the three patients investigated The range of renal function assessed by creatinine-clearance or blood-urea was similar to that of the patients with hyperparathyroidism The ratio C_P/C_{Cr} and P E I were normal in five cases (8–11, and 13), abnormally high in case 12, and not measured in cases 14–17

GROUP 3 *Idiopathic Hypercalciuria* (Cases 18–20, tables III and IV)

The renal phosphorus threshold was 2 2 mg per

* Less than 150 mg calcium per day for 5 days † By flame photometry

100 ml. or higher in three patients with "idiopathic hypercalciuria".

In one patient (case 19) hypercalciuria persisted when the dietary intake of calcium was less than 150 mg. for 5 days; in the other two the urinary calcium output fell to less than 150 mg. per day.

Case 20 had on one occasion a serum-calcium level of 11·2 mg. per 100 ml., but it was normal on five other occasions. Case 18 had suspicious serum-calcium levels (10·9 mg. per 100 ml.) on three occasions. Plasma-ionised-calcium, plasma-phosphorus, C_P/C_{Cr} and P.E.I. were never abnormal.

GROUP 4

a Idiopathic Phosphaturia (Cases 21–22, tables III and IV)

The renal phosphorus threshold in two cases with a "renal phosphate leak" were among the lowest found in this series (0·8 and 1·0 mg. per 100 ml.). Both had consistently low levels of plasma-phosphorus, high C_P/C_{Cr} ratios, and high P.E.I. The serum-calcium was normal.

b Miscellaneous (Cases 23–28, tables III and IV)

Six other patients who had no evidence of hyperparathyroidism all had renal phosphorus thresholds above 2·4 mg. per 100 ml. Although case 28 had severe osteomalacia, bone biopsy showed "Wide osteoid seams are present. There is no increased osteoblastic or osteoclastic activity" (Dr. J. L. Pinniger). This helps to exclude secondary hyperparathyroidism.

One patient with inactive acromegaly and mild pituitary insufficiency (case 27) had an abnormally high C_P/C_{Cr} and P.E.I.

Measurement of Tm_P

In fourteen infusions the reabsorbed phosphate varied greatly in successive periods and the Tm_P could not be defined. These fluctuations were not related to changes in G.F.R., and they occurred when both inulin and creatinine were used as measures of G.F.R. There was no significant change in plasma-creatinine during any infusion. Data from a representative group of patients are shown in table V.

27	80–93	2·0 1·3 1·4 0·4 0·6	2·5

a = preoperative
b = 10–13 days after parathyroidectomy
c = 5 months after parathyroidectomy
‡ Inulin-clearance.

The extremes of variability are shown in cases 2(*a*) and 27. In most cases showing a consistent trend, tubular reabsorption increased in successive periods, but in four (cases 2[*c*], 10, 13, and 27) it decreased.

In cases 2 and 3 phosphate reabsorption had increased 10–13 days after parathyroidectomy, but in case 4 no significant change was detected, although the renal phosphorus threshold had increased considerably. Moreover, in cases 2 and 3, the Tm_P 5 months after parathyroidectomy was indistinguishable from the preoperative value, while the renal phosphorus threshold had increased to within normal limits, and there was no evidence of active hyperparathyroidism.

Results of Phosphate Infusion

The plasma-phosphorus level 15 minutes from the end of the infusion was 9–15 mg. per 100 ml. The mean rise in plasma-phosphorus achieved in hyperparathyroid patients was 7 mg. per 100 ml., and in patients with renal calculi 8·7 mg. per 100 ml.

A fall in serum-calcium was noted in all infusions in which it was investigated, and it varied from 0·6 to 4·1 mg. per 100 ml., the greatest falls being in patients who had high fasting serum-calcium levels. In one patient with severe osteomalacia (case 28) the fall in serum-calcium from 7·9 mg. to 5·2 mg. per 100 ml. was accompanied by tetany which responded to intravenous calcium gluconate.

None of the patients experienced malaise, rigors, or venous thromboses.

Discussion

Theoretical Renal Phosphorus Threshold

Operation confirmed the diagnosis in all seven patients who had renal phosphorus thresholds of 2·0 mg. per 100 ml. or lower, and who were considered to have hyperparathyroidism.

The renal phosphorus threshold was of particular value in three patients in whom at least two of the classical diagnostic criteria were normal. Case 1 had normal serum-calcium levels on four of eleven occasions, had a normal urinary calcium output when on a low-calcium intake, had a normal C_P/C_{Cr} ratio and P.E.I. on three occasions, and a normal response to two calcium infusions

(Nordin and Fraser 1954) Case 4 had a consistently normal plasma-phosphorus, and a normal C_P/C_{Cr} and P E I Initially case 6 had consistently normal levels of serum-calcium and plasma-ionised-calcium, but lowering the phosphorus intake did eventually elevate the serum-calcium above normal This patient also had a normal urinary calcium excretion when on a low-calcium intake

The fact that the renal phosphorus threshold rose to the normal range within 13 days of parathyroidectomy in the four patients tested indicates that it depends on parathyroid function It seems to be a valuable index for the identification of hyperparathyroidism in patients with renal calculi or nephrocalcinosis

We must point out that, with the exception of case 20, none of the patients with idiopathic hypercalciuria or idiopathic renal calculi were operated upon, and that there is slender evidence of hyperparathyroidism in some (suspicious levels of serum-calcium in cases 13, 18, and 20, and of plasma-phosphorus in cases 11, 12, and 13) but this diagnosis was considered very unlikely on all the available evidence

The renal phosphorus threshold is, of course, lowered in certain patients with primary disorders of renal tubular function (e g , cases 21 and 22), but these patients can usually be separated by the demonstration of defects such as aminoaciduria, glycosuria, or acidosis, and they lack other evidence of hyperparathyroidism

In the three normal patients (cases 23–25) the renal phosphorus threshold varied between 2 6 and 4 1 mg per 100 ml compared with Anderson's (1955a) range of 4 0–4 7 mg per 100 ml in six young adult males

Serum-calcium Levels

All seven patients with hyperparathyroidism had hypercalcæmia at some stage, although in case 6 this was only seen after a low-phosphate intake In three cases (1, 3, and 4) which were followed for 2–7 years, the hypercalcæmia was intermittent (compare Bogdonoff et al 1956, McGeown and Morrison 1959) Lloyd and Rose (1958) found increased ionised calcium and normal total calcium in two of seventeen patients with hyperparathyroidism, measurement of ionised calcium is, therefore, potentially a more sensitive index than measurement of total calcium, but in our experience it has not yet proved to be so (see also Loken and Gordan 1959)

Plasma-phosphorus Levels

The plasma-phosphorus levels overlap considerably between all four groups of patients, and, like many investigators (including Goldman et al (1957) and McGeown and Morrison (1959), we think this is an unreliable index of hyperparathyroidism

Impaired renal function may result in normal or raised plasma-phosphorus levels in patients with hyperparathyroidism From the data of Goldman and Bassett (1954), this seems unlikely when the G F R is higher than 50 ml per min All our patients with hyperparathyroidism had creatinine-clearances greater than 70 ml per min , and we consider that the frequent presence of normal plasma-phosphorus levels was not due to renal dysfunction but is a feature of the disease

Phosphate-clearance

Clearance of phosphate by the kidney shows much diurnal variation, is minimal at 8 A M , and is related to the plasma-phosphorus level (Stanbury 1958) The C_P/C_{Cr} ratio and the % T R P $\left(=\left[1-\frac{C_P}{C_{Cr}}\right]\times 100\right)$ have been used to correlate the phosphate-clearance with G F R Nordin and Fraser (1956) have related the clearance ratio to plasma-phosphorus as a P E I It is generally agreed that these indices of phosphate-clearance measured at endogenous levels of plasma-phosphorus do not unequivocally distinguish patients with hyperparathyroidism Thus we have found that the C_P/C_{Cr} ratio and P E I were normal in two patients with hyperparathyroidism and abnormally high in one patient (case 12) with renal calculi, and one with inactive acromegaly (case 27)

McGeown (1957) reported similar findings of normal C_P/C_{Cr} ratios in three out of thirteen proven cases of hyperparathyroidism, all of which had normal renal function These three patients and one other had a normal P E I Normal values of phosphate-clearance in hyperparathyroidism have been described by Kyle et al (1958) and normal % T R P S have been reported by Goldman et al (1957) and Thomas et al (1958)

The converse finding of abnormal indices of phosphate-clearance in the absence of any other evidence of hyperparathyroidism has been described by Nordin and Fraser (1956) and McGeown (1957) in patients with renal calculi, and by Thomas et al (1958) in patients with hypercalcæmia associated with myeloma or carcinoma

Maximum Tubular Reabsorption of Phosphate

When the plasma-phosphorus level is progressively raised, the quantity of phosphorus reabsorbed by the renal tubule will theoretically reach a maximum (the Tm_P)

Anderson (1955b) and Thompson and Hiatt (1957) have suggested that the Tm_P is lowered in hyperparathyroidism There is doubt, however, about the constancy of Tm_P measurements

Anderson (1955a) demonstrated a Tm_P in six normal young adults studied carefully under basal conditions On the other hand, Longson et al (1956) found that in some subjects the phosphate reabsorption varied considerably during an infusion (perhaps because of alterations in G F R), and also varied from day to day in any individual Thompson and Hiatt (1957) describe similar findings, including changes possibly due to diet In our own experience the Tm_P has shown considerable changes during fourteen out of twenty-one infusions, particularly in hyperparathyroid patients This inconstancy has been noted with both inulin-clearance and creatinine-clearance as the measure of G F R

It has been noted above that the results in two patients before and five months after parathyroidectomy were indistinguishable Moreover there was no distinction between patients of group 1 (e g , case 4) and other patients (e g , cases 13 and 27) Reynolds et al (1959) report similar findings in eight proven cases of hyperparathyroidism Tm_P is clearly influenced by many factors, of which parathyroid function is only one, and it is therefore not the parameter of choice in assessing hyperparathyroidism

Conclusion

In this investigation the theoretical renal phosphate threshold has been the most useful single parameter for assessing hyperparathyroidism From the patients' point of view it is much quicker than studying the effect of low-calcium or low-phosphate intake, and it makes possible the investigation of inpatients within 24 hours

Summary

The renal phosphorus threshold has been shown to be abnormally low in hyperparathyroidism, and it is of particular value in recognising hyperparathyroidism in patients who only have renal calculi It may be abnormal when other parameters are normal

Other indices of phosphate excretion, based on plasma-phosphorus levels, phosphate-clearance, or maximal tubular reabsorption of phosphate, are less valuable

Our grateful acknowledgments are due to Mr J M Pullan, who performed all the parathyroidectomies on the patients under our care, to Dr H K Goadby for permission to study case 5, to Mr R H O B Robinson and Mr T W Mimpriss for permission to study some of the cases with renal calculi, and to Dr J Hawkins, Mr R Hurst, and the staff of the William Dunn laboratory for their technical assistance

CHOLESTEROL-BINDING CAPACITY OF SERUM GLOBULINS IN NORMAL AND ATHEROSCLEROTIC SUBJECTS

SEFIK KAYAHAN
M D Istanbul

From the Department of Pharmacology and Therapeutics, University of Istanbul, Turkey

WATER-INSOLUBLE hydrophobic cholesterol exists in a state of colloidal solution in biological systems The colloidal cholesterol-containing aggregates are complex structures with respect to size, configuration, and composition Their essential constituents are not only the plasma-lipids but also proteins—namely, α and β globulins (Chargaff 1944, Weinhouse 1943, Hueper 1945) Some qualitative alterations in the protein moieties of the cholesterol-containing micelles may occur, and this may influence atherogenesis (Katz and Stamler 1953) Indeed, electrophoresis (Barr et al 1951) and ultracentrifugation (Gofman 1950, Gofman et al 1950) have revealed such alterations in the lipid-containing micelles of the plasma

On the other hand, electrophoretic and biochemical investigations on atherosclerotic intimas showed that the lipid-containing globulins of atheromatous plaques are not normal, and that the lipid-binding capacity of these globulins is increased (Kayahan 1959) This shows that proteins are important in the pathogenesis of atherosclerosis

In atherosclerotic patients the absolute level of the blood-cholesterol is sometimes normal, but in people with high blood-cholesterol the incidence of atherosclerosis is high (Gubner and Ungerleider 1949, Gertler and Garn 1950) The purpose of this investigation was to determine the lipid-binding capacity of the serum globulins in normal subjects, in atherosclerotic patients with normal blood-cholesterol, and in patients with hypercholesterolæmia and arteriosclerosis

TABLE I—LIPID BOUND BY 1 G OF α-β GLOBULIN IN SERUM (MG LIPID PER G GLOBULIN)

Origin of serum		Cholesterol	Lipid
Atherosclerosis	Serum-cholesterol level		
Absent	Normal	98 (69–154)	472 (323–668)
Present	,,	102 (72–167)	496 (342–688)
,,	Raised	181 (165–263)	962 (743–1169)

Figures are means of 10 measurements with the ranges in parentheses

Materials and Methods

The cholesterol, total lipid, and α and β globulins were estimated, and the cholesterol and total lipid contents of 1 g of α-β globulin were calculated. The serum lipids were then extracted with ether Electrophoresis showed that this had not denatured the serum proteins significantly After the ether extraction, the total lipid and cholesterol remaining in the serum were estimated again. The lipid-containing ether was evaporated to dryness, and the lipid fractions were redissolved in the serum which was washed with ether These mixtures were incubated at 37°C for 20 hours They were then centrifuged at 3000 r p m for 30 minutes, and the undissolved lipids were discharged Electrophoresis revealed that the added lipids were bound again to α and β globulins

The total lipid and cholesterol contents of the serum specimens were estimated again, and with these and previous values, the quantities of cholesterol and total lipid combined with 1 g of α-β globulin were calculated

Results

Table I shows the quantity of cholesterol and total lipid bound to 1 g of α-β globulin in the serum of normal subjects and atherosclerotic patients The values for normal subjects were 98 and 472 mg, and the corresponding values for patients with atherosclerosis and high serum-cholesterol level were 181 and 962 mg

Table II shows the amount of cholesterol and total lipid combined with 1 g of α-β globulin of the serum in four groups of experiments

Conclusions

The tables show that there is considerable difference in the lipid-binding capacity of the serum globulins of normal subjects and of patients with hypercholesterolæmia and atherosclerosis The serum globulins of the latter combine with twice the amount of lipids extracted from the serum of either atherosclerotic patients or normal subjects The lipid-binding capacity of the serum globulins of normal subjects, on the other hand, is much less

The serum globulins of patients with atherosclerosis and normal serum-cholesterol levels behave like those of normal subjects

These results suggest that there are structural alterations of the serum globulins in patients with hyper-

Figures are means of 10 experiments with the ranges in parentheses cholesterolæmia Electrophoresis and ultracentrifugation of the serum lipoproteins also support this view On the other hand the lipid-binding capacity of the globulins of aortic intima has also been found to be increased in atherosclerosis (Kayahan 1959)

These findings support the view that the lipid-binding capacity of the globulins of the serum and intima may determine the plasma-lipid level and the lipid accumulation in atheromatous plaques of the intima, and that the metabolic changes of the lipid-binding globulins of the serum and intima may be of primary importance in the pathogenesis of atherosclerosis

I am grateful to Prof Sedat Tavat, head of the department of pharmacology and therapeutics, for his interest and encouragement in this work

A SINGLE-DOSE TREATMENT OF THREADWORMS IN CHILDREN

RICHARD H R WHITE
M A, M B Cantab, M R C P, D C H
MEDICAL REGISTRAR AND PATHOLOGIST, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON, W C 1, LATELY MEDICAL REGISTRAR, EVELINA CHILDREN'S HOSPITAL

JON W SCOPES

MEDICAL REGISTRAR, EVELINA CHILDREN'S HOSPITAL, LONDON, S E 1

A HIGH proportion of town-dwelling children are infected with threadworms ("pinworms") and the majority apparently have unimpaired health (White 1956) However, the *Enterobius vermicularis* occupies the cæcum and appendix, and its relation to appendicitis has long been debated

That two common complaints may coexist is not surprising, but a causal relationship has not yet been firmly established, although Duran-Jorda (1957) provided good supportive evidence In a careful histological study of 691 excised appendices, he found that the 52 which contained threadworms were all inflamed, and he also demonstrated that the enterobius invades the substance of the appendix, causing a breach of the mucosa which would theoretically permit the entry of intestinal bacteria These findings accord with the views of Faust (1955), while Wilkinson (1959) believes that threadworm appendicitis is a clinical reality

Most cases of enterobiasis are treated for æsthetic reasons or because of perianal irritation, but, from the above evidence, it is arguable that treatment is also justified as a preventive measure

In treating enterobiasis with piperazine, White and Standen (1953a) achieved a cure-rate of 97%, using 50–75 mg per kg body-weight in divided daily dosage for seven days In the case of ascariasis, it has been established that single doses of piperazine citrate, phosphate, and adipate, equivalent to 4 g of piperazine hexahydrate, yield a cure-rate of over 80% (Goodwin and Standen 1958)

The action of piperazine has been studied by Standen (1955), who showed that pig roundworms, immersed in a modified Baldwin's solution containing a 1/560 concentration of piperazine citrate, were immobilised in six to twenty-four hours, yet continued to metabolise and recovered when removed and placed in a piperazine-free medium Goodwin and Standen (1954) also observed that specimens passed after piperazine treatment in man recovered when incubated at 37°C in piperazine-free Ringer's solution Since threadworms and roundworms are both nematodes it seems reasonable to suppose that the action of piperazine on both is similar

Bumbalo et al (1958) treated 37 infected children with a single dose of piperazine-citrate syrup (70 mg per lb body-weight, up to a maximum of 3 g) but could achieve a cure-rate of only 43% They later obtained cure-rates of 86% by giving a dose of 3 g, regardless of age, and repeating it after four days, and of 91% using a dose of 3 g on three consecutive days

Theoretically, the aim of treatment should be to maintain an adequate concentration of piperazine within the intestine long enough to ensure complete evacuation of all the paralysed worms by normal peristalsis However, there is considerable individual variation in intestinal motility, and Bockus (1944) has shown that in some people complete elimination of waste food-products from the bowel may take as much as four days In these "slow excretors" a single-dose treatment might fail, since parasites which have not been expelled may recover from the paralytic action of piperazine This possibility was recognised by Standen (1955) who, when treating ascariasis with a single dose of piperazine citrate, recommended the use of a purge in costive patients We thought that, in combination with a single dose of piperazine, standardised senna ('Senokot') would be more suitable than a saline purge, because its mode of action—namely, stimulation of muscular contraction of the colon through Auerbach's plexus—is physiological and reliable (Burgess 1958) Moreover, it is non-irritant (Douthwaite and Goulding 1957, Fairbairn 1958) and non-toxic (Hawkins 1958)

A palatable compound containing piperazine phosphate and standardised senna, in the form of flavoured granules ('Pripsen') was prepared and offered to us for evaluation We could hardly hope to exceed the cure-rate of 97% previously attained, but we thought that, with this preparation, the length of treatment of enterobiasis might be reducible without prejudice to the results

Investigation

Material and Methods

40 grains (2 6 g, approximately one-teaspoonful) of pripsen granules contain piperazine phosphate 1 g and standardised senna equivalent to 7 mg of sennosides A and B, in a flavoured base The control preparation contained an equivalent amount of piperazine phosphate, but no senna, it was almost identical in appearance and taste For the trial the two preparations were issued by the manufacturers in weighed doses, as compounds D and E, and their identity was not disclosed until the results had been analysed With each preparation, children of 2–5 years inclusive received 120 grains (= 3 g of piperazine phosphate) while those of 6–12 years received 160 grains (= 4 g) It was felt that in practice this scheme would be simpler than one based on body-weight

182 cases of enterobiasis were detected among medical and surgical admissions to the Evelina Children's Hospital, by identification of ova on adhesive '*Cellophane*' swabs taken from the perianal region in the morning, before bathing and toilet (Graham 1941) Infected

children were treated alternately with compounds D and E, which were given at bedtime, accompanied by a drink or mixed with milk, water, or jam. Perianal swabs were then taken on ten successive days, beginning on the morning after treatment.

We considered that (1) the rate of disappearance of ova after treatment would indicate the rapidity with which worms were expelled, and (2) during the first ten days after treatment the results would not be prejudiced by autoinfection, since maturation from ovum to oviposition is believed to take four to six weeks.

Every slide was examined by an experienced technician and the appearance of one or more ova constituted a positive swab. The criterion of cure was seven negative swabs (Mac Keith and Watson 1948), which meant that any child showing a positive swab after the third day was counted a failure.

Results

In 60 cases the child was discharged from hospital before ten post-treatment swabs could be obtained, and these cases have been excluded from the trial. Of the 122 remaining for analysis, 59 had received pripsen and 63 piperazine phosphate alone. 57 (97%) of the former and 58 (92%) of the latter fulfilled the criteria for a cure (see table), and of the cured cases, those treated with pripsen showed a more rapid clearance-rate (see figure). These differences, though not statistically significant, are in the expected direction.

Side-effects

Of the children treated with pripsen, 4 vomited during or immediately after administration, 1 was afterwards found to be cured and 3 had to be excluded. The majority had one to four soft or loose motions next day but only a few complained of abdominal discomfort. We have met only one instance of frank diarrhœa, occurring in a 4-year-old boy (not included in this trial) who was accidentally given 320 grains of pripsen (= 8 g. of piperazine phosphate). He had completely recovered within twenty hours. One child who received the control preparation had transient diarrhœa and vomiting and another complained of nausea. On the whole both compounds were readily accepted by most of the children, and no systemic toxic effects were observed.

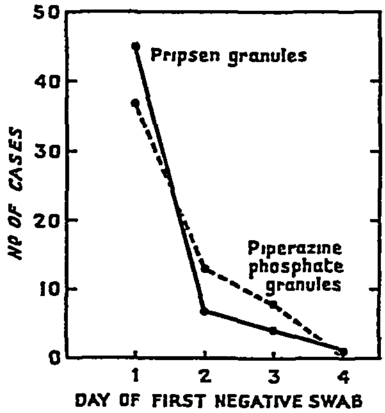
Discussion

These results show that a high cure-rate of enterobiasis can be achieved with a single dose of pripsen. Since, however, Bumbalo et al. (1958), using a single dose of piperazine-citrate elixir, had a cure-rate of only 43%, we were somewhat astonished to find that in our control group, treated with granules of piperazine phosphate alone, the corresponding rate was 92%. With a dose of 70 mg. per lb. body-weight and a maximum of 3 g., some of Bumbalo's cases almost certainly had a slightly smaller total dose than ours, but this may not be the full explanation of the wide discrepancy. Standen (1955) found no difference in the in-vitro activity of piperazine citrate and phosphate solutions, but it is conceivable that the granular preparations used in the present trial may have physical properties which retard absorption from the alimentary tract and thus favour the maintenance of a higher concentration in the large bowel. The absorption and excretion rates of this particular preparation have not yet been studied.

PERCENTAGE CURES

Treatment	Number of cases			% cures
	Total	Failures	Cures	
Pripsen	59	2	57	97
Piperazine phosphate	63	5	58	92

While the majority of the cured children showed no positive post-treatment swabs, a number gave positive swabs for one, two, or (in 1 case only) three days. During this time some of these children must become reinfected, and treatment should therefore be repeated, the best time for repetition probably being one or two weeks after the initial treatment. With single-dose treatments the toxic effects sometimes described during seven-day courses (Sims 1953, White and Standen 1953b) have not been seen by either Bumbalo et al. (1958) or ourselves. In our trial the total dose of piperazine used in each child was less than half that hitherto used in a seven-day course.



The rate of clearance as indicated by the day on which the first of seven or more negative swabs was found.

With its high cure-rate, lack of toxicity, ease of administration, and simplicity of dosage, we regard pripsen as, at present, the remedy of choice for enterobiasis. Fuller studies are needed, however, to determine the precise role of its senna component and also the pharmacological properties of the granular form in which the piperazine phosphate used in our trial was presented.

Summary

For treatment of threadworms the results obtained in 59 children given 'Pripsen' (a new granular compound containing piperazine phosphate and standardised senna) are compared with those obtained in 63 children given piperazine phosphate alone. Though both preparations were given as single doses, the cure-rates were much the same as those reported with seven-day courses of piperazine.

The doses of piperazine were less than half those hitherto used in seven days' treatment, and there were no toxic effects.

Using a single dose of piperazine-citrate elixir, Bumbalo et al. (1958) had a much lower cure-rate, and further work is needed to elucidate the possible pharmacological advantages of the granular preparation of piperazine phosphate, as well as the precise part played by the senna component.

We wish to thank the consultant staff of the Evelina Children's Hospital for allowing us to treat their patients, the nursing staff for their constant help, and Mr. F. J. Gibbs for examining the slides. The pripsen and piperazine-phosphate granules were supplied by Westminster Laboratories Ltd.

BIOCHEMICAL NORMALS IN NIGERIANS URINARY 17-OXOSTEROIDS AND 17-OXOGENIC STEROIDS

J C EDOZIEN
M D , M Sc N U I , M R C P E
HEAD OF THE DEPARTMENT OF CHEMICAL PATHOLOGY, UNIVERSITY COLLEGE, IBADAN

In the course of routine analyses of urine from Nigerian patients at University College Hospital, Ibadan, it was observed that the urinary 17-oxosteroid excretion per 24 hours was significantly lower than values quoted in the literature and lower than was found in European patients In view of the increasing importance attached to the study of adrenal cortical hormones, it seemed desirable to find out the significance of these low values Assays were accordingly made on the urine of healthy Nigerian adults in order to establish normal values with which to compare the figures obtained from abnormal urine The results of this survey are here reported.

Materials and Method

The subjects studied included forty-five male and fifty-five female Nigerians aged 20–30

Twenty of the males were laboratory staff (two doctors and eighteen student laboratory technologists) The other twenty-five males were labourers Thirty of the females were student nurses resident in the nurses' home at University College Hospital, Ibadan, while the other twenty-five were relations or wives living with the twenty males mentioned above The 24-hour urine samples were collected into Winchester bottles containing 10 ml of concentrated hydrochloric acid as preservative Creatinine excretion was measured in all the urine samples, only three showed a creatinine output of less than 1 g per 24 hours, and these were excluded from the series As a check on the methods, urine samples of six healthy male European laboratory technologists, aged 25–30, working at University College Hospital, Ibadan, were also analysed

Urinary 17-oxosteroids were determined by the method described by Moxham and Nabarro (1956) The 17-oxogenic steroids were estimated by Moxham and Nabarro's (1956) modification of the method of Appleby et al (1955), in which the pre-existing oxosteroids are destroyed with sodium borohydride, and the glucocorticoids are then oxidised with sodium bismuthate For the determination of creatinine in urine the alkaline-picrate method of Bonsnes and Taussky (1945) was used

Results

The mean 24-hour urinary output of the six Europeans was 16 5 mg for 17-oxosteroids and 15 4 mg for 17-oxogenic steroids These figures are near the values given by other workers (Barnett et al 1946, Moxham and Nabarro 1956) The urinary 17-oxosteroids and 17-oxogenic steroids in the Nigerians are presented in table I, adult males excreted about 50% more 17-oxosteroids than adult females The output of 17-oxogenic steroids was only slightly higher in males than in females (10%). The urinary output of 17-oxosteroids and 17-oxogenic steroids was about 35% lower in Nigerians than in healthy adult Europeans of comparable age This was seen in each sex

TABLE I—URINARY STEROID EXCRETION IN ADULT NIGERIANS (as mg per 24 hours)

Males	
17 oxosteroids	10 1±3 2 (4 1–20)
17-oxogenic steroids	10 6±2 7 (5 3–18 9)
Females	
17-oxosteroids	7 2±2 7 (4 0–15 0)
17-oxogenic steroids	9 7±2 0 (6 5–15 0)

To determine whether this difference has racial backgroud or whether it depends on socioeconomic factors, the Nigerian results were analysed into two income groups The results are shown in table II Group M_1 comprises the twenty male laboratory workers and M_2 the twenty-five male labourers F_1 comprises thirty student nurses, and F_2 the relatives and wives of group M_2 In both males and females, improvement in economic means produced significant increase in the mean urinary output of 17-oxosteroids and 17-oxogenic steroids The urinary excretion of 17-oxosteroids correlated more closely with income than did the urinary 17-oxogenic steroids The effect of nutrition was further demonstrated by measuring the 17-oxosteroid excretion in a male nephrotic at various levels of protein intake The dietary protein was changed weekly, and urine for steroid analysis was collected on the 6th and 7th days at each level of protein intake The results are shown in table III

TABLE II—EFFECT OF INCOME ON THE URINARY STEROID EXCRETION OF NIGERIANS

17-oxosteroids (mg per 24 hours)		17-oxogenic steroids (mg per 24 hours)	
M_1	M_2	M_1	M_2
12 7±3 8	8 3±1 7	12 1±3 7	9 4±1 6
0 001>P		0 01>P>0 001	
F_1	F_2	F_1	F_2
8 5±2 8	5 8±1 0	11 1±3 1	9 1±1 2
0 001>P		0 01>P>0 001	

Discussion

Barnicot and Wolfsson (1952) also found low urinary 17-ketosteroid-levels in Nigerians (average excretion 7 97±0 48 mg per 24 hours), and there was no difference between Nigerian students resident in London and a group of Nigerian labourers working at Oshodi Friedman (1954) and Ramachandran et al (1956) reported low values for Indian adults, and Lugg and Bowness (1954) found similar low values for Malayans in Malaya It is significant that all these people lived in areas of endemic undernutrition, especially as regards protein

The urinary neutral 17-oxosteroids reflect androgenic

TABLE III—EFFECT OF PROTEIN INTAKE ON THE 17-OXOSTEROID EXCRETION OF A MALE NEPHROTIC

functions, in the female they are produced entirely by the adrenal cortex, and in the male by the adrenal cortex and testes The testes contribute a third of the neutral urinary 17-oxosteroids The androgenic hormones have important metabolic effects, causing retention of nitrogen and phosphorus The urinary 17-oxogenic steroids measure the excretion of 17-hydroxycorticosteroids, which are important in the metabolism of protein, carbohydrate, and fat In view of the role of the adrenal hormones in metabolism, it is not surprising that the production of these hormones, and hence the excretion of their metabolites, is in some way related to the nutritional state

It has been suggested that the low steroid excretion in Africans is due to poor liver function and consequent failure to convert androgenic hormones efficiently into neutral 17-oxosteroids But a recent survey (Edozien 1958) revealed no evidence of impairment of liver function in apparently healthy Nigerians Further, Barnicot and Wolfsson (1952) found no significant difference in the mean values for the recovery of testosterone in Africans and Europeans The alternative explanation suggested by my data is that a dynamic relation exists between the level of food intake—and particularly protein—and the production of adrenal hormones

Summary

Urinary 17-oxosteroids and 17-oxogenic steroids in Nigerians have been studied The mean excretion per 24 hours of 17-oxosteroids and 17-oxogenic steroids was lower than in Europeans

Among the Nigerians the urinary steroid excretion varied according to the socioeconomic background This should be borne in mind in evaluating the results of urinary steroid analyses in Africans and other subjects from areas of endemic undernutrition

I wish to thank Mr J M. Pescod, F I M L.T , for technical assistance, Miss L Bell, principal sister-tutor, University College Hospital, Ibadan, and Dr D Mendel, of the department of physiology, University College, Ibadan, for their cooperation over the samples, Dr Mendel for the figures for nitrogen intake from the nephrotic patient

From the Third Department of Medicine, University of Budapest

Oliguria or, in more severe cases, azotæmia is known to occur in dehydration As we have shown, both hæmodynamic and tubular factors contribute to the impairment of renal function As a result of the fall in blood-pressure and of concentration of the plasma (i e , increased colloid osmotic pressure) the filtration pressure in the glomeruli decreases (Gomori 1954, Gomori and Podhradszky 1937, Gomori et al 1939, Margitay-Becht and Gomori 1938) The reduction of glomerular filtration can clearly be shown by the clearance method (Gomori 1954, McCance and Widdowson 1937, Margitay-Becht and Gomori 1938, Takacs and Kállay 1957) The slowing of the circulation in dehydration is obviously followed by reduction of the blood-supply to the kidneys and deterioration of their function (Gomori 1954, Gomori et al 1939, Takács and Kallay 1957) At the same time tubules undergo anatomical changes which lead to the " passive " rediffusion of urea (Gomori et al 1949, 1954, Kenney 1949)

The question might arise whether humoral factors also contribute to the development of oliguria in dehydration We have shown that antidiuretic-hormone activity does not increase in dehydration, and thus increased antidiuretic-hormone activity is unlikely to be a factor (Gomori, Varga, and Jakab 1958) On the other hand, we have shown (Gomori, Glaz, et al 1958) by biological methods (Tait et al 1952) in dogs that, in dehydration following obstruction of the pylorus, aldersterone-like activity greatly increases in the blood of the adrenal-gland veins This increase may explain the reduction of sodium excretion—i e , oliguria Using likewise biological methods, Luetscher and Curtis (1955) found increased aldosterone-like activity in the urine of a patient with pyloric stenosis, and Bartter et al (1956) recorded this finding in patients with reduced salt intake and induced thirst According to these workers, reduction of extracellular space leads to the increase of aldosterone-like activity

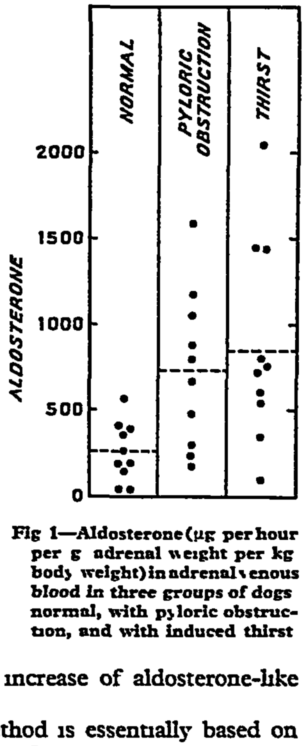

Fig 1—Aldosterone (µg per hour per g adrenal weight per kg body weight) in adrenal venous blood in three groups of dogs normal, with pyloric obstruction, and with induced thirst

Because the biological method is essentially based on the detection of a salt-retaining factor, it seemed desirable to determine both aldosterone and hydrocortisone in dehydration by quantitative chemical analysis

Accordingly we induced dehydration in dogs by obstructing the pylorus, as in our previous experiments (Gömöri and Podhradszky 1937, Gomöri et al 1939, 1954, Gömöri, Glaz et al. 1958, Gömöri, Varga, and Jakab 1958), while another group of dogs was starved of food and water for 48 hours After 48 hours aldosterone and hydrocortisone were estimated in the blood of the adrenal glands In order to determine hormone secretion, the dogs were treated with heparin and were anæsthetised with chloralose Adrenal venous blood was collected by cannulating the left adrenolumbar vein with a polyethylene catheter located peripherally at the point of venous inflow from the left adrenal gland All tributaries to the adrenolumbar vein in this region—other than the adrenal veins—were ligated, and the adrenolumbar vein was obstructed at its junction with the inferior vena cava. By this procedure the flow of venous blood from the left adrenal gland was diverted from its normal path into the catheter

---

* Present address Second Department of Medicine, University of Budapest

The heparin-containing plasma thus obtained was extracted with ethyl acetate and, after alkali purification, shaken from a petrol-ether solution into 70% alcohol Aldosterone was isolated chromatographically, starting with the dried residue of the alcoholic extract Chromatography was carried out by the method of Moolenar (1957) in two systems on Whatman no 1 paper Chromatography was followed by development with tetrazolium-blue, the developed formazon spots were eluted, and quantitative determination was carried out with a Beckmann B spectrophotometer

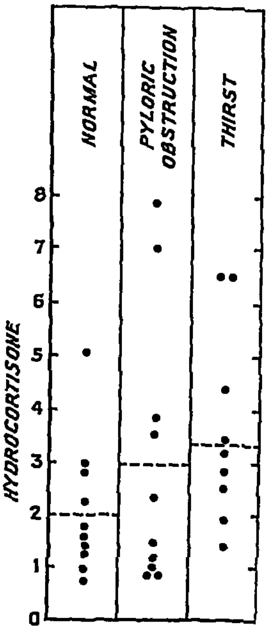

Fig 2—Hydrocortisone (µg per hour per g adrenal weight per kg body-weight) in venous blood from adrenal gland in three groups of dogs normal, with pyloric obstruction, and with induced thirst

Observations were on ten control dogs Ten dogs were kept off water, and ten further dogs had their pylorus obstructed before the experiment

Our results showed that there was a considerable increase in aldosterone secretion in most of the dogs in which the pylorus had been obstructed, as in most of the dogs simply deprived of food and water, as compared with the secretion of the control dogs (figs 1 and 2) Statistical calculations show that the change is significant ($p < 0.01$) The increase in hydrocortisone is less unequivocal, the change cannot be termed significant ($p > 0.05$, Student test)

Our experiments indicate that increased aldosterone secretion is a factor in the reduced excretion of sodium in conditions of dehydration

Summary

Aldosterone secretion in the blood of the adrenal glands of dogs increased after obstruction of the pylorus or induction of thirst The change in hydrocortisone secretion was not significant

We wish to thank Miss Maria Paul for her kind assistance in carrying out the technical work

"Medicine will become during the next ten years a more and more exact science The trend towards an increasing number of examinations using complex apparatus is bound to increase the cost of the health services Countries like the United Kingdom which enjoy a National Health Service must accept the idea that within the next ten years, real costs will be doubled, perhaps trebled "—Prof ZENON M BACQ, *New Scientist*, Jan 21, 1960, p 128

CHOLINE THEOPHYLLINATE IN CHILDREN WITH ASTHMA

A CONTROLLED TRIAL

L B STRANG *
M B Durh , M R C P
FIRST ASSISTANT

E G KNOX
M D Durh , M R C P , F S S
LECTURER

DEPARTMENT OF CHILD HEALTH, KING'S COLLEGE, UNIVERSITY OF DURHAM AT NEWCASTLE UPON TYNE

ASSESSING the effectiveness of treatment in asthma is difficult because of the many variables which may influence the condition Hence objective methods are necessary to measure the value of antispasmodic drugs

In a study of children with chronic pulmonary diseases (Strang 1960) it was shown that the ventilatory capacity in terms of the forced expiratory volume in 1 second (F E V ₁) provided a satisfactory measurement of the asthmatic child's disability It was also shown that in the severe asthma of childhood, a persistent abnormality may exist over many months, and that asthmatic attacks more often arise as exacerbations of a subacute or chronic condition than they do from a previously normal ventilatory state The studies by Kennedy and Thursby-Pelham (1956, 1958) of the ventilatory capacity of asthmatic children during treatment with cortisone and prednisone revealed a similar kind of persistent impairment

In view of these findings, it seems reasonable to base the treatment of severe asthma on long-continued daily administration of drugs which reduce bronchial obstruction and improve the ventilatory capacity Gagliani et al (1954) and Turner-Warwick (1957) have shown that choline theophyllinate produces adequate blood-levels of theophylline after oral doses, and that the levels are at least as good as those produced by other theophylline compounds

TABLE I—FAILURES TO ATTEND FOR EXAMINATION

Reason for failure	Lactose	Choline theophyllinate
Apparatus not available	2	11
Holidays	2	6
Illness	2	4
Total	6	21

An investigation of antispasmodic drugs by Gandevia et al (1957) showed that choline theophyllinate was effective in improving ventilatory capacity It causes less gastric irritation than aminophylline, and it has been suggested that it is most effective when administered over a long period (Dann et al 1954, Brown and Glancy 1955) We decided, therefore, to conduct a controlled trial of this drug, to measure its effect on the ventilatory capacity of children with severe asthma, when given four times daily for a prolonged period

The Trial

Fourteen children aged 7–13 years took part in the trial All were regarded as severe asthmatics and their parents said they were having attacks at least once every 4 weeks During the trial it became evident that most of them had a persistently impaired ventilatory capacity The trial started in September, 1958, and ended in February, 1959

TABLE II—CHEST SIGNS ON AUSCULTATION DURING TREATMENT WITH LACTOSE AND CHOLINE THEOPHYLLINATE

Chest signs	Lactose	Choline theophyllinate
Present	48	29
Absent	42	46

$\chi^2=2{\cdot}971$, P>0·05

Seven children were given 1 lactose tablet four times daily for 3 months, followed by 1 tablet of choline theophyllinate four times daily for 3 months. The other seven children started with choline theophyllinate for 3 months, and then continued with lactose tablets for 3 months. The children were allocated at random to these two groups, and the investigator who saw them did not know whether they were having lactose or the trial drug.

The dose of choline theophyllinate was 0·1 g. for children under 10 years, and 0·2 g. for children of 10 years and over. The tablets were not identical in appearance, and the parents were told that the child was to have periods on two different drugs to find out which was better. The parents were also supplied with ephedrine tablets (gr. ½) 1 of which was to be given if the child had an attack of asthma requiring treatment.

TABLE III—DYSPNŒA ON EXERTION DURING TREATMENT WITH LACTOSE AND CHOLINE THEOPHYLLINATE

Dyspnœa	Lactose	Choline theophyllinate
Present	44	30
Absent	46	45

$\chi^2=0{\cdot}972$ P>0·05

All the children were seen at 14-day intervals, but twenty-seven of the planned examinations were missed for various reasons. Each time the F.E.V.$_1$ was measured, the chest was auscultated for the presence or absence of rhonchi, and a note was made of the number of attacks of wheezing and the presence or absence of dyspnœa on exertion.

Results

Table I shows the numbers of planned examinations which were missed in each treatment group. The difference between the two groups was largely due to the spirometer not always being available.

Clinical Data

At the end of the trial five patients thought that choline theophyllinate was more effective, two thought lactose was more effective, and seven thought there was no difference. The number of attacks of asthma in the two groups was compared by calculating the differences in the mean numbers of attacks per visit for each child in the two periods. The mean difference was 0·43 attacks more in the lactose periods, and this did not differ significantly from zero (t=0·322, P>0·05). The frequency of rhonchi was not significantly different in the two groups (table II), nor was the frequency of dyspnœa (table III). No symptoms due to drug toxicity were observed.

TABLE IV—SUCCESSIVE READINGS OF F.E.V.$_1$ AS % OF NORMAL FOR HEIGHT IN EACH TREATMENT PERIOD

Case no.	First 3-month period		Second 3-month period	
	Lactose	Mean	Choline theophyllinate	Mean
1	63, 64, 51, 53, 66, 68	57·5	82, 68, 50, 50, 73, 75	66·3
3	78, 71 90 65, 63 60	71·2	69, 34, 29 74, 77	56·6
5	51, 55 81 59 50, 70, 67	61·9	85 27, 61 55 68, 72	61·3
7	78, 99, 97 50, 74, 90, 72	80·0	100 76, 85, 75, 82	83·6
9	55, 56, 62, 41, 51, 60, 74	57·0	63 81 85, 75, 82	83·6

14	38 34 54, 43 31 46	41·0	40, 36 40, 35 38, 45	39·0
		62·3		60·3

Mean F.E.V.$_1$ (% normal) first period (both treatments) =61·4
" " " " second " " " =64·3
Mean F.E.V.$_1$ (% normal) choline theophyllinate (both periods) =65·6
" " " " lactose " " =60·5

TABLE V—ANALYSIS OF VARIANCE (1)

Source of variation	Sums of squares	Degrees of freedom	Variance estimate	Variance ratio (F)	P
Between treatments	1067	1	1067	5·45	<0·025
Between periods	360	1	360	1·84	>0·05
Interaction between treatments and periods	485	1	485	2·47	>0·05
High order interaction and variations between children	63,795	24	2658	13·58	<0·01
Residual	26,810	137	196		
Total	92,517	164			

Ventilatory Data

The F.E.V.$_1$ results, converted to a percentage of the normal for height (Strang 1959), are presented in table IV. They were treated by analysis of variance in two stages.

The first form of analysis (table V) extracted from the total variation that due to the method of treatment, that due to the order of treatment, and that due to interaction between order and treatment. The variance-ratio test showed a significant benefit from treatment with choline theophyllinate. It also showed that the effect of order was not significant, the performances in both periods being similar. Finally, the order in which the drugs were given had no significant effect upon the response.

TABLE VI—ANALYSIS OF VARIANCE (2)

Source of variation	Sum of squares	Degrees of freedom	Variance estimate	Variance ratio (F)	P
Between treatments	1067	1	1067	5·45	<0·025
Between Children	59,698	13	4592	23·46	<0·001
Interaction between children and treatments	4941	13	380	1·94	>0·05
Residual	26 810	137	196		
Total	92,517	164			

Because of the absence of order effect it seemed justifiable to ignore order. The data were then reanalysed in a manner which would show any heterogeneity among the children in their reactions to the drug, and separate this from variation between individual mean performances. This analysis, presented in table VI, shows that almost all the heterogeneity among children was due to variation between their mean performances, and that their responses to treatment were not significantly heterogeneous.

Ten of the fourteen children had better mean performances with choline theophyllinate than with lactose.

Discussion

Analysis of the symptoms indicated some benefit from choline theophyllinate compared with lactose, but the differences were not statistically significant nor were the children's parents strongly in favour of one or the other The ventilatory data, however, clearly showed benefit from choline theophyllinate, this was independent of the order in which the drugs were given, and, therefore, of changes in weather and patterns of respiratory infection during this period The response to treatment was reasonably uniform despite considerable variations in severity

The measurement of ventilatory capacity at regular fortnightly intervals provided a representative sample of a fluctuating condition Failure of patients to attend for these examinations could bias the samples, but in the present investigation the failures to attend were almost entirely due to chance factors, and are unlikely to have influenced the result

The difference between the mean F E V$_1$s of children on lactose or on choline theophyllinate was significant but disappointingly small, and these children seem to need additional treatment of some kind We intend to assess other antispasmodic drugs and therapeutic procedures by a similar method Nevertheless, we may conclude that choline theophyllinate is an effective therapeutic agent although the benefit is small

Summary

As measured by the forced expiratory volume in 1 second, the ventilatory capacity of a group of fourteen children with asthma was altered favourably by the daily administration of choline theophyllinate

MEPHENESIN POISONING

D W BARRON
M B Belf, F F A R C S
CONSULTANT ANÆSTHETIST

T G MILLIKEN
M D Belf, M R C P, M R C P I
CONSULTANT PHYSICIAN

SOUTH TYRONE HOSPITAL, DUNGANNON, CO TYRONE,
NORTHERN IRELAND

WE describe here the clinical features and management of a patient who took an overdose of mephenesin

A housewife, aged 43 years, was admitted to hospital at 1 A M on Sept 5, 1957, as an " emergency", having been found unconscious at home one hour before Respiratory paralysis was diagnosed, and it was subsequently ascertained from her doctor that she had been given mephenesin (' Elixir Myanesin ') some days previously on account of a chronic anxiety state The patient had taken an overdose, but the exact quantity could not be determined. It was certainly not more than 6 fl oz and probably not less than 3 fl oz , so that the total mephenesin taken was somewhere between 5 5 and 11 g (She weighed 107 lb [48 7 kg]) She was not receiving any other medication at this time Six months previously she had taken an overdose of barbiturates, since when these drugs had not been available to her

The patient was comatose, but strong supraorbital pressure produced a slight response Respiration was abdominal and diaphragmatic, with intercostal paralysis Contraction of the accessory muscles of respiration was pronounced, the arms moving convulsively with each inspiratory effort Cyanosis was evident, and pharyngeal and tracheal secretions audible The blood-pressure was 110/80 mm Hg, pulse-rate 116 and regular, temperature 97° F The heart sounds were normal The pupils were moderately contracted and reacted to light, tendon reflexes were present in the lower limbs and not exaggerated, the plantar responses were extensor A catheter specimen of urine contained no glucose, acetone, albumin, or hæmoglobin.

Management

The patient was taken to the operating-theatre, where tracheobronchial toilet was carried out and a cuffed orotracheal tube inserted without difficulty The cuff was then inflated and the tube connected to the " closed " circuit of an anæsthetic machine Assisted respiration was carried out using 2 litres of nitrous oxide to 3 litres of oxygen, with carbon dioxide absorption and a " spill-over "

As soon as good oxygenation was obtained, a large-bore œsophageal tube was passed into the stomach and gastric lavage carried out with normal saline solution.

Assisted respiration was necessary for more than two hours At 3 20 A M the intercostal muscles began to work and breathing became less laboured Accessory muscles were no longer being employed, and the colour remained good

The patient, still unconscious, was now disconnected from the anæsthetic machine, but the cuffed endotracheal tube remained in situ, tracheobronchial toilet being required occasionally

This state of affairs persisted for a further seven hours, during which respiration was adequate and the patient gradually emerged from coma At the end of this period—i e , ten hours after the ingestion of the drug—the patient resented the presence of the endotracheal tube Following removal of the tube she was awake and would obey commands in a slow lethargic manner Over the next two hours she gradually became mentally alert and had no memory of events since the previous evening There were moist sounds throughout both lungs which cleared up in two days with penicillin and physiotherapy She was discharged from hospital on the fifth day, and has remained well ever since

Discussion

Goodman and Gilman (1955) state that the incidence of serious untoward effects caused by mephenesin is low They list the toxic effects as nystagmus, diplopia, lassitude, weakness, muscular incoordination, nausea, vomiting, syncope, sedation, and respiratory depression Intravenous administration may cause phlebothrombosis, hæmolysis, hæmaturia and even anuria Robson and Keele (1951) cite several workers who have shown that mephenesin has a short duration of action because it is rapidly oxidised They state that in the rabbit very large doses cause paralysis of all muscles except the diaphragm Gray (1954) also mentions that very large doses in animals produce narcosis Goodier and Goodhart (1949) used a total of 39 ml of 2% mephenesin during a partial gastrectomy, and found that relaxation was never satisfactory.

It would appear from this case that overdosage of mephenesin may produce more profound respiratory depression and sedation than has been supposed As it is being increasingly recommended for common conditions, such as anxiety, tension states, and insomnia, it should be borne in mind as a possible cause in the differential diagnosis of respiratory depression or paralysis

Preliminary Communication

BENCE JONES PROTEIN OF MYELOMA

THIS communication describes an observation on the atypical proteins associated with myelomatosis (Bence Jones proteins)[1]

Because of the shortcomings of the various heating and salt-precipitation tests for demonstrating the presence of these proteins, it is now common practice to separate the urine proteins by paper electrophoresis When the proteins have been separated and the paper strip is stained by the methyl-green/pyronin method of Trevan and Sharrock[2] for ribonucleic and desoxyribonucleic acid, a deep reddish-purple band is found at the site of the abnormal globulin Such a band has been demonstrated in 11 proven cases of myelomatosis In all these cases a positive staining reaction was obtained in both serum and urine For these studies the amount of serum seeded on to the filterpaper was 0 010 ml When investigating urine samples it was found necessary to vary the amount of urine in order to obtain a well-stained band, using the usual protein-staining agent (azocarmine B[3]) generally 0 025 ml of urine was sufficient, but occasionally it was necessary to increase this to 0 050 ml The urine specimens were not subjected to concentration by dialysis, but were seeded directly on to the filterpapers

The reaction has proved to be negative in about a hundred other electrophoretic preparations from cases of hyperglobulinæmia and proteinuria not associated with myelomatosis These sera were derived from cases of liver disease, collagen diseases, renal abnormalities, and various malignant tumours The specimens of urine were from cases with proteinuria ranging from simple albuminuria to the more complex protein losses associated with advanced nephrosis

I suggest that the method of Trevan and Sharrock may be specific for true myeloma protein

My practice is to make three electrophoretic preparations In two the serum and urine are treated separately, and in the third the urine is seeded on top of the serum on the paper strip This method permits easy comparison of the respective mobilities of the various proteins in serum and urine

Further investigations are being made of the staining material associated with the atypical globulins, particularly with regard to its staining behaviour in the presence of nucleases

Reviews of Books

Brucella Infection and Undulant Fever in Man

SIR WELDON DALRYMPLE-CHAMPNEYS, C B , D.M , F R C P , late deputy chief medical officer, Ministry of Health, chairman, joint F.A O /W H O expert committee on brucellosis London Oxford University Press 1960 Pp 196 25*s*

Brucellosis in England

HUGH R E WALLIS, M.D , M.R C P , consultant pædiatrician, Bath clinical area London A. S O O'Connor 1959 Pp 140 25*s*

IT was over thirty years ago that Sir Weldon was instructed by the Chief Medical Officer at the Ministry of Health to inquire into the occurrence of undulant fever in England and Wales Since that time he has read almost every word on the subject in many languages, he has talked to everyone who has a concern for this disease, and he has himself collected the available information on over 1500 indigenous cases His findings and conclusions are now published in a small and elegant monograph Here, without a wasted word, is all that anyone could reasonably want to know about a disease which may play only a small part in the Bills of Mortality but which remains of exceptional interest This is not, we hope, the last word from this source, but it is a good foundation on which to base further inquiries

Dr Wallis' book is less ambitious He records his observations on 42 patients whom he suspects have had undulant fever and draws some dogmatic conclusions The clinical descriptions are interesting Some of his patients undoubtedly suffered from undulant fever, but many physicians will be unconvinced by his diagnosis in at least half of the patients As Sir Weldon points out, the diagnostic value of a rise in the titre of agglutinins after an injection of brucellin is doubtful the same phenomenon can be demonstrated in some apparently normal subjects Therapeutic success is a dangerous diagnostic weapon, as the author admits, but some of his diagnoses seem to depend on little else

In spite of these two books there is still a great deal to be known about this disease About 1% of the adult population show agglutination titres of 1/160 or more it is easy to guess that these are the result of past infections but of this there is no proof It would seem dangerous to make the diagnosis (*a*) in the absence of other signs and symptoms, and (*b*) without either a demonstrated rise in titre or the cultivation of the organism from blood or marrow It is possible that today milk-borne infections are the exception Most urban milk is pasteurised. In one dairying district more than 70% of proven cases of undulant fever in the past ten years have been in those doing bovine midwifery (and these make up only 1–2% of the population) Of course they all drink raw milk—and so do 50% of the rest of the rural population—but on the farm undulant fever is a disease of the adults rather than of the children. It is indeed so much of an occupational disease that some form of specific immunisation might be of value

There has recently been some alarm about the occurrence of infection with *Brucella melitensis* in cattle in England It has not so far been transmitted to man and appears to produce a disease in cows indistinguishable from that caused by *Br abortus* To the bacteriologist the three species of brucella are distinct entities, but in fact aberrant and intermediate types occur not uncommonly It is possible that had his material been drawn from other places the bacteriologist's classification might have been different It has been general experience that Malta fever (due to *Br melitensis*) is a more severe infection in man than undulant fever caused by *Br abortus* It is conceivable that the distinction depends not upon the bacterial species but upon some biological differences in the parasite which have so far escaped notice Does passage through the goat enhance bacterial virulence? Does the severity of infection depend upon the dose received? And, for that matter, what is the minimum infective dose for man?

Horses are now luxuries and therefore denied the benefits of veterinary science enjoyed by cows and other useful animals Before it is too late someone should investigate the curious story that *Br abortus* is the principal cause of poll evil and fistulous withers in horses—i e , deep-seated and chronic abscess formation. Generally speaking, the pathological changes produced by natural infection with a bacterial parasite are much the same in all mammals On the effects of S19 vaccine Sir Weldon is, perhaps, less than fair Its introduction has certainly not yet reduced the number of human infections markedly, but the scheme is voluntary and even now less than half the calves born are inoculated Since a cow remains a useful source of milk for many years, the effects of calfhood vaccination are not likely to be dramatic What is certain is that *the number of abortions has fallen to less than a quarter*, and it is said that at the moment less than 5% of the herds in the country are infected

There is a lot to be learned from both these books—even if it is how little we know about a widespread disease

The Clinical Syndrome of Diabetes Mellitus

JOHN LISTER, M D , M R C P , consultant physician and physician in charge of diabetic clinics, Windsor group of hospitals *London H K Lewis 1959 Pp 234 35s*

THIS book fills a gap in the literature on diabetes mellitus, for it deals with the subject in enough detail to cover interestingly most facets of the syndrome and yet its size is limited to just over 200 smallish pages The script is enriched by a number of illustrations and photomicrographs, and there is a good brief historical introduction Unfortunately there are also quite a number of inaccuracies and several omissions sulphonamides are not mentioned for the treatment of urinary infections, and the recommendations for intravenous therapy after surgery could lead to gross overloading with saline Good bibliographies are supplied with each chapter, although they include by no means all the references cited in the text The book can be recommended as a useful summary of the clinical aspects of diabetes, but it should be possible to make several improvements for the second edition

Handbook of Circulation

Analysis and compilation PHILIP L ATTMAN Editors DOROTHY S DITTMER, RUDOLPH M GREBE National Academy of Sciences Philadelphia and London W B Saunders 1959 Pp 393 52*s* 6*d*

HERE is tabulation in an extreme form This book contains no text, only tables and a small number of diagrams with explanatory notes and lists of references The tables contain an enormous amount of information about every conceivable aspect of the circulation in man and animals (including birds and fish), and even translocation in plants Unfortunately, much of the material is unsuitable for tabular presentation, and generally the chief aim seems to have been to achieve comprehensiveness rather than the clear presentation of critically assessed information. The figures are often disappointing

The list of contributors, containing 326 names, reads like a *Who's Who* of American cardiology, and also includes a few authorities of international renown from other countries Such a large number may perhaps have been necessary to collect the huge volume of material, but the quality of the end-result suggests an overabundance of cooks Nevertheless the volume has undoubted value as a source of references and as a quick means of discovering whether anybody has yet published measurements of almost any parameter of the circulation in plants, animals, or man

Soil, Grass and Cancer

ANDRÉ VOISIN, membre de l'Académie d'Agriculture de France, chargé d'enseignement à l'École Nationale *Vétérinaire* d'Alfort (Paris) London Crosby Lockwood 1959 Pp 302 30*s*

THE author of this book believes that the trace elements, particularly copper, and the mineral balance of the soil play a fundamental part in the welfare of animals and human beings Few would dispute this, but most experienced agronomists and physiologists will feel that in this clever and well-documented book he has overplayed his hand In spite of the 428 references to original papers and books, which imply a profound knowledge of the subject, he presents a picture which will strike some people as lacking just that balance which he appears to revere so much in Nature The titles of his chapters tell their own story Thus we are reminded that we are dust, that a disorder of copper metabolism is one of the causes of cancer, that there are milks which produce idiots, and that agronomic original sin is the principal cause of the mental illness of our children This is strong medicine!

Experienced investigators, however, particularly those with wide interests, will find much to stimulate their minds in this book, and it will no doubt appeal strongly to those who believe that Nature, whoever she may be, is always right, and " man " is generally wrong! The book is not likely to find a ready sale among the medical profession, and it cannot be recommended for general reading without the proviso that, even if the author is not a " crank " (and we have the assurance of a scientist in the foreword that he is not), any disciple of his may very well turn into one

---

Rheumatic Fever (*A Handbook for Parents* London Empire Rheumatism Council, Faraday House, 8–10, Charing Cross Road, London, W C 2) —This six-page booklet is praiseworthy because of the importance it gives to prevention of recurrences of rheumatic fever and of subacute bacterial endocarditis by the wise use of penicillin In places it has a somewhat old-fashioned air, which might make parents anxious while leaving some reasonable questions unanswered It is free and obtainable (by doctors only) from the above address

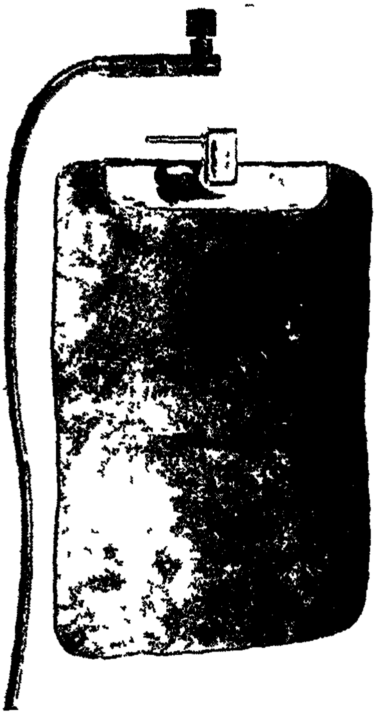
New Inventions

A SAFER DIATHERMY PLATE

THE indifferent electrode of the surgical diathermy machine receives little attention unless it causes trouble in the form of an electrical burn Occasional accidents of this kind have been traced to faults in the terminal of the electrode, or of its lead For example, the insulation between the lead and the terminal may wear and expose the underlying cable, the terminal itself may become detached from the plate and therefore transmit the whole of the current at a localised point, or the terminal may cause a deeper impression than the rest of the plate and thereby transmit a higher concentration of current



To overcome these dangers and reduce the risk of a diathermy burn, the plate illustrated (see figure) has been in use at Southmead Hospital, Bristol, for the past two years This plate has a male terminal, and the lead has a completely insulated female terminal If the lead comes adrift from the plate, there is no exposed portion to transmit the current, since the whole lead (including the clamping screw) is covered by insulating material The lead also has a double thickness of insulation from its terminal for a distance of about 18 in , the outer layer of which is transparent so that any fault at the junction of the lead and terminal can be seen easily

I am indebted to the Endoscopic Instrument Company, of 62, Shirland Road, London, W 9, for help with the design and manufacture of this plate

THE LANCET

LONDON 30 JANUARY 1960

Medical Needs of India

India has been standing on her own feet for twelve years, and in this short time her leaders have made a brave attempt to establish a Western-style democracy and bring her people into the garden of political maturity As the only Asian country to try to do this, India has great opportunities, but both people and leaders are having to face realities from which they were long protected "Independence" (the words "freedom" or "liberation" are not quite polite in India) has not removed or solved basic problems in the economic, social, or political spheres Indeed, some of these have been exacerbated by recent developments, including the accelerated increase in population

The medical profession is certainly to some extent responsible for this population pressure, but we have no need to be ashamed of that, provided that we help to cope with the consequences At present the success of efforts to raise production is just about balanced by population increase, and the average standard of living remains appallingly low—how low can only be understood by those who have lived and worked in the country It is perhaps unfortunate that so few British people have ever done this, except under the artificial conditions of war-time One of the most depressing features of the world situation is that while the developed nations are becoming richer many of the others are still becoming relatively poorer The people of the poor countries are well aware of this, but we in the rich ones are too often content to give thanks that we are not as other men

For specifically medical problems, the Government of India has inherited a health service, including teaching hospitals and schools which were British-organised but have long been staffed almost entirely by Indians, mostly trained in India Unfortunately, however, this great service was organised along semi-military lines seniority within it determines status, and status is interpreted in a military sense Even university chairs are included in the grades There is a director of medical services in each State and a director-general at the centre, and their rule is no fiction they can and do post senior people at pleasure, and determine in detail the staff of every hospital, school, or research institute There is no open competition for appointments, and the methods of administration are rigid and old-fashioned There are no local committees, medical or lay, to soften its rigours and spread a sense of responsibility One would have expected this to have been changed after Independence, but it certainly has not It is much to the credit of Indian doctors that their sense of duty to their patients is so strong, especially to the illiterate and semiarticulate who constitute the great mass General practice is outside the service, and naturally many of the more intelligent young people enter private practice as soon as they can

On the credit side there has been a big effort to train more doctors, especially by the opening of new schools No attempt has been made to introduce grades with inferior training, and the standard of qualifying examinations is being maintained with a central pool of external examiners This has meant abolishing certain of the State diplomas and closing some of the older sub-standard schools, some of which were run by Christian missionaries Though some of the missionary hospitals and schools were outstandingly good and these continue—for example, Vellore, which has plenty of candidates for its medical school—the Government does not look with favour on missionary effort On the other hand, there is political support for Ayurvedic medicine —a system which is based on the old four humours and employs cheap herbal remedies The students of Ayurveda are not, as might be imagined, humble villagers any more, but smart young men in Western trousers with tucked-in shirts who carry stethoscopes and frequent well-built modern hospitals and colleges There is much support for all this on nationalistic and religious grounds, even from distinguished "allopaths" themselves On the other hand, there is little remaining prejudice against Western medicine, even among the more backward

Postgraduate training is being expanded greatly, especially at new institutes which are attached to large specialist hospitals in the main centres and integrated with the local universities This decentralisation allows more doctors to have instruction at less expense than in the vast central institute that was at one time proposed (The whole scheme goes back to a committee formed in 1941 under the chairmanship of the late Sir BENNETT HANCE) Many specialties are still undermanned by Western standards—e g, anæsthesia and pathology The new institutes are sensibly built to suit the climate of their locality indeed, most are somewhat makeshift adaptations—frankly utilitarian and making no attempt to dazzle the foreign visitor Entry to them is open only to members of the health service, arbitrarily chosen from above

Not only has the supply of medical manpower to be considered, but also its distribution This is extremely uneven, the larger centres being overdoctored while the backward countryside, where most of the real work is to be done, relies on such expedients as midwifery by the village barber's wife There is nothing—apart from a sense of duty worthy of a saint—to attract doctors to the *mofusil* Pay is execrable, no special facilities are granted for travelling or housing, no prospect is given for refresher courses or promotion, and professional and cultural isolation may be almost complete Even in the cities pay is so poor that part-time private practice is essential, while young practitioners are attracted abroad by better prospects Moreover, a large proportion of Indian doctors still want to stay at home and live in the old way with all their relations under the same roof To have a hobby is regarded as a serious eccentricity, and this applies especially to such things as field sports, gardening, or the study of natural history—to enjoy which some Europeans will endure, or even welcome, isolation

The content of practice approaches nearer to the European now that purdah has virtually vanished (it was a Muslim importation) and the tropical diseases are within the range of eradication, though there is a great deal to be done with them yet Rational nutrition is much limited by the sacredness of the cow, and the elementary rules of hygiene are disregarded On the other hand, when malnutrition and epidemics become less overwhelming, conditions that used to be thought unusual in India grow more conspicuous—for example, rheumatic fever (even in the hot parts of the country) and especially tuberculosis The importance of family planning is becoming appreciated and Hinduism raises no religious bar to this As a corollary, child health is of growing interest to the younger parents

Textbooks are relatively scarce Indian printing and publishing are improving enormously in quality and quantity, but they have not yet caught up with the old-established British firms, and few Indian textbooks have been written Fortunately English is still the common language of educated Indians, and they use British textbooks, but far more use of such works would be made if more of them could be brought within the means both of students and of teachers Libraries are often good but cannot cater for the demand, nor can the few libraries of the British Council, which hold the only available copies of many important books, especially for postgraduates

As for practical help, it is much less easy nowadays for European doctors to settle in India even medical missionaries are being slowly eliminated as replacements fall due, fewer being allowed to enter than to leave But active help for limited periods with specific projects is needed urgently, and under such schemes as the Colombo Plan this can often be given without prejudicing a career at home The work can be deeply interesting and rewarding, and from all points of view it is a great pity that there should be difficulty in finding people to go Lecture tours by the eminent, however acceptable, are no substitute for actual work in the country At home, we can continue to welcome Indian doctors who come for postgraduate study, whether for specific courses or to work here temporarily, and must try to understand their difficulties when uprooted from their own social environment, especially coming from a land where family, social, and religious ties mean so much There is sometimes a regrettable tendency to treat senior Indians as though they were juniors they can teach much wherever they go, and more exchange professorships ought to be arranged for them On the more commercial side, we could help to provide more textbooks and well-designed equipment British manufacturers of sound drugs and equipment are not always well represented in India—in the face of competition from other countries which is not always as ethical as their own methods or products None of this, however, is a substitute for personal visits in both directions, of a length sufficient to reveal helpful attitudes and common ground Such visits can also show that our ways of control and administration are not as rigid as most Indians suppose

India is a great country striving hard to advance despite an enormous burden of poverty, ignorance, prejudice, and indifference Her doctors, in common with other professions, still look to Britain for guidance and with respect We are losing a great opportunity if we do not respond

Common-cold Viruses

AFTER 13 years of painstaking study at the Common Cold Research Unit it now seems likely that Dr ANDREWES and his colleagues have succeeded in propagating—and what is more important, recognising in vitro—viruses derived from patients with colds Prior to the work they describe in the opening pages of this issue, the only means of recognising common-cold viruses was their ability to induce colds in a proportion of human volunteers Indeed one of the major achievements of the Salisbury workers has been the devising of techniques that enable meaningful experiments to be done with human volunteers[1] Now, after many failures with orthodox conditions of tissue culture and with a variety of methods of detecting virus action, success seems to have been won

Human volunteer experiments suggested that two agents (P K and H G P) capable of causing colds were propagated in human embryo kidney cells maintained at 33°C in synthetic medium 199[2], so an intensive search for an in-vitro method of detecting virus was started HITCHCOCK and TYRRELL (p 237) showed that tissue cultures supposedly infected with Salisbury cold viruses interfered with the growth of a hæmagglutinating virus added 4 to 5 days later Thus, when tissue cultures inoculated with cold virus were subsequently infected with Echo 11 or Sendai (parainfluenza) viruses, the yield of hæmagglutinin was significantly less than in control tubes of previously infected human embryo kidney cells This enabled the simple in-vitro test to replace cumbersome human volunteer experiments for detecting virus In this way it was found that the addition of glucose and bovine albumin to the 199 medium improved the propagation of the interfering agent Using this technique, two agents were isolated from nasal washings of 4 patients examined Virus was isolated from nasal washings in the acute but not the convalescent phase Later, TYRRELL and PARSONS (p 239) found that at least 3 strains (H G P , P K , and S E B) of virus isolated from common colds could cause cytopathic changes in human embryo kidney cells, and 2 of them (H G P and P K) in monkey kidney cells as well This observation sprang from an accident trouble was experienced with toxicity in a batch of medium 199, so a new supply was secured, this happened to contain only 0 09% instead of 0 16% sodium bicarbonate, and cells in this medium showed a cytopathic effect when inoculated with H G P virus It seems that the low bicarbonate level was the all-important factor Now, sparsely grown second-generation monkey kidney cultures grown in Hanks' solution, lactalbumin hydrolysate, and 2% calf serum with 0 03% sodium bicarbonate is the preferred culture system Foci of degeneration appeared in 2 to 7 days and spread to involve the whole culture 5 to 10 days later This is a technical advance of first-rate importance As the Salisbury workers point out, their strains have not yet been conclusively shown to be common-cold viruses But careful controls to exclude the possibility of picking up a stray virus were included at every stage, also the properties (size, ether resistance, pH, and heat sensitivity) of the agents recognised by volunteer experiments, interference, and cytopathic effect are very similar The means now at hand both for tissue-culture study and human volunteer experiments should not leave this matter long in doubt It will also be possible to determine whether the Salisbury viruses are all antigenically related to each other and what relationship they bear to other recently isolated viruses

[2] Morgan, J F , Parker, R C *Proc Soc exp Biol , N Y* 1950, 73, 1

In the past decade well over 70 new viruses have been isolated from man, and many of them—notably the new members of the myxovirus (influenza), enterovirus, adenovirus, and reovirus groups—can cause severe and mild respiratory illnesses[3–5] The symptoms of infection of the respiratory tract are relatively few, and, since one virus type can cause both severe and mild disease, many authorities, particularly in the United States,[6] believe that these new viruses probably account for a significant proportion of common colds In view of their failure to isolate any of the new viruses—despite adequate technique—from their patients with colds, and also because they have failed to reproduce colds consistently in volunteers infected with these newer respiratory viruses, the Salisbury workers[4] have felt that the agent of common colds in adults as studied by them has yet to be identified Moreover, they have inclined to the view[4] that the commonest variety of common cold in adults is a distinct entity caused by a distinct virus or group of related viruses The clinical features of this sort of afebrile cold have been described by Roden[7] and consisted mainly of increased nasal discharge

Hope Simpson's careful inquiries[8] showed that many adults had as many as seven colds a year He also noted that there are many features of the epidemiology of colds which are inexplicable by the theory of simple transmission, and he brought forward evidence suggesting that relative humidity was a very important factor Thus, a low humidity favoured the development of the clinical manifestations of a cold—perhaps (though this is sheer speculation) in a way analogous to the influence of low bicarbonate levels in making manifest the cytopathic effect of the Salisbury virus on tissue culture The demonstrated capacity of the Salisbury viruses to interfere with Sendai or Echo-11 viruses may perhaps mean that the Salisbury strains will themselves turn out to be susceptible to interferon—the recently described mediator of viro-interference which has many of the properties of a viral antibiotic[9] Thus, it could conceivably be that these researches are pointing to both the cause and the cure of the common cold But as our contributors declare, great caution is required in assessing their results at this preliminary stage It has yet to be shown that these viruses cause colds, let alone all colds, and experience in virus diseases teaches that there is a very long delay between the discovery of the cause of a disease and the elaboration of adequate means for its control The Salisbury workers are to be congratulated on taking a distinct step forward, and it is to be hoped that the pace of advance will now quicken against this tiresome and economically important malady

B C G Vaccination

The second report to the Medical Research Council on B C G and vole bacillus vaccines[10] should have removed any remaining doubts[11] about the ability of these vaccines to prevent tuberculosis in young people Under the strictly controlled conditions of the trial the reduction in the incidence of tuberculosis over a five-year period that could be attributed to the vaccines was 83% for B C G and 87% for vole vaccine There seems no reason why similar reductions should not be obtained in this country when the vaccines are used under ordinary field conditions The Ministry of Health authorised B C G vaccination of 13-year-old schoolchildren in 1953, and Springett[12] has reported the effects of this scheme in Birmingham

Vaccination of schoolchildren began in 1954, and all those reaching 14 years of age in or after March, 1955, should have been included in the scheme, so in 1958 all aged 14 and 15 had been eligible for tuberculin-testing and vaccination, together with almost all aged 16, a large proportion of the 17-year-olds, and a few of those aged 18, but none over that age Each year, of some 15,000–17,000 children who left school, roughly three-quarters received their parents' consent to take part in the scheme, and over 85% of those tuberculin-tested were found negative and were vaccinated In 1954, when vaccination began, there were 231 notifications of tuberculosis in Birmingham in persons aged 10–19 years, the corresponding figures for the next four years were 203, 154, 119, and 143 Children aged 14 were fully covered by the scheme from 1956 onwards, among them there were 19 notifications in 1955, 8 in 1956, and 6 in 1958 Those aged 15 were covered from 1957, and the number of notifications among them fell from 24 in 1955 to 3 in 1958 The reduction in the total notification-rates possibly attribut-

able to the B C G vaccination scheme was estimated to have been 0 5–0 7 per 1000 per year

The value of a B C G scheme in a community depends on the proportion of individuals in it who are already infected at the age when vaccination is offered and the risk of infection after vaccination In the M R C trial (and in others) the incidence of tuberculosis in the observation period was highest in those who were tuberculin-positive on entry This is, of course, not surprising, for tuberculin sensitivity in such circumstances indicates tuberculous disease, even though there are no other observable manifestations of it But in assessing the benefits of vaccination, the spread of the lesions in this already infected group must be taken into account It was estimated that, if all those tuberculin-negative on entry to the M R C trial in 1950–52 at the age of 14 had been vaccinated, the reduction in tuberculosis among the whole group, both tuberculin-negative and tuberculin-positive, would have been 59% in the next five years Since 1950, however, the risk of infection in this country had decreased Sutherland,[13] taking this decrease into account, has estimated the present scope for B C G vaccination in England and Wales Of the tuberculosis notifications in those aged 15–19 in 1958, he estimates that 52% could have been prevented if all who were tuberculin-negative at the age of 14 had then been vaccinated the estimate for 1953 was 60% While decline in exposure to infection continues, the scope for vaccination will also decline B C G vaccination of all uninfected who are now aged 14 would apparently reduce the incidence of tuberculosis in this age-group during the next five years by rather less than half Although the decrease in the *proportion* of cases preventable has been slight in the past five years, the decline in the *numbers* has been great—from about 2950 among those aged 15–19 in 1953, to 1400 in 1958 A stage may fairly soon be reached where mass vaccination of older schoolchildren prevents only a few cases of tuberculosis in young adults, although vaccinations done in the past will, if protection is maintained, still be preventing tuberculosis in those over 20 Springett suggests that communities using B C G vaccination in older schoolchildren should continue the procedure until notification-rates in the non-vaccinated groups are down to 0 1 per 1000 per year

Sutherland has also estimated the reduction in incidence of tuberculosis in those 15–19 years old which resulted from the local-authority vaccination schemes In 1958, for example, the reduction was 241 notifications But the number preventable if all children eligible had been vaccinated was about six times as large Some uninfected children are not vaccinated because their parents do not consent But the blame for the majority of the preventable disease in these young people rests not on the parents but on the local authorities, some of which either began the scheme late and developed it slowly or did not attempt it at all In 1958 only 47% of all children aged 13 in England and Wales were tuberculin-tested and 37% vaccinated If all had been tested the proportion vaccinated would have been about 79%, thus less than half the children who should be vaccinated were being vaccinated It seems deplorable that the careful investigations of the Medical Research Council should not yet have convinced all local authorities that the children for whose health they are responsible can be protected from this serious disease, or that considerations other than medical ones should have prevented them carrying out the recommendations of the Ministry of Health The Ministry, it appears, cannot force a local authority to use B C G vaccine by the scheme they prescribe, yet at the same time they can prevent the vaccine being employed by local authorities in other schemes, even though the particular local circumstances warrant these Thus, a child may be left unprotected either because the local authority will not provide vaccination within the authorised scheme, or because the Ministry will not approve vaccination out of the scheme

The authorised scheme at present includes 13-year-old schoolchildren, and certain relatively small special categories at other ages [14] *Should the age of vaccination be reduced?* Vaccination in the first few weeks of life could protect for an unknown period during infancy, and revaccination would be administratively easy in the early school years, but tuberculous infection of infants is declining rapidly, and it is unlikely that the great effort of attempting to vaccinate all infants throughout the country would be justified by the results Moreover, the incidence of troublesome complications with the present intradermal route is higher in infants than in older children [15] Pollock [16] discussed the advantage of reducing the age from 13 to 10 At this age fewer would already have been infected and more could be protected during the vulnerable years of adolescence But, as he says,[17] " the tuberculin-positive proportion of the 13-year-old age group is diminishing each year [and] the application of a mass vaccination scheme requires to be regularly reviewed as the epidemiological situation changes " Sutherland suggests that a central bureau be established in connection with the official vaccination scheme In this way changes in the tuberculin-sensitivity of children in different parts of the country could be observed and interpreted, and the notified cases of tuberculosis at later ages related to previous tuberculin sensitivity and vaccination Such a scheme has been working successfully in Denmark for several years [18] This central collection of information has much to commend it, and if the eradication of tuberculosis, and not just its " control ", is the policy of the public-health authorities, it should not be administratively irksome But its value would be reduced if the central authority did not have some power to compel local authorities to offer vaccination against tuberculosis At the same time it might be profitable in planning national schemes to abandon the present rigid uniformity and to take into account major local differences in the risks of infection, even between parts of the same administrative unit

Annotations

RABBITS

By the end of 1955 myxomatosis had destroyed over 90% of the rabbits in this country, but even as early as April of that year an attenuated strain of the virus caused extensive infection in Sherwood Forest Since then the less lethal form of the disease has been recognised in most counties of England and Wales, and many people have assumed that this is the natural course of events and that the infection can only persist in the less severe form In Australia Fenner[1] and his colleagues showed that the introduced lethal virus, which was different from our own, was soon replaced by less virulent strains and—which is more important—that after seven epizootics even the original virus killed only about a third of newly caught young wild rabbits In Australia attenuation of the virus thus appears to have favoured the natural selection of genetically resistant rabbits, and myxomatosis can no longer be regarded as of great value in pest-control So far as is known, no such selection has occurred here and British rabbits are no more resistant to the virus than they were before 1954

Differences in the evolution of the disease depend among other things on the complex relationships between virus, host, and vector, and in Australia mosquitoes (which Fenner has likened to flying pins) are the principal vectors Rabbits infected with less virulent virus will survive longer than those infected with a fully virulent strain more mosquitoes will therefore have a more durable source of virus provided that the nodular type of lesion of the attenuated strains remains rich in virus Under these circumstances natural selection will favour such strains, and indeed Fenner et al[2] showed that even when the highly virulent European strain was introduced on a large scale into an already infected area it dominated the peak of the epizootic during the summer but was supplanted by the local attenuated strains within a year Virus which is too attenuated may multiply so poorly that mosquito transmission is impossible, but such strains have not been isolated in the field

In Britain outbreaks of attenuated myxoma infection are probably still increasing, but there is no sign that these strains are supplanting the original lethal agent According to Andrewes et al[3] evolutionary pressure here is more likely to favour fully virulent virus, partly, at least, because of the habits of the chief transmitter *Spilopsyllus cuniculi*, the rabbit flea Fleas will leave a dead animal and spread the infection, but they may not leave it at all or only when there is little virus available to contaminate the proboscis if the animal survives or has a long illness As Marshall and Fenner[4] point out this would, at least for a time, favour dissemination of fully virulent virus It is a platitude that infectious agents which kill all their hosts end by committing suicide, and possibly our present situation, where fully virulent and attenuated strains exist side by side, is a temporary evolutionary compromise. How long it may continue no-one can predict, for much though Fenner and his colleagues have learned about the epidemiology of the Australian disease, we know much less here How the virus persists between outbreaks, and why and how it suddenly reappears in some districts after months or years of absence, we still do not know Possibly the discontinuity of the outbreaks in a population whose individuals have an average life-span of about a year will help to avert virus-resistance in rabbits Even if we escape the Australian epidemiological dilemma, we obviously cannot now count on an enzootic disease such as myxomatosis since it is both unpredictable and uncontrollable as a method of reducing our rapidly increasing numbers of rabbits There was severe damage to farm crops last year, and the activities of the rabbit clearance societies should be greatly increased and much more widely supported

FLUORESCENT RED CELLS

IRRADIATED at a suitable wavelength, many substances of biochemical interest (porphyrins, stercobilin, certain vitamins, and chemotherapeutic agents, to name but a few) either fluoresce spontaneously or can be induced to do so by treatment with fluorescent material Others do not readily combine with these dyes, and a few actively extinguish their fluorescence That hæmoglobin belongs to this last category has been one reason why fluorescence microscopy has never attracted a following among hæmatologists Kosenow[1] outlined the scope of the method in the study of white cells, platelets, and the immature members of the erythrocyte series, but he agreed with earlier observers that the appearance of hæmoglobin in the cell blots out all morphological and chemical detail[2] Werth and others have shown that this transformation is due to active extinction by the hæm moiety of the hæmoglobin molecule[3,4] Apart from occasional fluorocytes—cells which display brief red luminosity among the dark discs of ordinary red cells—the exceptions have been erythrocytes of patients with porphyria and lead poisoning

A year ago Donath and Lengyel,[5] of the Anatomical Institute of the University of Budapest, reported a series of experiments in which they had sought to overcome the fluorescence-extinguishing power of hæmoglobin without seriously damaging the red cells Using various chemicals (such as sodium hypophosphate) they found it comparatively easy to impart fluorescence to the red-cell stroma and thus partly to overcome the blackout effect of hæmoglobin, but neither by introducing such substances nor by altering the ionic state of the hæm iron could they influence the behaviour of hæmoglobin itself This they achieved, however, by treating red cells with hydrogen peroxide before staining or by applying the dye mixed with hydrogen peroxide erythrocytes could then be made to fluoresce vividly both on smears and in wet preparations

This work was taken up by investigators engaged in the study of possible variations in the hæmoglobin molecule in acquired disease Martos and her colleagues[6] found that fixed minimal quantities of fluorescent dye were necessary to induce fluorescence in hæmolysates of given concentrations, and, more surprisingly, that this fixed minimal quantity changed in chronic illnesses They now claim that such pathological states cause a structural change in hæmoglobin, and that this change can be detected by the altered capacity to extinguish fluorescence

after hydrogen-peroxide treatment Similar changes were noted after X-irradiation[7] even after comparatively small doses, and before any other change in the blood-picture (such as lymphopenia), the blackout effect of hæmoglobin on the red cells became more resistant to attenuation by powerful oxidising agents

These preliminary results still require a good deal of experimental support, and, once the experimental facts are established, they will have to be interpreted with caution (The data available at present do not even exclude the possibility that haptoglobulins were partly responsible for the changes described) Even at this early stage, however, the work reminds us that the genetically determined abnormalities of hæmoglobin are not necessarily the only ones, and that, impressive though the advances in hæmoglobin chemistry have been, important gaps still exist When we ascribe hæmoglobinopathies to minute chemical flaws in the globin moiety of hæmoglobin and dismiss the hæm moiety as normal, we should reflect that many of the clinical features (such as those resulting from changes in the oxygen-binding capacity) clearly point to altered function if not to altered structure of hæm Possibly in the experiments reported by the Hungarian workers the hydrogen peroxide led to chemical changes in the globin moiety of hæmoglobin which affected the fluorescence-extinguishing power of hæm The phenomenon could then be analogous in some respects to the change in the congenital hæmoglobinopathies it is certainly just as puzzling

INFANTILE STRUCTURAL SCOLIOSIS

AT one time diagnosis in orthopædics was followed almost automatically by treatment, usually for some gross deformity which needed correction Now, however, because orthopædic disorders are becoming less obvious and gross, knowledge of prognosis or the natural history of the condition is increasingly recognised as an essential preliminary to treatment Many orthopædic conditions are essentially self-curing, and accordingly complicated or expensive or potentially dangerous treatments are contraindicated Notable among such conditions are certain deformities of childhood in which time and growth are likely to correct the deformity—for example, most types of knock-knee and flat-feet, many deformities following fractures of the long bones, and even the gross deformities following an unreduced supracondylar fracture of the humerus

In 1936 Harrenstein[8] described what is now known as infantile scoliosis—that is, scoliosis appearing in early infancy without obvious cause and, in particular, without gross congenital bony anomalies such as wedged vertebræ or fused ribs In 1951 James[9] described 33 cases of infantile idiopathic scoliosis, and James et al[10] have lately described the natural course of the condition in 212 infants first seen below the age of three years In roughly a third (77) of these the scoliosis resolved spontaneously, in the remainder severe and progressive scoliosis developed In the early stages no bony abnormalities were detectable on radiographic investigation, and in 1 child, who died at the age of eleven months, no abnormality could be discovered on either macroscopic or microscopic examination It is still uncertain whether the resolving and progressive curves are basically the same at the beginning If they are, discovery of the cause of resolution might lead to an important advance in our knowledge of the ætiology and treatment of idiopathic scoliosis Meanwhile, there is much to be gained by further study of the natural history of severe deformities, and until this is understood it is wrong to claim that any particular treatment has been successful

SCHOOL PHOBIA

THE syndrome of " school phobia " was first described by Broadwin[1] in 1932, although the term was not coined until nine years later[2] It consists in persistent refusal to attend school, the child remaining at home with the full knowledge of his parents " Truants " behave differently, usually absenting themselves from both school and home Hersov[3] has shown that these two groups differ school refusers are more intelligent, of higher social class, work and behave better at school, are more timid, and have been less frequently separated from their mothers in early childhood The mothers are often over-protective and there is more neurosis in the family School phobics are afraid of separation from their mothers and homes, and Burns,[4] among others, has emphasised that it is this separation-anxiety rather than fear of school that is the underlying problem they are not phobic in the accepted sense, and perhaps, as Davidson[5] has suggested, they would be better called mother-philes than school-phobes—a term which casts an undeserved slur upon the pedagogues While school refusal is usually a symptom of a neurotic disturbance, truancy tends to be associated with delinquency

The number of cases seen in clinics is undoubtedly increasing both in America[6] and in this country[7], but Barber[8] has suggested that, in the Bristol area anyway, the increase reflects greater zeal on the part of school attendance officers, and the National Association for Mental Health after its two 1959 conferences on the subject said that it has no evidence of an overall rise[9] It is very likely that many children now treated as neurotic were previously dealt with as truants, or regarded as having some uncertain organic condition, for in such cases children present characteristically with somatic complaints, especially abdominal pain and nausea on school mornings

The treatment of early cases consists in firm support, and encouragement of mother and child towards a return to school Attempts to force the child only generate greater panic If this fails, psychotherapy, usually of both mother and child, may be required, but a compromise solution, such as allowing the mother to remain with the child at school, may bring about an early return Change of school in itself is useless, for it is not there that the trouble lies, but such a change does provide a fresh start and, in combination with other methods, may help Separation from the parents by residential schooling may be needed, but only after careful judgment and individual treatment, for in the obstinate case the child will immediately abscond Half of Hersov's group of severe cases required inpatient treatment, but on the whole the outlook is good, especially for children below 11 years old of whom 89% attending one clinic were going to school regularly [10], over that age the figure dropped to 36% The "hard core" cases were found to come from the most seriously disturbed families in such cases the school refusal may well be a clinic refusal, and, later on, a work refusal [11] Clearly, the sooner treatment is started the better, and this requires efficient and rapid communication between parents, school, and the many other agencies that may become involved [12]

MEDIASTINAL MASSES

THE situation and radiographic appearance of mediastinal neoplasms, cysts, vascular abnormalities, and glandular enlargements sometimes give a clue to their nature, but short of thoracotomy an exact diagnosis is usually impossible Lyons et al,[13] reviewing a series of 782 mediastinal masses, urge that preliminary investigations additional to chest radiography should nevertheless not be neglected They found that barium swallow and angiocardiography not infrequently helped to establish the diagnosis or to assess operability, and scalene-node biopsy [14] above all proved to be a most valuable ancillary procedure Scalene-node biopsy established the diagnosis in 92% of lymphomas and in 72% of granulomatous lesions with otherwise negative findings, and was also the most fruitful line of investigation in metastatic mediastinal lesions Lyons et al emphasise that for full exploitation of the method technical experience is necessary a point also made by Aikens,[15] who reports useful results with this procedure in various respiratory conditions—especially sarcoidosis and, to a lesser degree, bronchial carcinoma In obscure mediastinal and pulmonary conditions it seems, therefore, that scalene-node biopsy may sometimes avert the necessity for thoracotomy

EXPLORING SUBCORTICAL FUNCTION

WHEN medically intractable epilepsy is to be treated by local cerebral surgery, definition of the precise site where the epileptic discharge originates is important Originally such operations were planned in relation to macroscopic abnormality of the cortex, but when the electrical substrate of epilepsy was recognised its location was assumed to indicate also the site of origin of the clinical seizure On this basis brain tissue showing such activity, even if macroscopically normal, was sometimes removed There is now increasing evidence that, although some relationship between the site of origin of electrical abnormality and epilepsy exists, the correlation is far from complete The search for a spike focus, and the excision of regions where it arises, are therefore now less keenly pursued—though the results are often beneficial

Earl Walker and his colleagues,[16] who have already contributed much to this subject, have reviewed the results of subcortical recording in temporal-lobe epilepsy They note that the absence of surface activity, including that from sphenoidal leads, does not exclude a subcortical temporal focus They also find that, as with surface activity, spontaneous subcortical spike discharges are often unaccompanied by any overt clinical attack and they suggest that these non-ictal discharges seem not to affect the normal functioning of the area, so far as simple tests of mentation can show

Stimulation of deep temporal-lobe structures and basal ganglia suggested that the threshold for excitation of amygdala and hippocampus is relatively low, and that spread of discharge from these areas is wide Confusion and alteration of thought were common, as were visceral, vasomotor, and emotional changes An interesting finding was that stimulation of amygdala, thalamus, and globus pallidus elicited pain in one half of the body The general picture is of visceral and affective responses from a number of sites, including medial temporal, inferior frontal, and thalamic But relatively few stimulations, even of those producing electrical after-discharge, gave rise to clinical features of any sort

INFECTION AT THE HAIRDRESSER'S

MOST men choose their hairdresser for reasons of nearness, cheapness, or cleanliness (Women add other criteria less easily summarised) The "cleanliness" is judged, we would guess, by standards that are basically unconnected with health People dislike the shop which is stuffy or which has a smell to which they are not accustomed They do not care for a floor littered with shorn locks, or sheets which have not been laundered recently With shame they may admit that they avoid the shop whose customers come from another income group (whereas they would share a seat on the omnibus without a thought) They seem to feel that they may "catch something" Yet the evidence that the hairdresser's shop plays any important part in the spread of disease is negligible "Barber's rash" is primarily an eczema, often complicated by staphylococcal infection, and though it can be spread by the use of a common razor or towel, the bacteria more often come from the patient's own nose Moreover, public shaving is a dying custom and many of those who have this disease have never been shaved *Microsporon audouini* was certainly disseminated by the hairdresser, but ringworm due to this fungus is now rare compared with that derived from animals (That it was commoner in boys than girls may have been due to the fact that small girls tended to have their hair cut at home and the close crop of the small boy allowed the fungus easier access to the skin) Any ill-ventilated enclosure encourages the spread of respiratory infections, but the barber's shop cannot be more dangerous than the four-ale bar

An attempt to give some objective value to the assessment of cleanliness in hairdressers' shops has been made in Glasgow [1] Fifty establishments were subjected to thorough inspection and judged by much the same standards as those used for eating-houses, with particular attention to such things as the disinfection of instruments As might be expected, there was wide variation between the shops indeed, almost the only thing they had in common was poor sanitary facilities for the staff Shops patronised entirely by women were on the whole cleaner than those reserved for men, but this is not surprising in every walk of life men wear dirtier clothes and have dirtier habits Many bacteriological examinations of premises and equipment were made, but the difficulty here is that, to be really useful, numerical values must be compared with other numerical values, and one would like to know how the microflora of the hairdresser's shop compares with that of the railway carriage or the doctor's waiting-room The failure to recover ringworm fungi was interesting and encouraging but likewise evokes a further question how common was the disease in Glasgow at the time?

Fastidiousness is generally an aid to hygiene, and people who normally prefer to keep to their own brushes and towels are entitled to demand a high standard of cleanliness in places where such things serve a succession of customers They will therefore welcome the medical attention to these matters which this investigation shows Nevertheless the general notion that hair is rather dirty stuff is now largely irrational, dating perhaps from the days when it nearly always *was* rather dirty On bacteriological examination, clean hair shows few bacteria in it and even fewer that are likely to cause disease

TEAMWORK FOR CLEFT PALATES

THE management of babies with cleft palate has rightly become the concern of a team rather than an individual This enlightened approach, which has been particularly evident in Britain, was demonstrated during the L D S centenary celebrations last July by the choice of subject for the main scientific symposium—namely, Treatment of the Cleft Palate[1] An embryologist, a plastic surgeon, an orthodontist, and an expert in prosthetics outlined an integrated attack in which none could succeed alone No claims for any startling technical advance were made, though some discussion centred on the scope of the early " orthopædic " treatment advocated five years ago by McNeil[2] On this issue one point is clear that no intraoral appliance in early infancy (or later) can conceivably achieve closure of the soft palate—and therefore the operative repair of this vital structure cannot be obviated It was emphasised that patients must be considered as people—" this lesion is a fissure in the palate completely surrounded by a human being " It was imperative that they should not be allowed to reach adult life as vocal, cosmetic, or dental cripples

The surgeon should at the first opportunity give the parents, who may be appalled by their child's deformity, an honest but reassuring outline of the therapeutic plan Two-thirds of palatal clefts are " complete ", involving lip and alveolus, and the stages in these severe cases can broadly be summarised as follows repair of the lip and nasal floor is carried out at 3 months, and repair of the hard and soft palate at 18–24 months, orthodontic supervision (which should be begun soon after birth) can reach the stage of maxillary expansion at 4–6 years, speech therapy (if indicated) should also be begun at about this age, but in a good home this task may be supererogatory Prosthetic treatment often consists in merely replacing an absent lateral incisor, but a few surgical disasters are still seen, and for these (as for the rare cases where primary surgery is impossible) an obturator may sometimes prove startlingly effective in providing clear speech Finally, secondary surgical adjustments to lip, septum, and nose may be indicated and are usually deferred until the patient is 15 or older

At the symposium an issue of particular importance was raised—the operative mortality and its possible relation to the patient's age Strong claims have been made that the palate should be repaired at the first birthday, and in a recently published series[3] the subsequent operative mortality was 3 7% This is at striking variance with the figure given by Fogh Andersen (cited in the same paper), who operated at about the 2nd birthday with a death-rate of 0 6% This comparison offers up-to-date evidence for the view, held in earlier days, that a young baby is not as a rule an acceptable risk for this major procedure While the hazards have been enormously reduced, particularly by modern standards of anæsthesia and general management, they have not yet been eliminated In the opinion of many experienced surgeons sound reasons still exist for deferring operation until the deciduous dentition is complete—and there may be special considerations which justify postponing operation for 3 or 4 years Contrary arguments, based on theories of the developing patterns of speech, carry little weight when set against the cost in lives Perfect speech is an admirable goal, but the death of a child once in every thirty operations is a heavy price As the published results of Fraser and McCredie,[4] Davies and Danks,[5] and others have shown, the death-rate ought not to exceed 0 5%—and " should be nil "

DIAGNOSIS OF MULTIPLE PREGNANCIES

AN interesting report on the use of the electro-encephalogram in the diagnosis of multiple pregnancy by identification of fœtal cardiac activity has appeared in the United States Using a standard eight-channel Grass model III electroencephalograph, Novotny et al[6] studied 321 tracings from 295 patients They found that the 28th to 36th week of pregnancy was the most difficult time for demonstrating fœtal heart activity, the best results being obtained between the 20th and the 28th week In 81% of cases single or multiple pregnancy was correctly diagnosed, or fœtal death confirmed, and in the 20th to 28th weeks the proportion was 90% Difficulties were encountered as a result of excessive maternal muscle artefact, excessive fœtal activity, poor cooperation by the patient, failure to empty the bladder, or maternal tachycardia Accordingly 20 tracings were technically unsatisfactory for interpretation, while in 38 others either the fœtal heart activity was not demonstrated although the fœtus was alive or only one heart was revealed when two or more fœtuses were present

As an alternative to the positive demonstration of multiple pregnancy by X-rays, this method cannot yet be accepted completely Because of the dangers to the undiagnosed second twin during delivery, the method of diagnosis should be thoroughly reliable, and the likelihood of error with the electroencephalographic method *is* not outweighed by the very early diagnosis which may be possible (twins were correctly diagnosed at 16 weeks and triplets at 20 weeks, while an X-ray at 24 weeks in the same case of triplets was still inconclusive) The great advantage of this method lies in the avoidance of radiation hazards, and if further experience were to increase its accuracy it might prove a valuable additional means of investigation

THE MARRIED MENTAL DEFECTIVE

A FOLLOW-UP STUDY

C H Shaw
M D Lond , D P H , D P A
DEPUTY MEDICAL OFFICER OF HEALTH

Catherine H Wright
M B Glasg , D P H
ASSISTANT MATERNITY AND CHILD WELFARE MEDICAL OFFICER

SHEFFIELD

Even before the Royal Commission's report, public opinion was fast moving away from the ideas current at the beginning of this century when mental-deficiency legislation was being formulated Though prohibition of marriage was dropped from the original Bill, under the Mental Deficiency Act of 1913 many mental defectives were segregated in colonies for the years when they were most likely to bear children As recently as 1949 the Ministry of Health expressed the opinion that mental defectives were generally unfit for the responsibility of marriage and of parenthood, and that, even if they were able to conform to normal social requirements in sheltered conditions in the community, they were rarely able to stand the strain of bringing up children and managing a household

Today some well-informed people are undoubtedly seriously disturbed by the possible social and genetic consequences of community care Detailed studies of intelligence levels among the children of mental defectives are conflicting (Penrose 1938, Brandon 1957) Little attention has been paid to the social performance of families in the community, though several follow-up inquiries (Ainsworth et al 1945, Mickelson 1947, Hartzler 1953, Wolfson 1956) throw some light on the American scene The object of the present investigation was to choose a random sample of the married defectives in Sheffield and follow them up systematically to see what success they had made of marriage.

METHOD

We selected the cases by going through the departmental records of all mental defectives ascertained since 1915 Of the 2877 records scrutinised 640 referred to patients in mental-deficiency hospitals, and 1293 to mental defectives under statutory supervision The remaining 944 had been discharged from statutory supervision Defectives are usually discharged from statutory supervision when they have shown themselves capable of leading a stable life within the community

Marriages listed for investigation were those recorded on the case-notes These numbered 120 men and 122 women including ten instances in which ascertained defectives had married each other Other marriages may have occurred after discharge from supervision, but we investigated only those given in the case-notes

THE SPOUSES

Of the original 242 defectives 45 (19%) are untraced 19 of those untraced are known to have moved from Sheffield, though some may have returned unknown to the department. No attempt was made to follow up any patient outside the city boundary, because there is a danger of rediscovering the less satisfactory families and overlooking those who have merged successfully in the community Searching for families through intermediary authorities adds a further element of uncertainty as to whether the people traced are representative of those originally selected Eventually 197 (81%) people were traced Of these 98 were still under statutory supervision (including 13 in institutions) while 99 had been discharged An inquiry was made and a pro-forma completed by the district health visitor or mental welfare officer on the basis of an interview or from previous knowledge Opinions have occasionally been modified in the light of further information from other departments or from voluntary bodies

Intelligence level

The intelligence quotient of 122 of the defectives in the survey was recorded In 93 (76%) the I Q distribution lay between fifty and sixty-nine, 13 (11%) were above this range and 16 (13%) below There were proportionately more men with I Q s over sixty-five, probably because they were ascertained as mental defectives on account of behaviour difficulties at school or other indiscretions, despite a moderate level of intelligence.

Size of Family

The mean age of marriage among the men was 22 2 years compared with 25 2 years among the women defectives In the country as a whole men marry 3 years later than women Live births, however, were 50% greater than the norm for women married at the same age and for the same length of time The birth-rate was also appreciably above that in families of unskilled workers (Registrar General 1959)

Infant Mortality

Information about infant deaths was often incomplete and infant mortality has only been assessed since July, 1944 Nevertheless 26 infants are known to have died, equivalent to an infant-mortality rate of about 73 per 1000 live births This is in line with earlier findings (Departmental Committee on Sterilisation 1934, Juda 1934)

Employment

Of the mentally defective husbands 34 were in unskilled occupations but 24 were doing semiskilled or possibly even skilled work. There was not enough information to classify the employment of 13 5 husbands were temporarily unemployed, 13 were chronically unemployed, 6 were in mental-deficiency hospitals, and 5 were in prison (i e , 29% were not in employment) Of the mentally defective wives only 14 were employed outside the home.

9 of the men were registered as disabled persons, and of these 4 were unemployed. 2 others, who were among the chronically unemployed, were on the blind register

Criminal Record

5 husbands were serving a prison sentence and a further 7 had served previous terms of imprisonment The offences included robbery with violence (1), larceny (4), child neglect (2) Another 30 had been before the courts for stealing, sexual offences, or minor misdemeanours 11 of the mentally defective wives had appeared before the courts for offences such as prostitution and theft but only 1 had served a prison sentence.

Broken Marriages

38 divorces or permanent separations were met in the survey, equivalent to 20% of the total families traced 9 marriages were obviously unsatisfactory even to the outsider Nevertheless most of the marriages seemed to be reasonably happy and stable even when the families presented problems to others

Child Care

34 families were known to the National Society for the Prevention of Cruelty to Children, and the children's department had been concerned with a further 11 families over reports of neglect or other circumstances that led to the children being placed in the care of the local authority for several months or longer These 45 families were almost a third of the families who had one or more children—a disturbingly high proportion According to departmental records the childhood background of the defective parent was considered unsatisfactory in 28 of 41 neglected families (68%) compared with 56 of the remaining 126 families (44%)

THE SECOND GENERATION

Of the 377 children 46 were unsuitable for education in an ordinary school, or were so retarded that it was unlikely that they would prove suitable This is equivalent to 10 6% of live births or 12 2% of children surviving the first year of life

6 children were in mental-deficiency hospitals, 26 were in special (E S N) schools, 9 were at occupation centres, 5 were retarded children under school-age We saw all the pre-school children personally and carried out an intelligence test where possible

Many head teachers are very tolerant of backward children and it seemed that there might be other retarded children from the survey families whose names were not put forward for transfer to a special school Evidence is available from the results of routine group intelligence tests given at ordinary schools as part of the secondary selection procedure Records were traced of 57 (76%) of these children in the survey families 59% of the test scores fell between eighty and one hundred , 12% were above this range and 29% below Only 3 children had scored under seventy in both of two I Q tests, which suggests that few mentally retarded children had been overlooked

Among the survey group 11 6% of schoolchildren were attending special (E S N) schools, this percentage is about 17 times higher than for the Sheffield school population as a whole The proportion of children of compulsory school-age who had been reported as ineducable (5 6%) was also 17 times higher Of the 23 survey children attending a special school for the educationally subnormal, only 2 had an I Q above seventy (Terman-Merrill)

SUCCESSFUL AND LESS SUCCESSFUL

26 families could be described as problem families in the sense that they had presented problems to several departments of the corporation and to other social agencies The home environment seriously jeopardised the mental and physical development of the children In 15 (58%) one or more children had to be removed from the care of the parents, though the family was not necessarily split up at the time of the survey Several other families undoubtedly would have fallen into the category of " problem family " but for the fact that at the time of the survey the parents had separated and the family had ceased to exist as an entity Of 10 families where both man and wife had been ascertained defectives 5 were regarded as problem families of the other 5 marriages only 2 could be considered satisfactory, 1 of these being a childless couple

40 families out of 90 (44%) where the man was defective and 38 families out of 87 (44%) where the woman was defective seemed to be living reasonably happy and normal lives They were self-supporting within the community and not a special problem to any social service Many families in the survey showed unsatisfactory features such as poor child care, slovenliness, or obvious signs of marital disharmony Sheridan (1956) has observed that temperamentally stable mentally defective mothers can cope with their households fairly well while they have only one or two children, but when their family responsibilities outgrow their capacity they become overwhelmed Our own experience supports this view Excluding the 38 marriages where the husband and wife had separated, there were 92 marriages childless or with one or two children, and 57 marriages with three children or more Of the small families 59 (64%) appeared to be quite successful from the point of view of social adaptation, whereas among the larger families only 22 (39%) were satisfactory Of the 15 families where husband or wife had an I Q of under fifty only 2 were in the satisfactory group, and there was reason to doubt the validity of their I Q assessment

Discussion

The picture that emerges is not clear-cut Young people of low ability are destined either for success or failure, and, if only there were some sure method of differentiation, it would be easy for the community to arrange for a psychiatric assessment and help them in a rational manner In fact, however, this is far from possible Some of those with the most depressing record suddenly achieve stability, and settle down in a way that is a credit to them With I Q s of fifty or above there seems no close correlation between intelligence level and social adaptability, though we doubt whether a mother with an I Q of under fifty-five or so is really mentally capable of raising a family satisfactorily Even here, however, where there is only one, or possibly two, children, the standard of care may be adequate The impression of the visitors was that mental defectives tend to choose, or be chosen by, a partner of about their own intelligence level Undoubtedly, however, that little extra ability, if it is there, can make all the difference in enabling a family to manage its affairs in a way acceptable to the community

Though families exist where all members are obviously mentally subnormal, usually they tend to show ranges of ability not so very different from the average The size of the families is larger than the average, though the additional births are to some extent balanced by the number of infant deaths The employment record of the defectives was fairly good, despite a hard core who contributed little or nothing to the support of themselves or their families The proportion of men who had fallen foul of the police was rather high Most had been dealt with under the normal penal procedure, though 13 appear to have been admitted to an institution as a direct result of the offence In the survey a fairly high proportion of the children found neglected were the offspring of defective parents who themselves had an unsatisfactory upbringing

The reasons why some families have failed may appear only too clear, but an explanation of the successes must take account of social adaptability and tolerance Similarly, the community must be tolerant and adaptable However comprehensive the mental health services, there will always be those who do not conform to recognised codes of behaviour Patience and forbearance will be necessary if the mentally handicapped are to live within the community in peaceful coexistence

This follow-up study could not have been carried out without the health visitors and mental welfare officers who undertook the field work Much confidential information has been provided by social agencies and by other departments of the local authority, but the opinions expressed are our own and do not necessarily reflect the views of the agencies consulted or the Sheffield City Council

THE AMERICAN SCENE

SOME striking facts about medical developments in the United States are given by Dr **WILLARD C. RAPPLEYE** in his report on Dec. 1 as president of the Josiah Macy, Jr., Foundation.[1]

Support for Research

He begins by speaking of the " enormous expansion of research funds now available from governmental and other sources ". For the National Institutes of Health at Bethesda, the U.S. Congress voted about 400 million dollars, or nearly 50 million dollars more than the institutes asked for. In authorising this increase of 36% over the previous year's expenditure President Eisenhower expressed concern lest it should actually " lower the quality of the projects supported ", divert into research too much of the man-power and other resources needed for " equally vital teaching and medical practice ", or make medical research and training more dependent on federal funds. But large sums are at present collected by voluntary agencies: for example, last year the American Cancer Society raised nearly 30 million dollars, the National Tuberculosis Association nearly 26 million, the American Heart Association over 22 million. With smaller incomes, the Muscular Dystrophy Association raised nearly $5^1/_2$ million dollars, the National Association for Mental Health 5 million, and the Arthritis and Rheumatism Foundation 3 million.

Dr. Rappleye refers to the way in which the control, direction, and utilisation of research-workers is being detached from the educational institutions, so that many investigators are becoming " journeymen scientists ", often with little or no responsibility for teaching or institutional services.

> " Comments are increasing regarding the large numbers of young scientists who are employed on short term research or traineeship funds whose future livelihoods and careers are uncertain. Hundreds of these young men and women are becoming worried about their futures which is being reflected in reluctance of others to enter the field so largely dependent on governmental, foundation, industrial or other impermanent funds."

Medical Education

The amount of money spent on medical education represents only 1% of the total expenditure for health services (and it includes numerous hospital services which should partly be supported from non-educational sources).

> " One fortieth of one per cent of corporate profits of American industry before taxes would be sufficient to cover the teaching deficits of the 85 medical schools. Private practice and medical insurance fees are helping in a number of instances to maintain the clinical staff. More financial support from various sources is urgently needed if the obligations of medical education as the essential feature of an adequate health service of the nation are to be maintained."

Though usually the university is regarded as responsible for the preparation of doctors, a substantial part of the clinical education of medical students is often provided in non-university hospitals. Moreover, over three-quarters of the 12,469 approved internships and over half the 31,818 residencies are in such hospitals.

> " Fortunately, many of the non-university hospitals now have modern laboratory and other facilities and professional staffs of excellence and good training, some of them on a full-time basis, who would be able to give a high quality of instruction to medical students, to house staffs and local practicing physicians if given the opportunity and incentive. A large reservoir of potential training opportunities exists which might be utilized through proper educational leadership and guidance."

" In view of the avalanche of new knowledge and the masking of scientific developments in part behind commercial exploitation the problems of keeping a physician in practice up-to-date presents a major challenge to the profession, hospitals and medical schools." New and vigorous plans for postgraduate education must be made if the public are to get the benefit of scientific advances. This Dr. Rappleye describes as a " crucial aspect of modern medical care ". Writing of the possible incentives to practitioners to continue their education, he says that " the idea of a periodic re-examination of physicians is again under review ".

Meanwhile there is the still growing problem of absorbing graduates of foreign medical schools: last year there were 9254 foreign-trained interns and residents in 821 hospitals.

> A quarter of these were in New York, where " in the municipal hospital system eleven of the institutions have not a single graduate of an American school ". Most of the foreign group in New York City come from the Philippines (1598), Turkey (587), and Mexico (500). There are now about 2200 Americans studying medicine abroad—usually because they cannot get into an American school. Yet " some of our own institutions have not enough acceptable applicants to fill their classes, sometimes because of geographical restrictions on students in certain state medical schools."

The Surgeon General's Consultant Group on Medical Education has recommended an increase in the annual output of American medical schools by 3600 (at present it is about 6800), and has proposed the creation of 20–24 new schools.

Prepayment for Illness

Discussing the continuing difficulties of the Blue Cross and Blue Shield schemes under which so many Americans insure against illness, Dr. Rappleye says:

> " The challenge immediately ahead is the extent to which premiums on a voluntary basis can meet the costs of expanding hospital services. There is some evidence to indicate that the premium income on a voluntary basis is not likely to rise much above one-third of the total costs of hospital care in the aggregate. That this figure may be somewhere near correct is illustrated by the recent decision of Canada to provide complete hospital service for the entire population on the basis of a $33^1/_3$ per cent contribution from the individual through pay-roll deductions or other devices. It is of interest that Austria has just adopted the same formula."

Proposals have recently been made by the labour unions of New York to organise their own chain of hospitals and medical services, and the New York County Medical Society has offered to cooperate in such a plan. In Detroit a Community Health Association, sponsored by the United Automobile Workers Union, will shortly be launched. The American Federation of Labour/Congress of Industrial Organisations are now in favour of grants to medical and dental schools not only for equipment and plant but in defraying operating costs. " They continue to recommend the pre-payment plans for consumer-controlled health service plans.

" Younging " of the Population

A new set of problems, Dr. Rappleye says, is confronting the country and medical services through the " younging " as distinguished from the " ageing " of the population. The number of people under 20 years of age will reach 90 million, or 40% of the population, by 1970.

> " An interesting prediction is that by 1970 those of 65 years of age or older (roughly 21,000,000) and those below 20 years

---

[1] The Foundation's address is 16, West 36th Street, New York 36.

of age (roughly 90,000,000) will represent over 50 per cent of the entire population of the country It is obvious that those between the ages of 20 and 65 will be bearing over one-half the economic and certain other responsibilities of the nation "

Medicine and the Law

Delusions or Cruelty ?

A HUSBAND petitioned for divorce on the ground of his wife's cruelty The essence of his case was that from 1954 onwards the wife persistently made false and baseless accusations against him that he was carrying on with other women, and had nagged him on this theme incessantly, for hours at a time

Early in 1955 the wife, who was then about 35 years of age, was seen by Dr J G Hamilton, consultant psychiatrist at the Bethlem Royal Hospital On March 12, 1955, the wife was admitted to that hospital, and remained there until May 28, 1955 She then returned to live with the husband She soon renewed her accusations, suggesting that her husband had been carrying on with other women while she was in hospital In October, 1955, she was again seen by Dr Hamilton She then admitted that some of her accusations against her husband were false, and that she knew they were false when she made them She said that some of the things she had said to her husband had been said in order to trick him

Dr Hamilton gave evidence that, in his opinion, the wife was paranoic, and suffered from delusions, she was never certified and he thought it was improbable that she was ever certifiable He said that she sincerely believed that her husband had affairs with other women, and, despite the fact that she had admitted that some of her accusations were untrue—which was exceptional in such cases—he did not consider that that was enough to outweigh the other reasons for saying that she was deluded When she made these accusations against her husband, she knew the nature and quality of her acts, in that she knew she was accusing her husband of unfaithfulness, but she did not know that what she did was wrong Indeed, she believed that what she did was right She felt that she was a wronged person who had a great grievance and that it was proper for her, believing that her husband was being unfaithful to her, to say so and to act as she did The wife crosspetitioned on the ground of cruelty

Mr Justice PHILLIMORE said that with regard to the husband's charge of cruelty and the answer which had been put forward, there was a presumption that a person was sane so as to be legally responsible for his or her acts The burden of proof was on the wife to prove that, by reason of her state of mind, she either did not know what she was doing or did not know that she was doing what was wrong If she discharged that burden of proof, she could not be held guilty of cruelty It was quite possible that in the autumn of 1954 and, indeed, until her discharge from hospital in May, 1955, she did not know that in making these charges against her husband she was doing what was wrong When, however, she recanted, and admitted that she knew that some of her accusations were false and that some of the things she had said had been said with the object of tricking her husband, it was impossible to hold that thereafter she was not legally responsible for her conduct Her continued accusations therefore amounted to legal cruelty The husband was accordingly granted a decree *nisi* As the wife had also made out her crosscharge of cruelty against the husband, she, too, was granted a decree *nisi*

In England Now

A Running Commentary by Peripatetic Correspondents

I BELIEVE I have at last found a valid use for the drug-firm circulars on antibiotics To make my point I must describe a scene which is continuously repeated throughout the country

Seven of us are seated in the board-room of the Peripheral Regional Hospital Board to select the best candidate for the post of consultant omphalologist to the Central Group of Hospitals We have seen six excellent candidates, all with the correct qualifications (M D , M R C P , F F O), each at an appropriate stage in his career Dr F has been eliminated at the first round because he made an ass of himself at interview he had not only failed to visit the hospitals, he was also completely unaware that the professor on the committee had written a monograph on omphalomancy

The chairman now goes round the table for the second time, asking for two names, please, in order of preference It is immediately clear that we are going to have a long session, for there are three first votes for Dr A and three for Dr B This, mind you, is hardly surprising Dr A —the local boy, no genius but a sound chap—has collected the first votes of the three local members Dr B —the bright boy from the metropolis, with strings of publications and eulogistic references from Harley Street—has the votes of the three others The Chairman has not revealed his hand The pro-A faction (" We cannot be sure that this man B would fit in with local conditions ") is adamant, and the pro-B element (" Our job, Mr Chairman, is to appoint the best man ") is equally immovable The argument is becoming heated it looks like an impasse

It is suddenly noticed, however, that all six second votes have gone to Dr C , who is neither metropolitan nor local, who has spent half his time in teaching hospitals and half in regional hospitals, who has a wife and two children, who has written just three articles, and who has a pleasant personality " I liked that man," says the Chairman, " I thought he interviewed well " The factions dissolve, all agree to support Dr C He is brought in and, somewhat to his surprise, offered the job In point of fact—and less surprisingly—he will do it very well

The moral ? Clearly, Dr C has shown " broad-spectrum acceptability " Dr A and Dr B should have spent more time over breakfast, reading the literature instead of just sorting out the blotters

* * *

Unlike another peripatetic correspondent, I have never felt so close to my dustmen as all that Indeed, it wasn't until it cropped up in the public-health course that I realised how this particular face (of Britain, I mean, not the dustman) was changing Now not only have our City Fathers equipped themselves with end-loading gravity-packers, but so have the R D C down the road But, however much they may enchant the kids (and me) by sticking their tails up in the air, I still can't see how they're emptied Do they stand on their heads or their tails, or are the contents so densely packed that some unfortunate dustman—perhaps dignified by the status of " disimpactor "—has to dig it all out with a shovel ?

* * *

In Service medicine you meet some interesting symptom-complexes in the different age-groups

The *under-twenties*, with a string of symptoms, any two of which are incompatible with life, linked with rosy cheeks, a horse-like appetite, football twice a week, and dancing every third night till 3 A M , present the unusual combination of desperate illness in a healthy body Unaccustomed to sickness the mild symptoms of a cold are resented as a gross departure from normal The giddiness induced by a slight pyrexia is regarded as impending dissolution and the dysphagia of swollen tonsils as acute diphtheria or worse This age-group is highly suspicious of older men (of from 21 up), and you must view their symptoms in the same grave light as they do

The *twenties to twenty-fives* form an interesting subgroup The main morbidity here is love, Yogi, surrealism, and a desire to get away from it all The mortality is nil and they improve amazingly in the warmer summer weather Consultations in this group are somewhat one-sided as the patient does most of the talking

The *twenty-fives to thirties* are connoisseurs of trivia The slight distemper in the temple following guest night is not looked on as divine retribution, but as an early sign of brain tumour which should be investigated at Queen Square at once The slight metatarsal ache following the tango, “ but never the foxtrot doctor ”, is expected to bring a posse of leading London orthopods at a sharp trot.

For those from *thirty upwards* any form of sickness is out of the question The subject with a wife, children, a house, insurance, and a car (none of which he can afford) is only concerned with the struggle for survival Surgery must, as it were, be done on the run, and he is only brought to his knees by some catastrophe like mesenteric gangrene

* * *

Since I left the National Health Service and joined the medical department of a large pharmaceutical organisation, I have had many opportunities to compare and contrast these two ways of life

For a start, it is a great relief to find that I am no longer part of the registrar problem, and I hope that the world of commerce will prove less uncertain for me than the clinical rat race

The material benefits are obvious The work is light and most remunerative Until the past few months I had not had regular Saturday mornings off since I went to kindergarten at the age of five, and to have every Saturday morning to myself is indescribable luxury I no longer find that medical emergencies clash with social engagements, though, perhaps surprisingly, my plans still often have to be altered, for the business executive always changes all his arrangements at least once, at the last moment

It is a pleasure to eat and drink in the style to which one would like to be accustomed, and memories of dreary and monotonous hospital food are soon forgotten as one becomes used to excellent and leisurely meals eaten in the company's interest, and at its expense

I have a large and reasonably quiet office, and a private secretary who works for me alone, instead of part share in an overworked, underpaid, though invariably good-tempered and efficient, medical secretary

I had expected to find the efficiency of commerce a change from the National Health Service's maladministration, but in this context my old and new jobs are strictly comparable I really believe that in business there is more of penny-wisdom and pound (or thousand-pound)-foolishness, than in the N H S itself

There remains only one thing to add—the work is extremely interesting, perhaps even useful, and has rather less routine in it than any other job I have done

Incidentally, in spite of all this plushiness, we are still served, at four in the afternoon and eleven in the morning, with the same terrible tea and appalling coffee

* * *

She was a farmer's wife from the Fens, accustomed to good food and good living, and very free to express her thanks in the medium she knew best Fortunately when she developed secondaries from breast cancer they responded to hormone therapy Stilbœstrol did the trick and the years seemed to roll away as she lost her pain and regained her vitality Being a mere male I naturally took the deluge of eggs which she presented to me as a tribute to the profession Perhaps I should have known better

The sad day came when stilbœstrol lost its magic In despair I turned to testosterone The pain went but so did the harvest of eggs I found that Sister was getting them

Letters to the Editor

CASUALTIES AND CASUALS

SIR,—The work underlying Dr Fry's article of Jan 16 prompts me to express warm approval As chairman of a committee planning a new teaching hospital I have noticed more than once the different interpretations which various members of my committee place upon the word “ casualty ” Some come to their first consideration of the planning of a hospital casualty department with memories of casualty-clearing stations, casualty lists, and the like In fact they conform with Dr Fry's observation that the word “ casualty ” implies “ an accident or a serious or fatal event ” In an attempt to clarify this semantic confusion I have described a hospital casualty department as an “ accident and emergency department ” An intractable epistaxis occurring when the family doctor is on his round and unavailable, an attack of renal colic when at work, a foreign body lodged in a small child's nose or ear, or a generalised convulsion in a child *is* an emergency from the patient's or parent's point of view, and no reclassification by doctors or administrators will prevent such cases presenting themselves with a sense of urgency at the hospital The fact that their National Health Service family doctor might, if available, in many instances be able to deal with the situation does not detract from that sense of urgency In any discussion of this subject agreement on this point is fundamental If we are not to receive them in casualty in future what are we to do?

One alternative, as Dr Fry seems to suggest in his discussion, is that some sort of selection of cases should be enforced But by whom? Not by the porter on the door, surely only by the casualty officer, and that is what is happening now

The issue is perhaps only confused when Dr Fry writes “ agreement has not yet been reached on the part that the casualty department should play ”, and three lines (and one sentence) later “ In my own series only 60% of cases were ‘ casualty ’ problems ” Does he mean that only 60% were cases of “ accident or a serious or fatal event ”, or does he mean that only 60% were found, after careful examination by the casualty officer, to fit in to his present idea of what a casualty department should cater for? And anyway why “ *only* 60% ”? The figure is an index of the patients' diagnostic ability of their own urgent troubles and seems to me to be pretty good I wish I could believe I could be 60% right in such circumstances

From the medico-administrative or planning aspect of the casualty department of the future, three factors seem to be important but may be difficult to assess

First, whether in any given neighbourhood the total number and rough distribution among diagnoses, ages, and sexes is likely to alter significantly Dr Fry's record of nearly double the number of new patients in 1958 as compared with 1946 is of interest here

Secondly, whether the trend of any such change warrants a change in the selection of the persons (the consultants) in ultimate charge of casualty departments For instance, would an orthopædic surgeon be peculiarly appropriate to deal with Dr Fry's series of 2935 new patients in which 272 (9%) were fractures The remainder (91%), we should notice included sepsis, poisonings, various medical problems, soft-tissue trauma, burns, psychiatric problems, &c

Third, whether we can anticipate any change in the pattern of general practice (group practice, health centres) which will cater for the 30% of cases immediately discharged and the 11% referred to their general practitioner

I think that we need not agree with Dr Fry that " the present-day casualty department has no specific function " The patients who, as taxpayers, own it and pay for it evidently think it has If we disagree with them and agree with Dr Fry that the department is misused or abused it is up to us to suggest a remedy Dr Fry is probably wise to exclude such suggestions from his article

In analysing the " referment " of these cases Dr Fry raised another cogent point Should a casualty department confine itself to first-aid and sorting? There are figures showing the distribution of the arrival of casualties over the 24 hours and from a study of these we have concluded that if the personnel is to be sufficient to cope really promptly and effectively with the " peaks " of accidents and " genuine " emergencies, there will be many idle hands in the department if no appointments for 2nd and 3rd attendances are given in the casualty department, if, in other words, referral is 100%

It would seem sensible to re-define our casualty departments as " accident, emergency, and dressing-stations " and plan along these lines

We should all feel indebted to Dr Fry for his meticulous record-keeping and for his realistic appreciation of the difficulties and responsibilities of those in charge of a hospital's casualty department His excellent paper will provide a basis for intelligent planning, and perhaps a challenge to revise the accepted ideas, if such there be, on junior and consultant staffing of casualty departments

London, W 1 A DOYNE BELL

TREATMENT OF ADVANCED CARCINOMA OF THE BREAST BY OOPHORECTOMY AND PREDNISONE

SIR,—The paper by Dr Brinkley and Dr Pillers (Jan 16) encourages us to place on record our experience with a similar regime at this hospital Our series was started in June, 1956, and totals 46 cases To date we have withheld publication in view of the small number of patients involved, the difficulty in assessing results, and the relatively short follow-up (three years and seven months)

We have found the age, menopausal status, and tumour-cell type to be of no help in predicting the outcome in any given case An attempt to assess the degree of possible adrenal suppression has been made in all cases by serial estimations of urinary ketosteroid and œstrogen excretion levels This has been a laborious procedure So far as we can judge the fall in these levels bears no relation to the clinical results, that is to say, in some cases on whom a satisfactory remission has been obtained the levels of both remained within low normal limits

The presence or absence of metastases in the ovaries also bears no relation to the outcome of the case It has seemed to us desirable in selecting cases for oophorectomy to extend the upper age limit certainly to 65 years, and possibly later in a few others

We have found it easier in most cases to demonstrate arrest of progress of metastases rather than objective evidence of regression In a few patients large ulcerative lesions of the chest wall have completely healed and in others bony consolidation of deposits and regression of pulmonary lesions has definitely occurred Symptomatic relief has, however, been common

In this series we have not noticed any increased tendency to the formation of ascites, pleural effusion, or œdema of the arm as might have been expected with steroid therapy, rather in fact some patients who had required frequent chest aspirations of large pleural effusions for their comfort have ceased to require this procedure completely

There are some disadvantages to this therapeutic programme In the series there was one case of sudden death from massive hæmorrhage from an acute peptic ulcer and in one case not included in the series death occurred following perforation of a peptic ulcer We have endeavoured to exclude patients with past histories of peptic ulceration or accepted them for treatment only after barium-meal examination In all cases it has been our practice to prescribe routine alkali therapy with the prednisone We have also excluded patients with active or only recently quiescent tuberculous lesions It must be recognised that patients with associated diabetes mellitus present considerable therapeutic problems as a result of steroid therapy

It is necessary to warn practitioners against the dangers of sudden withdrawal of the prednisone in patients who may develop an emergency condition

In our 46 cases, 25 are now dead, 10 surviving less than six months, 8 obtained arrest of their disease for periods in excess of twelve months, 4 for two years and 2 for two-and-a-half years It might be noted here that in 4 patients coming to necropsy when particular attention was paid to the adrenal glands, although there appeared to have been some reduction in their overall mass, no histological change had occurred

Among the survivors still under treatment, 1 patient is alive and well after three years and seven months (she had a large fungating local recurrence in the chest wall, complicated by severe secondary hæmorrhages from the surface of the ulcer, which failed to respond to any other form of treatment) 1 patient is alive and well after three years, 1 at two-and-a-half years and 5 after twelve months 6 patients have survived more than six months

We feel that one must assess benefit not only by length of survival but also by the quality of the life lived by the patients in the interval before death Even in some of our disappointing cases there is no doubt in our minds that distressing symptoms have been considerably ameliorated

We feel that this regime is a valuable approach to the problem of the patient with widespread metastatic breast cancer when the only alternatives are adrenalectomy, hypophysectomy, or pituitary destruction These are big undertakings, to the patient and surgeon alike, for on the one hand they are not without hazard and on the other, improvement cannot be promised with certainty in any given case

It may suffice to say that since the evolution of this line of therapy bilateral adrenalectomy or hypophysectomy has been a very infrequent procedure at this hospital

We are grateful to Dr Cameron, of our biochemistry department, for his help with the endocrine estimations

A CENTRAL LABORATORY FOR OCCASIONAL INVESTIGATIONS

SIR,—I support Dr Hughes-Davis (Jan 2) in his suggestion for reference laboratories for occasional investigations, requests being referred by a pathologist

In addition I should welcome contact with a special laboratory under the control of the National Health Service where one could obtain an occasional check of any of the more unsatisfactory routine estimations—e g, serum uric acid, diastase, high bilirubins A specialist laboratory should attract the necessary calibre of trained biochemists if adequate finances were available

We now regularly use the freeze-dried serum prepared by arrangement with the Association of Clinical Pathologists, &c, but this only, at present, allows the extra check of seven of the more simple *estimations*

PHYLLIS DAGNALL

INDUCTION OF ANÆSTHESIA IN YOUNG CHILDREN

SIR,—Dr Hodges' thoughtful article (Jan 9) is of interest to all who have the handling of children at heart The difficulty in all this work is to devise an absolute standard of behaviour pattern Doughty[1] first drew attention to this need, and he has done much work since Using a similar classification to his I did a controlled series of 100 cases, comparing premedication with atropine only, with a methylpentynol/hyoscine mixture given by mouth A summary of my results was

Reaction	*Premedication* *Atropine only*	 *Methylpentynol/hyoscine*
Smiled	5	12
Impassive	18	26
Winced	16	2
Cried	11	10
Total	50	50

All cases were induced with intravenous thiopentone

I still feel that we should help the "self-controlled but guarded" cases of Dr Hodges, provided this can be done with safety, and for this purpose I still find the methylpentynol/hyoscine mixture valuable

Recent correspondence in the *Medical Journal of Australia* [2–5] again raised the matter of the incidence of vomiting during induction after premedication with methylpentynol in the form of 'Oblivon' elixir

Rendell,[6] in the first article on the clinical use of methylpentynol, did state "in about a tenth of the cases induction was delayed by vomiting" It is unfortunate that this statement has been copied many times, including in the new textbook on anæsthetics by Wylie and Churchill-Davidson, because on closer reference to Rendell's article it is stated that "though normally premedication was given 1 hour before operation, half to 2 hours or more proved satisfactory"

In my original article,[7] in which I quote from over 500 cases, I stated that " no difficulty from vomiting on induction has been observed. I think the difference in my series is due to the fact that the methylpentynol had been given at least 1 hour before induction"

I R. McDonald stated[3] that he passed a Ryle's tube on 4 successive cases premedicated with this drug and that the minimum volume aspirated was 8 oz (230 ml)

This obviously needed verification. During routine tonsil lists I therefore passed a small plastic œsophageal tube under direct vision after the patient had been induced and was on the table with the Boyle-Davis gag in position The presence of the tube in the stomach was confirmed by auscultation over the epigastrium. The following were my results

Age (yr)	*Premedication* *Elixir oblivon (drachms)*	 *Hyoscine (gr)*	*Time given*	*Time of aspiration*	*Volume*
10	4	1/100	8 45	10 15	1 ml
3	2	1/150	8 45	10 15	nil
7	3	1/100	8 45	10 45	nil
7	3	1/100	9 0	11 10	nil
6	3	1/100	9 15	11 30	nil
12	4	1/100	8 30	10·0	10 ml
6	3	1/150	8·45	10 15	nil
5	2	1/150	9·0	10 40	1 ml

In no case was the stomach aspirated less than $1^1/_2$ hours after the premedication this I am sure is the secret of success with this method The hyoscine is dissolved in the methylpentynol so that no preoperative injection of atropine is necessary I still find this a very safe and satisfactory premedication for children.

Worthing F R GUSTERSON

SIR,—Dr Hodges' article prompts a few reflections from me As an early worker on the effects of hospital on young children I noted that "the operation for the removal of tonsils seems to be very traumatic, out of all proportion to its severity"[1] It was therefore very reassuring to note how, with modern methods, the trauma of the anæsthesia and the surgery could be reduced to a minimum

I was the more interested however in Dr Hodges' other finding—namely, that "factors other than anæsthesia may be more often responsible for psychic trauma", and he specifically mentions homesickness This would correspond to the psychiatrists' "emotional insecurity" (or overdependence) a feeling which, as explained in my monograph, is the key to the whole problem of hospitalisation One does not so much ask for special methods in hospital, I take it for granted that every effort is made to minimise the unpleasantness of the procedures there But one must always be prepared to find a few children for whom *the hospitalisation itself* is the distressing experience These are the potential cases of neurosis and may need added or special attention The majority of children, with normal sympathetic handling, "digest" and overcome the experience not so these few who fail on account of some inner problem making them the more vulnerable

Leeds H EDELSTON

CONTROL OF ANTICOAGULANT THERAPY

SIR,—Dr Matthews and Dr Walker (Dec 26), referring to the one-stage prothrombin-time, state "It is familiar to clinical pathologists and hospital doctors in general who, despite its theoretical and practical shortcomings, have confidence in the method and find it tolerably safe" Such a statement impugns not merely the reliability of the original test but also that of other procedures, especially the thromboplastin generation test, since the last step in the latter method is essentially a one-stage prothrombin-time

What are the theoretical shortcomings?

The one most commonly cited is that a prolonged prothrombin-time is generally not due to a decrease of prothrombin. When the test was developed, such factors as thromboplastin and prothrombin were recognised primarily as activities, and it was found by both the one- and two-stage methods that the level of prothrombin in the blood markedly dropped in vitamin-K deficiency and after the administration of dicoumarin With the observation[2] that the delayed prothrombin-time of stored oxalated human plasma could be completely corrected by the addition of fresh plasma depleted of prothrombin by adsorption with $Al(OH)_3$ or plasma from an animal given dicoumarin, it became evident that the test was also sensitive to a new clotting factor hitherto unrecognised It is now established that the test is not only sensitive to this factor (labile or V) but also to stable factor (VII) and to the less well-defined Stuart-Prower factor By adding to the patient's plasma a minute amount of labile factor in the form of deprothrombinised rabbit plasma, the prolonged prothrombin-time in congenital labile-factor deficiency is corrected to the normal of 12 seconds Likewise, the prothrombin-time is corrected to 12 seconds by the addition of normal aged serum in stable and in Stuart-Prower deficiency

Only in true hypoprothrombinæmia is there no correction effected by either adsorbed rabbit plasma or aged serum Thus, by simple modifications of the one-stage method, it can be made specific for any of the known factors in the prothrombin complex What is called a shortcoming is actually a pillar of strength The newly alleged shortcoming—namely, that it is not sensitive to the contact factor—would, no doubt, be serious if we had glass-lined blood-vessels

Interestingly, Matthew and Walker found a good correlation between the thrombotest and the Quick test while the "correla-

NATURAL HISTORY OF CAVERNOUS HÆMANGIOMATA

SIR,—We are discussing a very little understood condition, which in some ways might be classed with congenital deformities, and in others with new growths May I suggest a name for it which I have used for many years—“ the spreading angioma of infancy ” ? Nævus is a meaningless term, including stains and moles, “ strawberry ” as an adjective applies only to minor degrees, and there is nothing in them resembling caverns But they do belong to the vast and varied group of angiomata, they do grow, and this growth does occur in infancy

I wrote about one stage in the natural history of one type of these angiomata, the small but growing spot on the face which appears at or soon after birth They are often described by the mothers, who alone at this stage worry about them, as having started like a gnat-bite or a little scratch They are seen by general practitioners, doctors in clinics, pædiatricians, and obstetricians, but I have never known them at this stage to be referred to dermatologists or plastic surgeons This correspondence has made it clear what would happen if they were What they are apt to grow into is shown by the accompanying photographs, and the question I raised was whether this horrible development could be stopped

It must be clearly understood that it is not treatment at the stage illustrated which I am discussing, but treatment to avoid its occurrence

On the comparatively rare occasions on which I find these growing red spots I have been treating them by subcutaneous injections of saturated salt (sodium chloride) solution, which is non-toxic but extremely caustic, if injected into the skin it will cause a slough I get the impression that the violent cellular reaction produced in the deep tissues by this will begin the process of regression, at any rate none treated in this way has run wild as they so often do if left alone Supposing one were to get a hundred of these “ surgical emergencies ”—the growing red spots on the face—treat them with these injections, and find that there were no disfigurements of the kind shown, one would have some interesting though inconclusive information It would be inconclusive because it would be impossible to prove what would have happened had nothing been done, but then so much medical information is of this type

I have also been pleased with the results of injecting comparatively large quantities, up to 5 ml, into that type of angioma which closely mimics a rapidly growing sarcoma of the face, a deep elastic swelling with a faint blue tinge, under skin which at first is intact This type again is not referred to dermatologists or plastic surgeons, it sets difficult problems of diagnosis and treatment to the general surgeon

As to other methods of treatment, I dislike X rays, though they are undoubtedly effective during the period of rapid growth Carbon-dioxide snow is obviously completely futile on any but the very superficial types which are best left alone A primary excision is often the best as well as the most obvious treatment, it saves the mother years of embarrassment, and in

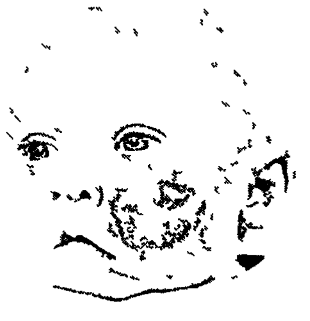

Fig 1

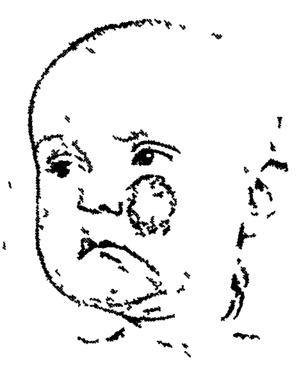

Fig 2

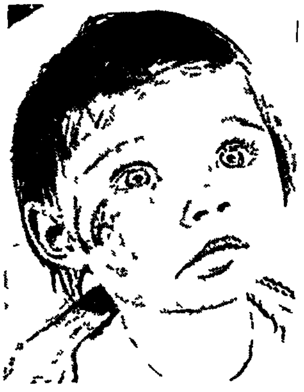

Fig 3

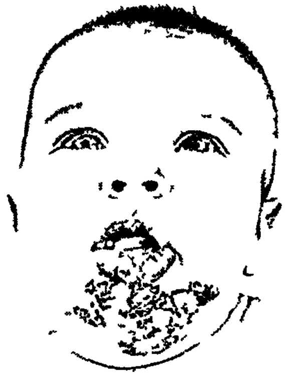

Fig 4

Fig 1—Angioma at stage of full growth, and beginning regression Started as small spot, will end as mass of redundant fibrous tissue

Fig 3—Similar case to figs 1 and 2, showing a more advanced stage of regression, with a baggy scar of the cheek

Fig 2—Similar case to fig 1

Fig 4—An angioma at the stage of rapid growth, showing many points at the “ gnat-bite ” stage It is obvious that bad scarring will result, and excision of the redundant tissues of the lip be necessary

any case often has to be done on the sagging mass of fibrous tissue left when regression is complete

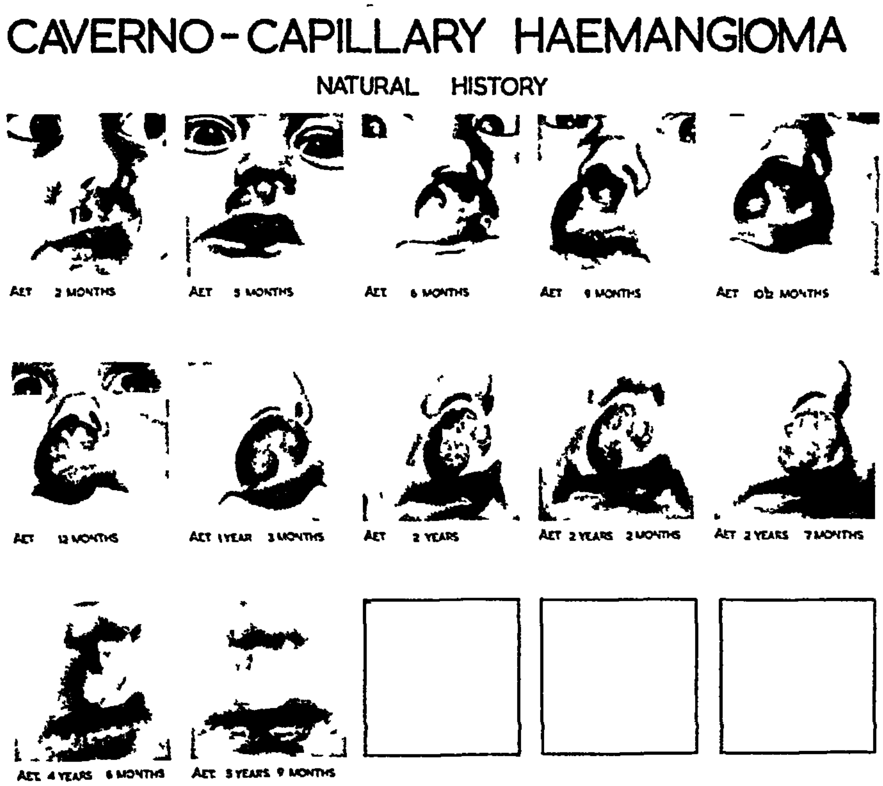
The substances used for sclerosing veins are unsuitable, being too toxic in the tissues The diathermy needle, insulated except for its point, is useful, but I have been afraid of injuring a nerve with it

But I realise that a concerted investigation of the kind I have suggested is impossible in the present fragmented state of my profession

London, W 1 DENIS BROWNE

SIR,—I have been very interested in the extensive correspondence on this subject, which was also debated at some length at a meeting of the Dermatological Section of the Royal Society of Medicine held at The London Hospital on June 18, 1959

My experiences conform closely to those of Dr Simpson (Dec 12) and I also follow Mr Murley's plan (Jan 9) of showing photographs to the parents



Some of your readers may be interested to see a series I collected in the past six years—not yet complete but very valuable for indicating to an anxious mother that Nature is on the side of recovery The large hæmangioma has disappeared at 5 years 9 months, leaving a residual soft fleshy excess of tissue which it is anticipated will disappear within the next few years The three blank spaces are for later photographs

Acknowledgment is due to the photographic department of The London Hospital

London, W 1 BRIAN RUSSELL

SIR,—In view of Dr Simpson's series and other meticulously followed-up and carefully analysed series illustrating the natural history of cavernous hæmangiomata, it astonishes me to find that anyone can strongly disagree, as Dr Millington (Jan 16) does, with these findings, which have been amply confirmed by the vast majority of dermatologists and plastic surgeons, when his sole criterion of satisfaction regarding his series of 1000 irradiated children is that "in a confined community such as this one would expect to be made aware of any untoward sequelæ of treatment"

Quite apart from unhappy sequelæ of irradiation, which Mr McLaughlin (Jan 16) so rightly deplores, Dr Millington's statement about "doubtful hopes of natural resolution" is in no way supported by the facts

Princess Margaret Hospital,
Swindon
K D CROW

SIR,—Dr Simpson's article on strawberry nævi and the subsequent correspondence have interested me greatly I have studied 152 consecutive children with 191 strawberry nævi, first seen between *1950* and *1953* Particular care was taken to make the follow-up as complete as possible, and the 9 children who were untraced are all known to have moved away from the district It is unlikely that they would have done this simply to seek surgical aid The results, which are being prepared for publication, are in complete agreement with Dr Simpson's and lend strong support to the view that conservative treatment is the best policy

HYDROFLUMETHIAZIDE

SIR,—With great interest I read the article[1] by Dr Edmonds and Professor Wilson A brief remark on p 308 deserves attention because it may contribute to removing the confusion which seems to prevail regarding the conception of the kaliuretic effect of the various derivatives of chlorothiazide and its theoretical background It reads "Hydroflumethiazide also possesses the sulphonamide group, and probably its lack of effect on bicarbonate excretion results from the much smaller quantity used"

Hydroflumethiazide and hydrochlorothiazide have a chloruretic effect which is about 15 times greater than that of chlorothiazide, as a consequence when using them the quantity of sulphonamide supplied is about 15 times smaller than when using chlorothiazide, to obtain a certain chloruretic effect Consequently the excretion of bicarbonate and therefore the kaliuresis are smaller However, it is doubtful whether these differences in "the primary kaliuretic effect" are of any therapeutic importance Experience shows that a potassium supplement is often necessary in prolonged treatment with all existing preparations of this group of diuretics, and it is very probable that the potassium loss is more closely connected with their chloruretic effect, as is the natriuresis, whereas the kaliuresis which is connected with the inhibitory effect on carbonic anhydrase is relatively small in comparison (although it is of course the smaller the less sulphonamide they contain in proportion to their chloruretic effect)

Of far greater therapeutic importance is undoubtedly "the secondary kaliuresis", which in certain patients may arise after administration of all potent diuretics with natriuretic effect, and which is a consequence of the increased secretion of aldosterone initiated by the organism as a " defence " against the increased natriuresis (as well as against too rigorous restrictions of salt in the diet) Recognition of this condition, and its treatment, are only in the embryo stage, but the introduction of spirolactone opens a wide field

---

[1] *Lancet*, 1959, ii, 303

A great deal of unnecessary discussion as to whether one diuretic should be preferred to another, especially with reference to the kaliuretic effect, might, however, be avoided if we (1) keep this quantitative situation of the sulphonamide group in mind, and (2) in each individual case try to establish whether the kaliuresis is primary or secondary

Hillerød, Denmark TORBEN ANDERSEN

FRUCTOSE TREATMENT OF PHENYLKETONURIA

SIR,—Some of our patients suffering from phenylketonuric oligophrenia have not been able to keep to their low-phenylalanine diets for various reasons Geisler and Stroder[1] reported that they were able to increase the phenylalanine tolerance and decrease the phenylketonuria of such patients by giving fructose intravenously or orally In order to see if fructose feeding (6 g per kg) would help our patients we tested two known phenylketonurics who have been receiving a normal diet at home

CASE 1 —A boy (H S C 208562) aged 8 years was first seen at the age of 2$^1/_2$ years suffering from frequent fits, deafness, and mental backwardness His general I Q was 20 and his plasma contained 30 mg per 100 ml phenylalanine and his urine contained phenylpyruvic acid Although treatment with a low-phenylalanine diet was started and his general I Q rose to 30, he failed to keep to the diet and has received a normal diet for the past four years (general I Q now 13)

CASE 2 —A girl (H S C 265841) aged 5 years was first seen at the age of 2 years because of frequent fits and mental retardation Her general I Q was 20, plasma-phenylalanine 30 mg per 100 ml , and her urine contained phenylpyruvic acid After eighteen months' treatment with a low-phenylalanine diet the general I Q rose to 30 and then remained stationary when the diet was not being adhered to For the past eight months a normal diet has been taken and the general I Q has fallen to 20 again

Each patient was fed on (1) a normal diet, (2) the same normal diet except that fructose 6 g per kg daily was substituted for all the sucrose or glucose normally taken, and (3) a normal diet again The fructose supplied all the sugar that was needed in the diet Plasma levels of phenylalanine were estimated by the comparison of paper chromatograms of known standards and desalted plasma Urine phenylpyruvic-acid levels were estimated by the method of The, Fleury, and Vink[2] The results are shown in the accompanying table

EFFECT OF FRUCTOSE DIET ON PLASMA-PHENYLALANINE AND URINE PHENYLPYRUVIC-ACID LEVELS

Case	Diet	Plasma-phenylalanine (mg per 100 ml)		Urine phenylpyruvic acid
1	Normal diet for the past 4 years, tested for 4 days	30		100–400 mg per 100 ml
	Fructose substitution (120 g per day) for 14 days	30		100–400 mg per 100 ml
2	Normal diet for past 8 months, tested for 4 days	30		70–200 mg per 24 hr
	Fructose substitution (120 g per day) for 8 days	50		50–220 mg per 24 hr
	Normal diet for 21 days	—		50–500 mg per 24 hr
	Fructose diet for 19 days	First day	50	Ferric-chloride test *strongly positive* daily
		Last day	50	

Bearing in mind the fluctuations in daily urine phenylpyruvic-acid excretion, it is seen that fructose feeding was not associated with any marked changes Plasma-phenylalanine levels also were not affected favourably Close observation in the ward showed that no changes in behaviour in either patient were associated with fructose feeding (Mr Stephen Coates)

Fructose feeding does not appear to have been of use in the treatment of these two patients suffering from phenylpyruvic oligophrenia

We should like to thank Mrs M B Hummerston, of the dietetic department, Sister E M Baldwin, of the metabolic ward, and Mr Stephen Coates, senior clinical psychologist, for their invaluable help in this investigation

A A MONCRIEFF
R H WILKINSON

REMOVING A SAFETY-PIN FROM THE BRONCHIAL TREE

SIR,—Would I be wrong in suggesting that Chevalier Jackson demonstrated Mr Donald Barlow's device (Jan 23) for removing an open safety-pin from the bronchial tree some 30 years ago?

The story was told in America that when Chevalier Jackson was tossing open safety-pins into an anæsthetised dog's trachea, a mild little man at the back of the room asked if he could have a go He mastered the technique, caught the night train, and removed the open safety-pin from the trachea of his infant patient

London, W 1 W HARGRAVE-WILSON

KEROSENE (PARAFFIN) POISONING

SIR,—Ingestion of kerosene (paraffin oil) is a common cause of accidental poisoning, particularly in children Recent animal studies by the Medical Research Division of Esso Research and Engineering Company, Linden, New Jersey,[3] have shown that kerosene poisoning is principally due to aspiration of the material into the lungs, where the kerosene produces a chemical pneumonitis The volume of kerosene required to produce a pneumonitis is very low thus, kerosene by aspiration into the lungs is highly dangerous By contrast, large amounts of kerosene can be ingested without pulmonary injury or ill effect

The accompanying table shows the oral toxicity of common liquid chemicals

ORAL TOXICITY OF COMMON LIQUID CHEMICALS

Chemical	L D $_{50}$ (mg per kg)	Toxicity class
Acetic acid (rat)	3310	Slightly toxic
Lactic acid (rat)	3730	Slightly toxic
Isopropyl alcohol (rubbing alcohol) (rat)	5840	Practically non toxic
Acetone (rat)	9750	Practically non toxic
Ethyl alcohol (rat)	13,660	Practically non toxic
Glycerine (rabbit)	27,000	Relatively harmless
Kerosene (rabbit)	28,350	Relatively harmless

If oral toxicity is low (high L D $_{50}$) the probability of systemic intoxication is low and removal of kerosene from the stomach is unnecessary

Clinical kerosene poisoning is probably due to aspiration of a relatively small volume of kerosene during or shortly after swallowing rather than to blood-borne kerosene absorbed from the gastrointestinal tract Since the oral toxicity of kerosene is low, the treatment should not include the induction of vomiting or other clinical procedures such as passage of a stomach tube for gastric lavage which may induce vomiting and thus aspiration (The present teaching in the first-aid manuals of the various societies is " Make the casualty vomit. Give copious draughts of water ") Since anti-emetics are central-nervous-system depressants, they are contraindicated because sedation and stupor are frequently found in kerosene poisoning Positive measures recommended are (1) oxygen if necessary, (2) antibiotics prophylactically, for the prevention of secondary bacterial pneumonia, (3) if the patient is conscious, ingestion of a vegetable oil or ice-cream to dilute the kerosene, diminish the rate of absorption into the blood, and soothe the inflamed mucous membranes of the gastrointestinal tract

THE PREP SCHOOL

SIR,—I was most interested to read the admirable review of the I A.P S report *Foundations* in your issue of Jan 2 In it you refer to the difficulty of finding suitable masters, and I thought you might be interested to know the steps that our Association takes to train those who teach in its schools

A joint committee of I A P S and the Oxford Institute of Education runs an eighteen-month training course on a correspondence basis with four short residential periods This is for young men and women who have recently taken up teaching In 1958 and in 1959 we put on a week's residential course at Oxford for men leaving the Services and intending to teach in our schools These courses had the approval of the Resettlement Board and were so successful that we hope to run another this year

Residential refresher courses are held for a week every April in Oxford for headmasters and their staffs, to ensure that the latest developments and methods in education are brought to their notice

LEISHMANIASIS ACQUIRED BY CONTAGION

SIR,—Professor Symmers is to be congratulated on his paper of Jan 16 which has made history, and is moreover most intriguingly and fascinatingly written It certainly gives rise to new appraisals and causes students of this subject most furiously to think

The outstanding facts are that it is possible for a man suffering from *Leishmania donovani* infection to pass it on by sexual intercourse to his wife, thus producing a local lesion in the vagina, to all extent and purposes resembling an oriental sore (attributable to *Leishmania tropica*) At first sight this course of events suggests that current beliefs need revising However, there may well be another explanation in the true ætiology in the analogy of Kenya kala-azar, where cultures of *L donovani* isolated from the gerbille, *Tatera vicina*, in the leptomonas stage, when inoculated subcutaneously into volunteers, gave rise to a local lesion, known as a leishmanioma [1] This is probably analogous to the primary lesion of epidemic kala-azar and which was first described by Clinton Manson-Bahr [2] in North Kenya It is from this leishmanioma on the tibiæ that the organisms spread throughout the body to subsequently produce the classical picture of visceral leishmaniasis (or kala-azar)

But more disturbing than this, from the viewpoint of the student of tropical medicine, is the recital of what may be called " a tragedy of errors " It is a sad commentary on the efficacy of the ancillary services of present-day medicine From the viewpoint of the consultant in tropical diseases I would venture to suggest that these avoidable mistakes arise primarily from the neglect of the fundamental principles of clinical medicine—the taking of a case-history How often one observes that the obvious diagnosis has been missed by neglect to do so, to find out, for instance, whether the patient has recently come from the tropics, subtropics, or other foci of endemic disease It is perfectly correct to state that the incidence of tropical infections has been much reduced, but it does not mean that they have been entirely swept away

PREVENTION AND TREATMENT OF BEDSORES BY SILICONE CREAM

SIR,—Much work has been done with silicone creams and emulsions in the prevention of bedsores Controlled trials showed that emulsion or cream must contain 20% silicone to be effective [1] Products with less than 20% silicone were ineffective, and additional silicone over 20% did not increase the efficiency of the cream or emulsion

Silicone emulsions in the prevention and treatment of bedsores have now been used by the district nurses in Flintshire since 1954 with very good results They have the following advantages (*a*) they are more effective than soap, water and spirit, and (*b*) they show a considerable saving of nursing time in the treatment of pressure-points Recently two new silicone preparations have been given a trial in this county and have proved more effective than plain silicone emulsion

One cream (bedsore cream I) contained 20% silicone fluid MS200, 0 05% phenylmercuric dinaphthylmethane disulphonate ('Penotrane'), and 0 5% dienœstrol The other (bedsore cream II) contained the same amounts of silicone and penotrane but omitted the dienœstrol Both creams were of pH 4 2, approximating to that of normal skin [2]

District nurses who had considerable experience of silicone emulsions tried each of these creams in a number of patients The record cards kept by the nurses show that both creams were more effective than plain silicone emulsions in the prevention and treatment of bedsores Ten patients were treated with cream II (penotrane/silicone cream) and eight with cream I Cream I seems more effective but it is only fair to emphasise that the number of cases treated so far is small

The advantages of the new cream can be summarised as follows

(1) They produce more rapid healing of damaged skin over pressure-points than do plain silicone emulsions
(2) They appear to be more effective in penetrating the skin, and more efficient in protecting the skin of incontinent patients
(3) They are easy to apply and repeated applications do not tend to " cake " on the skin

As many hospitals and local health authorities are now using silicone emulsions, these small trials with the new silicone creams might be of interest

The two creams used in the trial were kindly supplied by Messrs Ward, Blenkinsop, from whom the plain penotrane/silicone cream is now commercially available The cream containing penotrane and dienœstrol is only available for clinical trials at present

DENTAL CARIES

SIR,—I was very pleased to see in your leading article of Jan. 16 that the importance of Stack's protein is recognised, as well as its significance in relation to the observations that caries is primarily a deficiency disease. (The term "Stack's protein" is preferable to "soluble protein" as it is only soluble under pathological conditions.) Indeed, there is now sufficient evidence available for one to be still more precise about the mechanism of the carious process.

You state that "about equal quantities of each type of protein are present in the interprismatic spaces, and the soluble protein is assumed to be the first part of the tooth substance to disappear." It is not quite clear what is meant by "interprismatic spaces." The electron-microscope photograph (fig. 1) shows the distribution of the two proteins in dental enamel before calcification. The denser keratin is in the prism walls and Stack's protein in both prism core and interprismatic regions.[1] When calcification occurs, apatite crystallites are deposited in, and protected by, both proteins.[2] Professor Darling and his coworkers have shown that the first stage of the carious process is the degradation and/or solution of Stack's protein.[3,4] This presumably exposes its apatite crystallites to further attack, and fig. 2 shows the state of affairs in chalky enamel, which is the second stage of the carious process. Here the prism walls remain normal, but without Stack's protein the crystallites which had been protected by it have mostly gone.

It seems probable that the stability of the protein is determined at the time of its polymerisation,[5] and that vitamins or trace elements act as catalysts in the process. There is abundant evidence from all parts of the world to show that the incidence of caries is related to diet. Lady Mellanby[6] showed that vitamin D, which reduces the incidence of caries, affects the matrix, and the paper quoted on vitamin B_6[7] shows that other vitamins have to be considered too. Clinically it is known that fluorine causes a very substantial decrease in caries incidence, and experimentally Darling and Brooks[8] have shown that fluorine also modifies matrix production. At present there is not sufficient evidence to show whether caries is primarily a vitamin deficiency, a fluorine deficiency, or a combination of the two, but there is nothing against the belief that fluorine is the more important.

The other main factor which is a practical consideration in the prevention of caries is the prevention of solvents from reaching the vulnerable protein. In perfectly formed teeth this is achieved by means of the surface zone. But it is of interest to remember that there are many instances of the surface zone being worn away in "uncivilised" communities without caries resulting. Acids and oxidising agents are undoubtedly partly responsible for caries; but when one examines critically the evidence for bacteria and refined sugar, traditionally regarded as causative factors, their claim seems to be curiously elusive. The bacteria appear in large numbers only after the carious process has been initiated. They are very probably more resistant to degradation than Stack's protein, so that it is worth considering whether components of toothpastes aimed at bacterial degradation are not even more likely to affect the Stack's protein, if this is exposed by abrasion or attrition.

Nuffield Orthopædic Centre,
Oxford

TREATMENT OF CUSHING'S SYNDROME

SIR,—Dr. Montgomery and his associates[1] have commented on this very important problem by describing the occurrence of large pituitary tumours (one malignant) after adrenalectomy in 2 cases of their own and by collecting similar cases from the literature. They conclude that "... possibly in the future we shall have to consider hypophysectomy as an alternative to adrenalectomy more often than we do at present."

On the basis of 36 years' experience with the many aspects of Cushing's syndrome (my first case observed in 1923 was included by Cushing in his original description of the disease entity named after him[2]), I should like to offer yet another alternative—hands (that is, surgical hands) off the majority of patients who fall under this, of late, very loose heading. Of course I do not wish to imply that patients who are suspected of harbouring a carcinoma or even an adenoma of the adrenal cortex should be kept from surgery. I am referring to the vast majority of patients who have no evidence (e.g., in air-insufflation studies) of a gross adrenocortical lesion, unilateral or bilateral, or the full-blown clinical symptomatology, or at least gross hypertension which by itself may justify operation. In such patients the presenting symptom is commonly the characteristically distributed obesity with moon face and purple striæ associated with mild to moderate hypertension and/or diabetic tendencies (often very unstable) and with little or no abnormality of steroid excretion. In these formes frustes an attempt may in my opinion be made with a rigid dietary regi-

---

2. Cushing, H. *Bull. Johns Hopk. Hosp.* 1932, 50, 137.

men, supported by appetite depressors and possibly by the judicious use of dehydration. As I have often emphasised,[3-7] very satisfactory results can thus be obtained, comparable to the remissions after surgery Of course, relapses do occur, but so they do after surgery, moreover, this conservative therapy can be repeated at will, without fear of untoward side-reactions If the patient fails to respond, an attempt may and indeed should be made with X-irradiation to the pituitary region before surgery is considered

I agree that this treatment is neither infallible nor ideal Nevertheless, I was led once more to stress the conservative method in the treatment of Cushing's syndrome after reading Dr Montgomery's paper, which illustrates not only the well-known risks of adrenalectomy—namely the Scylla of adrenal insufficiency and the Charybdis of a recurrence—but adds to this list the possible development of pituitary tumours which may necessitate yet another and certainly not harmless operation

Jerusalem HERMANN ZONDEK

ELECTRIC SHAVERS AND EYE AFFECTIONS

SIR,—It is now widely conceded that various inflammatory conditions of the eye, and in particular, the conjunctiva, may well be initiated by microscopic fragments of dandruff which lodge in the eye during combing or brushing of the hair I would draw attention to another and more potentially dangerous source of similar irritation and/or self-infection—the electric shaver At least one well-known manufacturer advises users to remove the shaving "head" after shaving and "blow across it" to remove the dust, which is composed, in persons with facial seborrhœa or abnormally dry skin, of powdered skin (or "scurf") and very small fragments of hair

Many persons almost certainly blow right *into* the shaving head in order to more effectually dislodge the dust, thereby driving some of the dust into eyes, nose, and mouth

When the possible cumulative effect is considered (this is done at least 365 times a year!) the effect on the lungs might also be considered

Cheltenham R. ST C ISON

OVERDOSAGE OF PHENELZINE SULPHATE

SIR,—The manufacturers of 'Nardil' (phenelzine sulphate) state that this recently introduced drug provides "safe and effective treatment for the outpatient management of milder depressive illnesses" The following emergency seems worth reporting

A married man, aged 32, was admitted to hospital on Nov 28, 1959, after taking an overdose of 16 tablets (400 mg) of phenelzine sulphate The psychiatric history indicated that during the preceding 12 months he had been increasingly anxious over the payment of hire-purchase commitments Early in October, 1959, he was angry and disappointed on receiving what he considered was insufficient payment for overtime work. He became more anxious, and finally depressed over arrears in his hire-purchase payments He then had a hysterical fugue and wandered to a village some 20 miles away On returning home he was subsequently referred to two psychiatric departments in the area but opted out of treatment at each establishment. On Nov 25, 1959, he became severely depressed and was preoccupied with the idea that he had let his wife and child down badly He was given a supply of phenelzine sulphate tablets by his general practitioner and on the night of Nov 26 took 16 tablets at once Almost immediately he became gay and elated ("I felt champion") but after some hours became acutely anxious about the possible consequences of his act. His wife took him to hospital where his stomach was washed out Following this procedure he slept deeply for 24 hours By Nov 30 he was reasonably well

This case suggests that the outpatient use of thymoleptic drugs may in fact not be without danger It also seems to confirm that phenelzine is indeed a thymoleptic

It would be interesting to know whether any of your readers have encountered similar cases and what, in general, is the contemporary trend of opinion concerning the outpatient control of medication with thymoleptic drugs

ANTIBODIES AGAINST ADENOVIRUSES

SIR,—Data about the incidence and type distribution of adenoviruses in Hungary[1 2] are slight A serological survey, using the methods of complement fixation (C F)[3] and virus neutralisation, was therefore made on various human sera

As an antigen a mixture of the first 7 types of adenoviruses obtained in tissue cultures was used Neutralisation tests were made in Detroit-6 cell cultures, using adenoviruses of types 1 to 7 separately A total of 1174 human sera were examined by C F and 148 by neutralisation test Results of C.F are shown in table I The groups of serum samples were as follows

TABLE I—RESULTS OF C F REACTION

Group	No of sera tested	% of C.F positive	Average titre
1	85	41 (*48 2%*)	1 8 8
2	61	15 (*24 5%*)	1 11 6
3	163	24 (*14 7%*)	1 4 8
4	117	16 (*13 6%*)	1 10 7
5	632	268 (*42 4%*)	1 5 6
6	116	56 (*48 2%*)	1 7 3
Total	1174	420 (*35 7%*)	1 6 5

Group 1—Sera of children, mostly under 5 years, convalescent after an attack of poliomyelitis

Group 2—Sera of persons of 10 to 20 years, in hospital with pulmonary tuberculosis

Group 3—Students of 18 to 20 years of age called for medical examination before admission to the University Medical School

Group 4—Random serum samples from apparently healthy persons over 20 years of age

Group 5—Sera from patients under medical cure with a diagnosis other than disease of the upper respiratory tract

Group 6—Patients with acute respiratory disease

C F titre values varied between 1 4 and 1 64 for the different groups, and the maximum incidence was within the range 1 4 to 1 8 This observation agrees with the results of others[4] The proportion of positive sera decreased remarkably in those over 40–50

For neutralisation tests some of the sera with positive C.F reactions were selected from all 6 groups The highest incidence

TABLE II—DISTRIBUTION OF NEUTRALISING ANTIBODIES IN 148 SERA AGAINST TYPE 1 TO 7 ADENOVIRUSES

Antibody against	Sera containing antibody
Type 1	93 (*62 8%*)
Type 2	81 (*54 7%*)
Type 3	52 (*35 1%*)
Type 4	59 (*39 8%*)
Type 5	65 (*43 9%*)
Type 6	65 (*43 9%*)
Type 7	73 (*49 3%*)

of neutralising antibodies was observed against types 1, 2, and 7 of adenoviruses, while those against types 3 and 4 were found only very seldom (table II) As to the simultaneous occurrence of different antibodies against the first 7 types of adenoviruses in the sera tested, the following figures were obtained

Against 1 and 2 types 19 5% and 18 2% incidence of antibodies was observed respectively Against 3 and 5 types 16% and 17% of sera contained simultaneous antibodies respectively The simultaneous occurrence of antibodies against 6 types was 9% and against all 7 types tested 2 7%

The proportion of positives was highest in the age-group 31–40 Thus persons in this group apparently had the highest simultaneous incidence of antibodies against the 7 different groups of adenoviruses tested

A more detailed presentation of our results will be published elsewhere

M TÓTH

MATERIAL FOR CUBICLE CURTAINS AND WARD SCREENS

SIR,—The modern trend of thought for patients' privacy has focused attention on materials suitable for curtains and screens Whilst bacteriological reasons would appear to condemn these as dangerous, it is clearly desirable for workers to endeavour to find a suitable material

The following problems had to be faced in evaluating the claims of fabrics

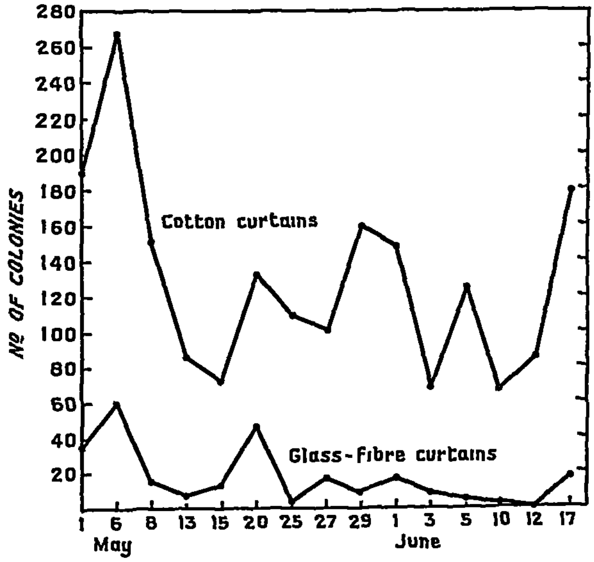
(1) Fluff any material increasing the amount of fluff with its attendant carriage of bacteria is not acceptable
(2) Resistance to the collection and release of bacteria in clouds when drawn or moved
(3) Inflammability
(4) Ease of hanging and washing
(5) The electrostatic risk
(6) Economy

Plastic materials proved a problem from the electrostatic angle, and were difficult to change and clean. They became stained, brittle, and cracked

Preliminary tests with woven-glass-fibre materials (' Vetrona Fabrics ') were very satisfactory and a trial was made in a test ward where 3 beds were curtained with cotton curtains and 3, immediately adjacent, curtained with glass-fibre curtains

The glass-fibre curtains showed the following advantages

(1) Absence of fluff
(2) Resistance to the collection of bacteria
(3) Non-inflammable
(4) Hung with nylon runners on a plastic rod, they were easily withdrawn and rinsed in ' Hytox ', 15 fl oz to a 15-gallon bath of water for 15 minutes, drained and rehung immediately
(5) Non-electrostatic
(6) Very economical, priced at approximately twice the cost of the usual cotton materials, only one set is required owing to saving in laundering, and resistance to wear appears much greater than with cotton



Number of colonies from 3 cotton curtains and 3 glass-fibre curtains

Bacteriology

The accompanying figure shows the counts obtained in the test As sweep plates were useless owing to the nature of the material, tests were made by making a hole in the bottom of an old petri-dish box The agar plate was exposed in the inverted lid of the box, the curtain to be tested stretched over the lid, the box replaced into the inverted lid, thus stretching the material taut, a 5 g weight dropped through the hole in the bottom, and 15 seconds allowed to elapse for bacteria to settle After 48 hours' incubation all colonies were counted on the 3 plates taken from the 3 cubicles (i e , 1 from each) These were taken between 10 30 and 11 A M

The upper line indicates readings from the 3 cotton curtains and the lower for the 3 glass-fibre curtains On June 12 only 2 colonies were recovered from the 3 glass curtains after 6 weeks' use in an overcrowded gynæcological ward admitting many septic abortions The curtains were not laundered, cleaned, or treated in any way during this test Laundering of these curtains can clearly be left to intervals of several months if further trials confirm these results, and the saving of labour is therefore very great

We are grateful to Messrs Vetrona Fabrics Ltd , Sunnyside Mills, Bolton, Lancs, who made available to us the curtains for this experiment

CHROMATOGRAPHIC ESTIMATION OF CORTICOSTEROIDS BY ^{14}C-LABELLED TETRASOLIUM SALT

SIR,—Often very small amounts of corticosteroids have to be determined in clinical and experimental work The generally used reactions (tetrasolium-blue colour reaction and the " soda-fluorescens " procedure) are often unsatisfactory because of their low sensitivity (0 3–0 5 µg per sq cm)

For the microdetermination of corticosteroids previously used methods were followed with isotope-labelled corticosteroids In this way ^{14}C or ^{3}H corticosteroids could be measured by dilution or acetylation in the presence of acetic anhydride containing ^{14}C or ^{3}H These methods raised technical difficulties, so we used ^{14}C-labelled tetrasolium salts (triphenyl-tetrasolium chloride and tetrasolium blue), which gave colour reactions with the corticosteroids We then performed determinations with pure steroids The tetrasolium-formazan produced could be separated easily from the superfluous tetrasolium chloride or tetrasolium blue on the basis of their dissolution relations (tetrasolium chloride and tetrasolium blue dissolve well in water, while the organic-soluble formazan does not)

For the detection a gas-flow GM-counter was used, by which we were able to measure 0 05 µg of corticosteroid According to our calculations, with a specific activity of 2 mC per g and these detection techniques, the determination of about 0 01 µg of corticosteroid is also possible Our present work is designed to determine the corticosteroids in biological fluids

RED-CELL DIAMETER IN INDONESIA

SIR,—Our investigations of red-cell diameter in our country show higher normal values of 7 39 μ (male 7 38 μ, female 7 40 μ)

The subjects for these measurements were 30 males and 10 females, all members of the staff of preclinical departments They showed no signs of anæmia and hæmoglobin level, red-cell *count*, *colour-index*, packed-cell volume, and standard deviation were within normal limits

The technique used was the microprojection method described by Price Jones, but a groundglass screen was used With this modification, magnification of 5000 times is still clear enough to distinguish the erythrocyte's outlines sharply 500 red cells were measured in each subject

Although we obtained higher values for mean corpuscular volume (80 3–116 7 cμ) which is not surprising, we also obtained lower values for mean corpuscular hæmoglobin (24 6–34 8 $\mu\mu$g) and mean corpuscular hæmoglobin concentration (28 5–37 6%) Clearly increase in diameter parallels increase in mean corpuscular volume but not necessarily mean corpuscular hæmoglobin or mean corpuscular hæmoglobin concentration. This suggests that Burker's rule, which states that the hæmoglobin content of the red cells is proportional to the surface area, is not valid for normal or for pathological cells

EMERGENCY RESUSCITATION IN RUPTURED ECTOPIC GESTATION

SIR,—I was interested in Dr Azie's letter of Dec 12 As these cases are always extremely urgent I consider that looking for a compatible donor is a waste of time

I think that a slight improvement on Dr Azie's technique, where the facilities are available, is as follows

When the patient is ready for operation an intravenous plasma or dextrose saline drip is started When this is working properly it is stopped, because, as Dr Azie says, it is only diluting the blood and washing red cells into the peritoneum

The abdomen is then opened and the bleeding stopped in the usual way A sterile transfusion bottle containing sodium citrate has in the meantime been attached to a sucker The sucker is turned on and when the bottle is full it is exchanged for the plasma or saline bottle and blood-transfusion is started Another transfusion bottle is then attached to the sucker In this way several pints of blood may be collected rapidly for subsequent transfusion when the patient has returned to the ward A bowl of sterile normal saline is kept handy in case the sucker becomes blocked

This method has the advantage that less blood is wasted and there is no guddling about with soup ladles, &c

HIGH PLASMA-IRON IN PORPHYRIA

SIR,—During the course of a survey of Africans with porphyria, we measured the plasma-iron levels in 23 consecutive patients, with the following results

In 15 cases, the plasma-iron was over 200 μg per 100 ml , the highest being 345 μg per 100 ml (The mean plasma-iron level for normal African subjects in Durban is about 100 μg per 100 ml)

2 of the remaining 8 patients had amœbic dysentery, and a 3rd had pulmonary tuberculosis, infections are known to lower plasma-iron values, and this may account for the relatively normal values found in these 3 patients

Large increases in plasma-iron have, to our knowledge, been reported only in patients with hæmochromatosis and transfusion siderosis,[1] in a proportion of African patients with nutritional siderosis,[2] in infectious hepatitis,[3] in some types of anæmia, and after iron administration

It would be of interest to know whether other workers have measured plasma-iron in cases with other types of porphyria If similar high levels have been found, it might throw light on possible relationships between porphyrin biosynthesis and iron metabolism

THE COST OF DRUG TREATMENT

SIR,—Dr Harman's report of his impressions derived from " economy committees " are entertaining and no doubt are not meant to be taken seriously As however his letter has prime place in your columns on Jan 23 and refers to a serious problem in the economy of the N H S , comment from one to whom its conclusions are antipathetic may be justified

His first generalisation that waste is inevitable is followed by a defeatist recommendation that it had better be accepted It will be generally admitted that any organisation which aims at efficiency takes steps to limit waste to the minimum, whether it be in the home, big business, or a Government department In attempting to control extravagant expenditure in drugs the administrator can do little more than issue recommendations unless he interferes unduly with the doctor-patient relationship, and the drug houses cannot be prevented from advertising On the other hand, the medical practitioner surely can by act and advice exert considerable influence The cooperation of doctors is the key to the problem, and we should not divest ourselves of the social responsibility though it may not be a matter of direct self-interest Savings on drug expenditure leave more money for hospital building, more doctors, and more pay for them

Whether a high drug bill should be a source of national pride is a matter of opinion Certainly those who doubt the contribution of much drug-taking to what is called the positive health of the nation would not agree to the proposition

In the last paragraph of Dr Harman's letter I do not know what is meant by " its own law of growth " Does it derive from Parkinson or Dr Pangloss ? Anyhow I do not think the profession should adopt an attitude of laissez-faire in its approach to the problem at issue

Selling, Faversham, Kent

MAX PAGE

SIR,—In their paper of Jan 2 Dr Miller and Dr Smith suggest that distributive costs may account for one-third of the total national drug bill

This is not unlikely It should be realised that the cost of most consumer goods increases by at least 50% between leaving farm or factory and their purchase by the consumer (discounting the distorting effects of subsidies, purchase-tax, and similar taxes) Often the increase is far greater

The cost of distributing drugs in the National Health Service would thus not appear to be excessive in comparison with the cost of distributing other consumer goods

West Middlesex Hospital,
Isleworth, Middlesex

J R SEALE

SIR,—Of the letters dealing with our paper, I think only that of Dr Springett calls for a reply P A S is marketed in many forms, and its basic cost varies by almost 300% Our figure was based on the price of P A S powders obtaining in July, 1959 Dr Springett is right in suggesting that the drug is cheaper in tablet form, and where both drugs are prescribed its combination with isoniazid effects a further economy

INCIDENCE OF ISCHÆMIC HEART-DISEASE AMONG INDIANS IN KENYA

SIR,—So much has been written about the relationship between fat intake and coronary disease that a statistical survey of the disease amongst the various Indian sections in Kenya might prove of value, since these groups vary so greatly in their animal fat consumption

The Asians, excluding the Goans, may be divided into five main groups

(1) Gujerati, vegetarians (non-Muslims)
(2) Gujerati, non-vegetarians (mainly Muslims)
(3) Punjabi, vegetarians (non-Muslims)
(4) Punjabi, Sikhs (non-Muslims) *(Females usually vegetarian and males non-vegetarian)*
(5) Punjabi, non-vegetarian (Muslims)

The fat consumption rises in this order from (1) to (5), being least in the Gujerati vegetarians and greatest in the Punjabi non-vegetarian Muslims

TABLE I—NUMBER OF MALE CASES IN EACH GROUP AT DIFFERENT AGES

—	30-39	40-49	50-59	Over 60	Total
Gujerati vegetarians	10	30	44	28	112
Gujerati non-vegetarians	2	17	16	10	45
Total Gujeratis	12	47	60	38	157
Punjabi vegetarians	4	11	18	8	41
Punjabi non-vegetarian Sikhs	1	9	12	10	32
Punjabi non-vegetarian Muslims	2	8	10	6	26
Total Punjabi non-vegetarians	3	17	22	16	58
Total Punjabis	7	28	40	24	99
Total Indians	19	75	100	62	256
Goans	1	14	14	14	43

The population figures have been calculated from the census for 1948,[1] according to which males over the age of 15 number 29,000 Indians and 3000 Goans The Asian population, it is estimated, increased by 2½% per annum since that year, but the proportion between the various groups has remained about the same [2] Muslims form 31% and non-Muslims 69% of the Indian population, Muslims thus comprising 9000 and non-Muslims 20,000 males over the age of 15 Hindu males at the same age number 15,000 and Sikhs 3000 Further assessments have been obtained by inquiry from electoral candidates who subdivide their electorates in order to estimate their supporters who come mainly from their own communities, in this way it has been calculated that Gujerati Hindus (vegetarians) outnumber Punjabi vegetarians by about 2 to 1, and that Gujerati Muslims (non-vegetarians) exceed Punjabi Muslims by the same proportion The relative figures of these groups for males over the age of 15 are Gujerati vegetarians 10,000, Punjabi vegetarians 5000, Gujerati Muslims 6000, and Punjabi Muslims 3000

TABLE II—STANDARD DAILY DIETS OF EACH GROUP

Item	Gujerati veg	Gujerati non-veg	Punjabi veg	Punjabi non-veg
Atta	10 oz	9 oz	14 oz	12 oz
Rice	3 oz	3 oz	1 oz	2 oz
Dhall	2 oz	2 oz	3 oz	2 oz
Vegetables	8 oz	6 oz	8 oz	6 oz
Sugar	3 oz	3 oz	3 oz	3 oz
Meat	Nil	4 oz	Nil	5 oz
Eggs	Nil	1	Nil	1
Milk	6 oz	6 oz	12 oz	12 oz
Ghee	2 oz	2 oz	3½ oz	3½ oz
Vegetable oil	1½ oz	1½ oz	Nil	Nil

Atta is coarsely ground wheat flour, plus 15% bran Dhall is the pigeon pea, *Cajanus indicus* Vegetable oils, which are prepared locally, include *simsim oil, which is made from millet, groundnut oil*, and cottonseed oil, none of which are hydrogenated

The figures for milk in the original table have been altered to conform with the average adult consumption at the present time

The male Indian population of Kenya over the age of 15 therefore includes the following main groups

Gujerati vegetarians (Hindus)	10,000
Gujerati non-vegetarians (Muslims)	6000
Total Gujeratis	16,000
Punjabi vegetarians (Hindus)	5000
Punjabi non-vegetarian Sikhs	3000
Punjabi non-vegetarian Muslims	3000
Total Punjabi non-vegetarians	6000
Total Punjabis	11,000
Total Indians in these groups	27,000

Our series consists of 320 consecutive cases of ischæmic heart-disease seen in Kenya during the past thirteen years, including 170 Gujeratis, 104 Punjabis, and 46 Goans All the diagnoses were confirmed clinically and electrocardiographically by one of us Necropsy in fatal cases was never possible, since Indians in Kenya never allow postmortem examinations on their relatives All were men with the exception of 21 women (18 Indians and 3 Goans)

A comparison between the 153 vegetarian and the 103 non-vegetarian males showed that hypertension was slightly more frequent (30%) amongst vegetarians than non-vegetarians (25%) and that diabetes had approximately the same incidence (13% and 15%) in the two groups The total Gujeratis and total Punjabis displayed almost the same proportions of each disease

The ages of the male patients in the various communities are given in table I, which reveals that the incidence of coronary disease is highest in the sixth decade

The standard daily diets of the main Indian groups [3] are listed in table II According to Adalja,[2] the average consumption of milk and ghee has fallen by about 30% since 1927, partly because more tea, and correspondingly less milk, is taken, and partly because these substances were thought to give protection against malaria and pneumonia before the advances of chemotherapy There has also been a tendency since the end of the late war for a few of the vegetarians to be less strict in their diet, particularly when they go out to meals with members of other communities

The incidence of ischæmic heart-disease in relation to Kenya population in the different groups, is depicted in table III

TABLE III—INCIDENCE OF ISCHÆMIC HEART-DISEASE IN MEN IN RELATION TO MALE POPULATION OVER THE AGE OF 15

—	No of cases	% of total Indian cases	Kenya population (approx)	Population % of total Indians
Gujerati vegetarians	112	44	10,000	37
Gujerati non-veg	45	17	6000	22
Total Gujeratis	157	61	16,000	59
Punjabi vegetarians	41	16	5000	19
Punjabi non-veg Sikhs	32	13	3000	11
Punjabi non-veg Muslims	26	10	3000	11
Total Punjabi non-veg	58	23	6000	22
Total Punjabis	99	39	11,000	41
Total Indians	256		27,000	

For the sake of accurate comparison females have been excluded because they form such a small proportion of the coronary cases and because the sexes of the Sikh community differ in their diet, females being predominantly vegetarian whereas males are usually non-vegetarian Since the Statistical Abstract [1] gives no separate figures for population between the ages of 15 and 60, the estimates in this table comprise males over the age of 15

The ratio between percentage incidence of ischæmic heart-disease and percentage of population is almost identical in the total Gujeratis and total Punjabis, the percentage coronary moribidity in each case being closely proportional to that of population, in spite of the fact that the Gujeratis are the lowest and the Punjabis the highest fat consumers These statistics suggest, therefore, as was hinted by Adalja,[4] in the case of Indians nya the ingestion of animal fats is not an important gical factor Another point of interest is that the nt of vegetable oils, such as simsim, groundnut, cottonseed oils, which are not hydrogenated, tends consumed in inverse ratio to that of animal fats us seems that the Gujerati vegetarians were not cted from coronary occlusion by a high intake of urated fatty acids

---

[1] Statistical Abstract, East African Statistical Department, Kenya Unit, 1958

[2] Adalja, K V Personal communication, 1959

[3] Harvey, D *East Afr med J* 1943, 20, 235

oking does not seem to be an important factor Sikhs, who never smoke, show approximately the incidence of ischæmic heart-disease in relation to population as the other Punjabis and total Gujeratis, ngst whom smoking is practised by most Indian over the age of 25

e consider that further research into the comparative ence of coronary occlusion amongst the various communities in Kenya, analysis of their diets, and ting of their populations might throw more light the ætiology of the disease

wish to express our gratitude to the Hon Dr K V Adalja s valuable assistance in classifying the various Indian groups providing particulars concerning their population and diet e also grateful to the doctors who referred their cases to us

B P ARYA

HOTELS OR HOSPITALS?

R,—I have read Mr Stallworthy's article of Jan 9 great interest Experience of the operation of con- cent annexes or halfway houses attached to geriatric supports his suggestion that the provision of these es for other medical units would be of value A ber of halfway houses have been established by the Edward's Hospital Fund for London and by the onal Corporation for the Care of Old People, and my rvations are based on the working of the home hed to the geriatric unit of the Whittington Hospital ng the past nine years

e adverse psychological effects of prolonged stay of tric patients in the hospital ward are well recognised t from apathy and personality deterioration many patients, ng incentive, become dependent on the services of the ing staff Whereas what is needed is encouragement for patient to become independent after the acute phase of his s has been treated Independence is often more easily eved in the halfway house than in the hospital ward One e most important functions of the halfway house is to ide facilities for further rehabilitation and thus shorten the th of stay in hospital The patient with hemiplegia, for ple, may have recovered sufficiently in hospital to be able alk, but because he cannot dress himself or manage stairs s still dependent on help from others He can learn to orm these activities in the halfway house where a marked rovement in morale and speed of recovery is often noticed onfidence and interest in living are renewed Hemiplegic ents whose recovery was satisfactory spent on the average eks in the geriatric unit and a further 5 weeks in the half- house before returning to an independent existence at e

nother important advantage of the recovery annexe or way house is that the patient's physical and mental capabili- can be more easily assessed there than in the hospital ward s the patient is not discharged home until it is reasonably ain that he or she is capable of managing at home As a lt premature readmission to hospital can be avoided ms[5] found that with the availability of the beds in Seapark, a recovery home attached to the Belfast Geriatric Unit, the readmission-rate in 1953 fell from its usual level of 12% to 8%

The possible dangers of loss of continuity of care mentioned by Mr Sanford (Jan 23) are not present in the case of the halfway house whose operation I have observed But continued regular visits by the hospital consultant and by the almoner are essential As far as possible the plan for the patient's further care is decided upon before he is transferred from hospital to the annexe The successful operation of halfway houses at present in existence, their undisputed value to geriatric units, and the substantial contribution they make to the recovery of many elderly patients indicate the need for similar homes attached to other medical units which are treating an ever-increasing proportion of patients in the older age-groups

London, N 19

A N EXTON-SMITH

FIBRINOLYTIC ACTIVITY OF BLOOD IN INTERMITTENT CLAUDICATION

SIR,—We were interested to read Dr Nestel's paper of Sept 19, in which he says that deficient fibrinolysis has been previously demonstrated only in acute episodes, as in coronary occlusion In this clinic, the fibrinolytic activity was measured in thromboangiitis obliterans, arteriosclerosis obliterans, and atherosclerosis

Fibrinolysis in the euglobulins was depressed in 6 out of 24 cases of arteriosclerosis obliterans and in 4 out of 21 cases of thromboangiitis obliterans In 100 patients with atherosclerosis there was a tendency to deficient fibrinolysis in the euglobulins and a statistically important prolongation of fibrinolysis time of total plasma activated with streptokinase No changes in plasminogen activity were found. A possible relation of these findings to the antifibrinolytic activity was considered

The results[1] were given to the XIX Congress of the Polish Internists Association in Poznan in September, 1957, and to the XX Congress in Gdansk last September The problem of fibrinolysis in atherosclerosis was also discussed by other Polish authors (E Szczeklik et al and H W Gajewski)

WINCENTY CZARNIECKI

ANABOLIC STEROIDS AND RADIATION DAMAGE

SIR,—Szold et al[2] and Fehér et al[3] demonstrated significantly higher survival-rates in nephrectomised uræmic animals treated with an anabolic agent, 19-nor-androstenolone phenylpropionate ('Durabolin') than in controls The uræmic state has many similarities to acute radiation sickness, and the idea was thus raised that acute radiation damage might be retarded or prevented by anabolic agents

Adult male rats were given a total-body dose of 1000r (180 kV, 6 mA, 2 5 Al filter, 50 cm focus-skin distance, the dose controlled with a Siemens-Universal dosimeter) The animals to be protected were given, at the onset daily, later on every second day, 0 5 mg of 19-norandrostenolone phenylpropionate, and the controls received the same amount of physiological saline

From the second day after irradiation the clinical appearance of the animals became very similar to that of rats with arenal uræmia, with the difference that the symptoms of the protected animals were significantly less The protected animals were fresher, responded better to external stimuli, were curious, and had a better appetite Before they died all became restless and dragged their hind limbs which were subject to convulsive spasms

---

dalja K V Kenya Faculty of the College of General Practitioners, London Oct 4, 1958

dams, G F *Lancet*, 1954, ii, 486

[1] *Polskie Archiwum Medycyny Wewnętrznej*, 1958 12, 1569

[2] Szold E, Szendrői, Z, Weisz, P, Pintér, I, Desi, I, Kádas, T *Lancet*, 1959, i 368

[3] Fehér, I, Dési I, Szold, E *Magyar Tudományos Akadémia V oszt Közleményei*, 1958, 9, no 3-4

After the third day both groups showed a distinct reduction in temperature and weight, and these changes were accompanied by diarrhœa for two or three days

The five series (taking into consideration the first 10 days) showed a significant 40% difference in survival in favour of the protected animals

By the fortieth day the protected animals and the controls showed practically no difference in survival A protected and a control animal of two series were killed and their organs examined *Histologically the testicles of the controls showed severe degenerative changes, whereas in the protected animals there were well-recognisable testicular ducts, good nuclear staining, and even spermatogenesis here and there*

Our observations so far and the difference in the histological appearance of the testes give reason to extend these experiments on a larger scale

Roentgenological and Urological Clinics,
University Medical School, Budapest

A NEW STEROID IN THE URINE IN NEPHROSIS

SIR,—In the course of steroid estimations a new reducing substance which behaves chromatographically like a corticosteroid has been found in the urine of untreated nephrotic patients

After 24 hours of mild acid hydrolysis at pH 1, the urines of 8 nephrotic children were extracted with chloroform After extraction the urines were incubated at pH 4 5 with 25 units per ml of calf-spleen glucuronidase for 48 hours, and again extracted with chloroform To purify them, the fractions were partitioned between benzene and water The materials from the watery phase were then run on paper in Bush's C chromatographic system [1] at room temperature

On spraying the paper with alkaline tetrazolium-blue solution, we found a reducing substance with R_f value of 0 58 (corresponding R_f values are hydrocortisone 0 3, cortisone 0 44, 11-desoxy-17-hydroxycorticosterone 0 65, corticosterone 0 75) The substance eluted from the paper was then acetylated and rerun in a system of hexan/benzene/methanol/water 4 1 4 1 The R_f value of the acetate was 0 29 (corresponding values hydrocortisone acetate 0 05, cortisone acetate 0 11, 11-desoxy-17-hydroxycorticosterone acetate 0 08, corticosterone acetate 0 07, aldosterone-21-monoacetate 0 07, aldosterone-18,21-diacetate 0 21)

The substance gives a positive soda-fluorescence test indicating the presence of a Δ^4-3-keto group, and *it is Porter-Silber negative, therefore does not contain a hydroxyl group on* C_{17} The prompt reaction to tetrazolium-blue suggests the presence of a ketol rather than a glycol side-chain, and the relatively high R_f value of the acetate suggests a diacetate form The substance is not identical with Nowaczynski's compound III [2] Its identity with Pasqualini's compound has not been investigated [3]

This steroid could not be demonstrated in nephrotic urine by only mild acid hydrolysis, nor could it be seen in the urine of healthy children even though it was subjected to hydrolysis with glucuronidase After suppression of the secretory activity of the patients' adrenals with prednisone or prednisolone, the substance disappeared from the urine in 4 cases studied

The purpose of our future investigations will be a more precise identification of this steroid and observation of the changes in excretion of the substance at different stages of this and other diseases

PREVENTION OF MIGRAINE IN CHILDREN BY PROCHLORPERAZINE

DR NEVIL LEYTON writes

" Contrary to what Professor Illingworth and Dr Harvey imply in their article of Jan 16, I have never made any claim that ' Stemetil ' alone is particularly useful in the prevention of migraine Indeed, I said [1] ' *many patients whom I have treated with it have either been unaffected or their headaches made worse, although I am glad to say that some have benefited*' The conclusions Professor Illingworth and Dr Harvey have reached simply confirm my own

" It has always been my opinion that no one scheme, and certainly no compound, will ever be of universal use in preventing attacks of migraine The compound which I have found most consistently of use, particularly when assisted by others, is chorionic gonadotrophin [2] "

Parliament

The Scottish Mental Health Bill

IN Scotland the law relating to mental health differs in many ways from English practice Its revision was considered by the Russell Committee which reported in 1946 [3] and a white-paper setting out proposals for its amendments was published in 1955 [4] Action was deferred until the English Royal Commission should report, and the Secretary of State for Scotland then invited the Scottish Health Services Council to consider the application of the Commission's main recommendations to Scotland The council has published two reports [5] from the committee which they set up for this purpose The Mental Health (Scotland) Bill, which has been prepared against this background, will have its second reading soon after Parliament reassembles Its main provisions are described in a white-paper [6] published by the Department of Health for Scotland

The Bill accepts most of the recommendations of the English Royal Commission—notably, that mental patients should have access to care and treatment without formality, that compulsion should be reduced to a minimum, and that the community mental-health services should be developed

In three important respects, however, the Scottish Bill departs from the English legislative pattern Throughout " mental disorder " is used as a general term to cover mental illness and mental deficiency and these are the only categories mentioned in the Bill

The Bill dissolves the General Board of Control for Scotland, but sets up in its place a Mental Welfare Board which will continue to carry out the old board's protective functions by investigating complaints and visiting patients in hospital or under guardianship The board will have not fewer than 5 members and not more than 7, of whom at least 2 must be doctors

The Bill also retains the services of the sheriff, a traditional Scottish legal officer who has no exact English counterpart Thus the sheriff must approve applications for compulsory admission (which must be signed by two doctors) The patient, or his nearest relative, has also the right of appeal to the sheriff against continued detention This procedure will take the place of the new appeal tribunals to be set up under the English Bill

The Scottish Bill places a specific duty (not provided under the present law) on the doctor in charge of the patient to discharge him if he no longer needs to be detained A similar duty is also placed on the new Mental Welfare Board (The nearest relative, or the hospital board or local authority concerned, may also discharge a patient) Courts will for the first time be given the power to remand in hospital instead of in custody people who seem to be mentally disordered

Notes and News

WORLD HEALTH ORGANISATION

ON Jan. 19 the Executive Board of W H O met in Geneva under the chairmanship of Prof E Aujaleu, director-general of public health, France By the end of November about 11½ million dollars had been contributed to W H O 's malaria eradication campaign. A further 8½ million dollars is needed to finance W H O 's malaria commitments up to the end of 1961

The canton of Geneva has now designated the property which it will place at the disposal of W H O for its new building, while the Swiss Parliament has authorised an interest-free loan to W H O of 20 million Swiss francs, repayable in twenty annuities

The regular working budget of the Organisation proposed for 1961 is 18½ million dollars

HINCHLIFFE RECOMMENDATIONS

THE Ministry of Health has been considering the report of the Hinchliffe Committee, and, with the agreement of the General Medical Services Committee, has commended to general practitioners (ECN 319) the recommendation that they should restrict the quantities of drugs they prescribe The Committee suggested that normally, except for chronic patients, the amount of drugs to be ordered on one prescription should not exceed one week's supply Other recommendations which the Ministry commends are that official titles should be used on prescriptions in preference to proprietary names, and that practitioners should avoid prescribing unnecessarily elaborate preparations The Committee's suggestion that new drugs should not be used in the National Health Service until they have undergone independent clinical trials is under consideration. Meantime doctors are asked, until the results of trials are known, to prescribe new drugs only if they are sure that existing drugs have failed It has been agreed with the professional bodies to produce a looseleaf handbook including much of the British *National Formulary* and facts about comparative costs of standard and proprietary preparations, and it is hoped to circulate copies to general practitioners soon The value of pre- and post-graduate training and education in prescribing is also stressed, especially arrangements for seconding medical students to general practitioners, refresher courses for practitioners, and the trainee practitioner scheme

MALNUTRITION IN AFRICA

AT Dar-es-Salaam on Jan 13, opening a scientific conference on the Origin and Effects of Malnutrition in Man and Animals, Sir Richard Turnbull, the Governor of Tanganyika gave highest priority to studies connected with infant mortality and infant malnutrition in the hope of removing ' those heavy handicaps of stunted physical growth and impaired intellectual development which so often result from early deficiencies in diet " Enormous areas of Tanganyika, he said, were infested with tsetse and as a result stock-farming in about two-thirds of the country was impossible The people living in and behind the fly areas suffered from a general protein deficiency, and he wanted to know whether this could be made good from vegetable sources alone and without reliance upon milk in any form

> " I feel that if we are to find a solution to this problem and not just a palliative, it must come from local resources, we cannot afford to be dependent on a supply of milk or some kind of animal protein concentrate from outside as a supplement to the diet

Prof B S Platt, in his presidential address, said that twenty years ago there was much talk of the " lazy African "—often coupled with talk about the need for incentives for him to better his lot.

> " I have always tended to associate indolence with ill-health When I first visited East Africa in 1938, I had fresh in my mind the contrast between the listless and apathetic, poorly fed apprentices in small factories in Shanghai and the noisy, mischievous and high-spirited ones who were well fed from a kitchen run under my supervision, and I found a similar contrast between groups of well and badly fed labourers in the goldfields in Tanganyika "

The morphological changes found in the central nervous system in animals in experimental malnutrition might, Professor Platt thought, have some relevance to certain mental disturbances in malnourished human beings

HOSPITAL MICROCOSM

MANY doctors who read the *Graver Tribe* were left with a feeling that they had involuntarily acquired a second medical school Those who have been awaiting further news about St Chad s will turn to Edward Candy's new book[1] to catch up with the gossip of what must surely be the wittiest and most civilised hospital in London. Nor will they be disappointed Within a few pages they will be *au fait* with the tussle for the old eye and tubercle wards on the top floor of the surgical block, alert to find out whether Clayton will successfully commandeer them for his burns unit or whether they will be given to Branksome as a temporary surgical home till his new unit is built

One of the reasons why we are so much absorbed by St Chad's is that the staff and their womenfolk, the patients and their relatives, show the same maddening mixture of good and bad, strength and weakness, generosity and meanness as our own friends or even ourselves This time Mr Candy has been content to avoid the interruption of near-melodrama and leaves us to follow the much more exciting manœuvre in committee, exchange at the hospital dance, or row in outpatients But the everyday never lapses into the trivial, for he recognises the universal issues behind the humdrum, respects diverse but sincere principles, and offers his own implicit, though never explicit, judgments

University of London

The following degrees have been awarded

M.D—John Burston A M Dawson, P J Koblenzer, A C K Lawrence, Ian Macdonald, J D Price

Ph.D (*in the faculty of medicine*)—Krishna Rao Yeommaji Rao Ghorpade

University of Aberdeen

Dr I B Porteous has been appointed a lecturer in pathology

University of Glasgow

The Bellahouston medals for 1959 have been awarded to W A J Crane, James Crooks, and A J S McFadzean

On Jan 16 the degrees of M B, CH B were conferred on Yuill Black (in absentia)

Monash University

Dr A J Marshall has been appointed professor of biology at this new university in Victoria, Australia

University College Hospital

Prof Montague Maizels will give the Sydney Ringer lecture at the Medical School, University Street, London, W C 1, on Tuesday, March 15, at 4.30 P M He will speak on salt and water balance in cells

World Health Day

The theme chosen for World Health Day for 1960 is Malaria Eradication—a World Challenge It will be held as usual on April 7

Partnership in Preventive Medicine

The Society of Medical Officers of Health and the College of General Practitioners will hold a postgraduate conference on July 16 and 17, at the medical school, University of Birmingham Further particulars will be given later

North of England Obstetrical and Gynæcological Society

The following officers have been elected for 1960

President, Prof T N A. Jeffcoate, vice-presidents, Mr J B Farquhar, Sir Arthur Gemmell, Miss E M Mills, Mr J M King, Mr J A. Hadley, hon treasurer, Mr T B FitzGerald, hon general secretary, Mr H V Corbett, hon reporting secretary, Miss U M Lister

---

[1] A Lady s Hand By EDWARD CANDY London Gollancz 1959 Pp 192 13s 6d

International Conference on Medical Electronics

This conference will be held at Olympia, London, from July 21 to 27 Further particulars may be had from the conference secretariat, Institution of Electrical Engineers, Savoy Place, W C 2

European Congress on Aviation Medicine

This congress will be held in London from Aug 29 to Sept 2 Further particulars may be had from the congress secretary, c/o British European Airways, Central Medical Clinic, London Airport (N), Hounslow, Middlesex

Rehabilitation of the Amputee

A course for orthopædic consultants and senior registrars will be held from March 28 to April 1 at the Limb Fitting Centre, Queen Mary's Hospital, Roehampton, London, S W 15 Applications should be sent to the Principal Medical Officer, Artificial Limbs and Appliances (Med 5 PL) at the same address

---

Prof A D Macdonald, president of the British section of the Franco-British Pharmaceutical Commission, has been appointed an officer of the Ordre de la Santé Publique by the French Minister of Health

The Yorkshire Society of Anæsthetists will hold their annual general meeting on Wednesday, Feb 10, at 8 30 P M at the General Infirmary at Leeds Dr W J Finnie will give his presidential address on the training and distribution of anæsthetists

The Group for Representation of the Views of Clinical Psychiatrists will meet on Tuesday, Feb 16, at 5 30 P M, at Tavistock House North, London, W C 1 The secretary of this group is Dr B C Gilsenan, Shenley Hospital, near St Albans, Herts

The National Institutes of Health have published a bibliography (*Publ Hlth Serv Publ* no 669) of papers published in English during 1952–58 about the effect on the offspring of the following disorders in the mother infectious diseases, diabetes, thyroid dysfunction, myasthenia gravis, lupus erythematosus, sickle-cell disease, thrombocytopenic purpura, leukæmia, drug addiction, and drug administration Statistical studies of perinatal morbidity and mortality are also included A limited number of copies are available from the library of the Institutes, Bethesda 14, Maryland Additional copies may be purchased from the Government Printing Office, Washington 25, D C (15 cents per copy)

Boarding-out Schemes for Elderly People—Copies of this booklet (1*s* 6*d*) may be had from the National Council of Social Service (26, Bedford Square, London, W C 1) It offers advice on how to run a boarding-out scheme and includes a brief survey of information drawn from existing schemes sponsored by voluntary bodies and local authorities

'Versenate', mentioned in the paper by Dr Miller and Dr Smith (Jan 2), is a trade mark of the Dow Chemical Co, and Riker Laboratories Ltd are registered users

EARLY TREATMENT OF STOVE-IN CHEST*

N R Barrett
M Chir Cantab., F.R.C.S.
SURGEON, ST THOMAS'S HOSPITAL, LONDON, S.E.1,
AND BROMPTON HOSPITAL, LONDON, S.W.3

A "stove-in chest" results from multiple rib fractures or from disruption of the costosternal cartilages; it is often complicated by other injuries, but its peculiar feature is paradoxical movement of the chest wall at the site of the fractures.

Paradoxical movement causes asymmetrical expansion and contraction of the thoracic cage, and this, in its turn, produces inadequate absorption of oxygen and elimination of carbon dioxide from the alveoli. These patients die from "respiratory failure" and not because a few bones have been broken. The purpose of this paper is to underline the fact that some who now die can be saved by simple treatments.

The perfection of fast touring cars and the construction of modern motorways have made these injuries common, but few surgeons are, as yet, experienced in the emergency treatments that may be vital. The victim is hurried away to the nearest hospital where he dies or survives almost irrespective of the things that may be done for the chest injury. A thoracic surgeon seldom sees the patient unless he survives for at least 48 hours, and so it behoves those responsible for the reception of accident cases to acquaint themselves with measures that are easy and effective.

Nature of the Injury

This type of chest injury occurs when the hoops composed of vertebral column, ribs, cartilages, and sternum are suddenly compressed. The direction of the forces that fracture the ribs is often an outward burst at the weakest parts of the hoops—as opposed to the local inward thrust of direct violence. Paradoxical movement can be recognised by looking at the chest wall as the patient breathes or, if this is not practicable, by palpation.

The critical extent of such an injury varies from patient to patient; the young tolerate more than the aged, and every moment the patient survives is time gained in his favour. If an injured person reaches a hospital alive respiratory failure should still be reversible, but minutes count.

An acquaintance with the management of thoraco-abdominal injuries sustained in war is not an adequate background for this work. The complications of stove-in chest are different. The importance of peritonitis and intra-abdominal hæmorrhage is eclipsed by concomitant head injuries and fractures of the long bones, vertebræ, and pelvis, and by complicating factors in the chest itself, as well as distension of the stomach and ileus.

Patients with multiple injuries, including "a stove-in chest", often die without obvious cause. Hæmorrhage has been stemmed, transfusions have been given to combat shock, and ample morphine has relieved the sharp edge of the pain. The sedated patient lies quietly in bed and his shallow paradoxical respiratory movements escape critical notice. But death steps in suddenly, peacefully, naturally—and unnecessarily.

The accurate assessment of everything that contributes to this outcome is difficult, but, considering chest-wall injuries alone, the following points are relevant.

Paradoxical movement of the chest wall, uncomplicated by any serious intrathoracic injury, can be fatal. It was the principal cause of death in the early days of thoracoplasty. The harm it does is comparable to that of open pneumothorax, but of lesser degree in most cases. The flail area is sucked in as the chest expands, and blown out during expiration. The result is that some of the air that should be exchanged by passing in and out of the lungs, is shunted from one side of the chest, or from one part of the lung, to another. In severe cases this movement of air displaces the mediastinum to and fro during respiration, and this used to be called "pendulum movement". It was considered to be dangerous because it was said to hinder blood returning to the right atrium; it *is* dangerous because it produces asphyxia.

It has been shown by bronchospirometry that a single, simple, rib fracture causes, reflexly, a measurable reduction of gas exchange in the lungs. This is due to a partial shut-down in the pulmonary vessels supplying the underlying lung. It is not of clinical importance if the patient's reserve of compensation is not seriously affected. But in severe injuries the resultant reflex pulmonary hypertension can eliminate gas exchange completely in all or part of a lung, and this happens even though the respiratory movements continue.

Pain upon respiration adds to the oxygen deficit by reducing the excursion of the chest wall and so by diminishing the volume of tidal air. Cough is suppressed because it hurts, and reflex spasm of the bronchial muscles contracts the lumen of the respiratory passages.

The patient has increasing difficulty in getting rid of bronchial and alveolar exudates, and the development of a "wet lung" is Nature's last cry.

Why secretions first accumulate in the bronchial tree is not clear. But it is certain that in the early hours after serious accident pulmonary œdema occurs, and this has been explained in several ways. Possibly the shut-down in the pulmonary vessels underlying an injured chest wall could cause anoxia and œdema of the affected alveoli. Alternatively the sudden diversion of a large proportion of the cardiac output might initiate hyperkinetic œdema in the sound lung. Cardiac failure and cerebral injuries may also play a part, and over-transfusion is a risk. Be these things as they may, the casualty surgeon must know that pulmonary œdema and retained bronchial secretions can kill within an hour of an accident, even though the lung itself has not been directly wounded. Moreover, the presence of bloodstained, watery expectoration is not necessarily due to a lung wound.

If a patient survives the initial risks of early pulmonary œdema, the retained secretions may become infected during convalescence and "bronchopneumonia" sets in. This should be preventable.

In addition to ventilatory difficulties the position is frequently aggravated by a lung wound, by intrapulmonary or intrapleural hæmorrhage or pneumothorax, by hernia if the diaphragm has been ruptured, or by acute dilatation of the stomach. Any, or all, of these can make breathing impossible.

---

[*] An address to the Society of Thoracic Surgeons of Great Britain and Ireland, Newcastle upon Tyne, November, 1959.

A major chest injury causes temporary restriction of the diaphragmatic excursions on the affected side The dome of the diaphragm is always high

A patient who has a “ stove-in chest ” and who reaches hospital alive is living on his pulmonary reserve He now faces the additional hazard of being given morphine or other respiratory depressants

The harmful effects of anoxia are cumulative and ultimately become irreversible

Treatment

In the care of a patient with multiple injuries including a “ stove-in chest ”, attention cannot be confined to the chest injury, but in the first few hours treatment of this injury takes precedence over everything except primary hæmorrhage

As a whole such treatment falls into three periods during which the aims are different Immediately after the accident, and during the next 48 hours, the object is to correct inadequacies in the act of respiration In those who survive, pulmonary infections must be forestalled, and total expansion of the lung on the affected side achieved and maintained During convalescence normal movements of the chest wall and diaphragm must be regained

The advice that follows concerns the emergency treatment only

When a patient who has a “ stove-in chest ” and respiratory difficulty is admitted, give an anæsthetic, pass a cuffed intratracheal tube, and start controlled respiration The anæsthetic is necessary to allow respiration to be controlled—and it is the latter that is important, not the former Respiratory efforts by the patient can be abolished by producing alkalotic apnœa, by giving paralysing drugs, or using a combination of both Intubation and controlled respiration saves life and has the additional advantage of enabling secretions to be sucked out of the air passages as often as they accumulate

Experience in the treatment of recently wounded people during the late war, and particularly with young and otherwise healthy adults, showed that the critical state in which they were admitted to hospital was often due to inefficient respiration As soon as the anæsthetist took over control of the act of breathing the clinical state improved, and, if the surgeon could then remedy the anatomical defects, so that spontaneous respiration could be resumed, the “ come-back ” was rapid and simple

Once the patient has been anæsthetised in the outpatient department, the other injuries can be examined and a plan of campaign adopted This is the moment to decide whether early operation of any type is necessary or not

As far as the chest wall is concerned, determine the extent and position of the unstable areas, and examine the patient to discover other complications If the anæsthetist, giving controlled respiration, cannot achieve easy movements on the affected side, the assumption should be that there is an intrathoracic complication The usual reason why the affected lung cannot be inflated easily is that it is artificially restricted by pneumothorax, tension pneumothorax, blood in the pleural cavity, gastric dilatation, or diaphragmatic hernia

It is not easy to be certain about any of these things clinically, and it may not be safe at this time to sit the patient up for an X-ray of the chest (a film taken in the recumbent position is confusing), but the following details may help Observe the position of the apex beat, and remember that if breath sounds can be heard anteriorly, in the recumbent patient, an important pneumothorax is not present Hæmothorax is particularly difficult to diagnose because, at this stage, the blood moves in the pleural cavity according to the position of the patient (“ shifting dullness ”) Thus, lying down, the lung floats forward on the blood in the paravertebral gutter and breath sounds are heard over the front of the chest, conversely when the patient sits forwards there are breath sounds at the back For this reason a hæmothorax of several pints can be missed, unless the patient is examined, recumbent, with a flat stethoscope slipped in between the chest and the bed The only way of diagnosing acute dilation of the stomach or diaphragmatic hernia at this stage is by an appropriate X-ray

If the patient has, in addition to a stove-in chest, a hæmothorax, put an intercostal catheter into one or both pleural cavities and connect these to water-seal drainage bottles The usual causes of traumatic hæmothorax are bleeding from the chest wall and, more rarely, from the lung, but in these days of rapid deceleration accidents rupture of the intima and media of the aorta is not uncommon In such cases a false aortic aneurysm develops with oozing into the pleural cavity, they may live for as long as two months before the aneurysm bursts If there is pneumothorax or tension pneumothorax, insert a small polyethylene tube, using a hydrocœle trocar, into the top of the affected pleural cavity through the second or third interspace anteriorly, connect the tube to a sealed drainage or suction apparatus These emergency safety-valves can be maintained for two or three days without risk of intrathoracic suppuration, by this time definitive treatment will have been given and the tubes will have been replaced, or taken out There is no merit in tubes that are blocked by clots in the lumen or by kinks in the dressings If a pneumothorax or tension pneumothorax persists in spite of adequate continuous suction, rupture of a main bronchus should be suspected and, if present, treated by thoracotomy without delay

Cardiac tamponade is a rare complication of stove-in chest, but if it be suspected the pericardium should be tapped by passing a long needle from the side of the xiphisternum upwards and backwards for a distance of about 10 cm Blood that restricts the movements of the heart accumulates behind the ventricles and can be aspirated without difficulty A misdirected tap is not dangerous because the needle approaches the least vascular part of the heart—that is, the apex

The above measures may be necessary in the accident department They are simple and, once completed, a proper assessment of the other injuries can be made without danger to the patient The emergency time is over

The surgeon must now decide how efficient respiration is to be maintained, and this decision is difficult It will be obvious that if other treatments, such as traction for a fractured femur, are to be used, the management of the chest from now onwards must be unobtrusive and effective

The first decision to take is whether the flail chest wall should be stabilised by local treatment, and several alternatives are available

The first of these is to pad and strap the affected area Do not do this, for these reasons Strapping is easy to apply but difficult and painful to take off, the man who puts it on seldom has to take it off and, consequently, he does not shave the skin It is a wasteful way of preventing paradox because, to be effective, the strapping must immobilise a much wider area than has been damaged It may augment the respiratory inefficiency by fixing parts of the chest wall that would otherwise move effectively It makes X-rays difficult to interpret, and it hinders aspirations of the pleural cavity It has no merit except ease of application

There are a variety of minor operations that can be done under local anæsthesia and help some forms of paradox The sternum can be elevated and held by traction applied to a cuphook screwed into the body of the bone and attached, over a pulley, to an appropriate weight This can be effective

The fractured ribs can be elevated and held by inserting several towel clips through the skin and around the mobile parts of the ribs, and applying traction in an outward direction

Two or more Steinmann pins can be inserted under local anæsthesia, and through tenotome punctures in the skin, so that they cover the defect in a criss-cross fashion like boards nailed across a broken window The pins rest upon the intact ribs and should be deep to the sheet muscles of the shoulder girdle

These are temporary expedients, and are seldom used because they are not sufficiently good But some surgeons are convinced of the necessity to stabilise the chest wall and they advocate open operation for the purpose

To succeed in such a treatment it is necessary to elevate a wide flap of skin and muscles in the affected area and, having laid the fractures bare, to fix all the broken ribs—fore and aft—so that absolute stability is achieved To do this one must use intramedullary pegs or wire the fragments in two planes The operation is not difficult, but it takes time Once completed there are no external splints or traction appliances to complicate treatment, and the intrathoracic injuries have been accurately assessed at the same time by opening the pleura and examining the thoracic viscera An operation of this type eliminates paradoxical movement once and for all, and it prevents late persistent deformity of the thorax It is true that, if it is not done, the late result of a stove-in chest may look like a lateral thoracoplasty and carry the attendant limitation of respiratory function in after-life Many successes have been reported

But, in general, these operations are seldom used, and for these reasons They take time and add to the shock of the existing injuries It requires mature judgment to balance the possible benefits against the trauma of the additional manipulations, and the problem of how to control bronchial secretions remains Fortunately alternative treatments are available

Whenever paradoxical respiration is so severe that it must be controlled, a tracheostomy should be done Borrie says "the time to do a tracheostomy is when considering whether or not it should be done"

The operation is best done whilst the patient is under the anæsthetic given on admission, and whilst the anæsthetist's cuffed tube is in the trachea It is simple and accurate to cut down upon a trachea splinted in this way, and to insert a plastic tracheostomy tube on which there is distensible balloon The balloon need not be inflated, or used, until the result of tracheostomy has been assessed

The benefits of tracheostomy are that, by diminishing dead space, the patient need not breathe so deeply to ventilate, secretions can be sucked out, oxygen can be given as occasion demands, and obstruction from paralysis of the tongue is eliminated And mechanical respiration can be started if necessary

Ingravescent surgical emphysema is a distressing complication of chest injuries In general it signifies that the lung has been ruptured in one or more places, or it complicates an open pneumothorax that has sealed off, coughing then injects the air, trapped in the pleural space, into the subcutaneous tissues of the chest wall or into the mediastinum and the neck A tracheostomy controls, prevents, and eliminates surgical emphysema

It is an unexpected but commonly observed fact that by doing a tracheostomy, and nothing more, the problems of inefficient respiration are solved in many cases This is particularly true in elderly or bronchitic subjects

When repeated toilet of the air-passages, by catheter suction is used, *sterile* catheters must be available for the purpose If this precaution is not taken the patient will probably be given staphylococcal pneumonia, or may acquire an equally intractable organism This type of complication can determine the issue

If tracheostomy by itself fails to control the harmful effects of paradoxical movement, or if other complications, such as coma due to an associated head injury, demand more definite measures to ensure efficient respiration, the balloon on the intratracheal tube can be inflated, and the patient connected to a breathing-machine If this decision has been taken the outlook is serious but not by any means hopeless There are few circumstances, excluding severe lung or vascular injuries, in which efficient respiration cannot be continued for as long as may be necessary These patients can be kept alive But prolonged controlled artificial respiration is not to be lightly pursued by all and sundry, and at this stage the patient should probably be transferred to a unit that specialises in this work If necessary artificial respiration can be continued in the ambulance whilst the patient is transferred to a respiratory unit, using the hand bellows that are now available

After tracheostomy, or other definitive treatments, steps must be taken to alleviate pain The danger of giving morphine, or its derivatives, is stressed by almost everybody who has treated these patients It depresses cough, encourages retention of bronchial secretions, and favours the development of septic pneumonia The best alternative is to inject local anæsthesia into the vicinity of the fractures A single injection may not be enough, but the effects often last longer than one expects If chest-wall pain continues, a small polyethylene catheter can be introduced into the traumatised area and through this small but adequate amounts of local anæsthetic and antibiotic can be instilled as necessary

Conclusions

The immediate procedures advocated in this paper and purporting to control the dangerous effects of "stove-in chest" are simple

The battle that must be won during the first few hours, and the position that must be held for subsequent days or weeks, is against anoxia and carbon-dioxide retention

Strapping the chest wall, morphine, and barbiturate sedatives are contraindicated The use of "Drinker type" respirators is bad because they compress the flail chest wall

The procedure, on admission to a hospital, that I recommend in cases of respiratory embarrassment due to "stove-in chest" is this

1 Anæsthetise the patient straight away in order to achieve controlled respiration.

2 Examine the patient and assess the relative priorities of multiple injuries

3 Eliminate the additional burdens of hæmothorax, pneumothorax, tamponade, dilatation of the stomach, or

diaphragmatic hernia, by appropriate catheterisation, sealed drainage, or suction.

4. Improve the efficiency and ease of respiration by tracheostomy if necessary.

5. Institute controlled respiration using a mechanical breathing machine in desperate cases.

6. Control pain by local injections of anæsthetic solution. Do not give morphine unless or until efficient respiration is assured.

If, after tracheostomy, it be decided that a mechanical breathing machine must be used, adequate apparatus and personnel must be available. A patient kept alive artificially in this way requires constant medical and nursing care, at least in the early days of treatment.

The high mortality associated with " stove-in chest " is due to cardiorespiratory failure, and notably to anoxia and carbon-dioxide retention.

PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LONDON

From the Department of Medicine, Postgraduate Medical School, Hammersmith Hospital, London, W 12

SUCCESSIVE advances in the treatment of high blood-pressures have been made possible by the steady output of new and improved drugs. Until recently all the really potent drugs acted by blocking the autonomic ganglia. Pressure reduction was invariably accompanied by partial paralysis of the parasympathetic system with consequent dry mouth, blurred vision, constipation, and impotence. In some patients episodes of paralytic ileus threatened life, particularly when renal function was impaired. Because of these difficulties only the most severely ill were selected for treatment. The severity of side-effects varied greatly from patient to patient, but only a minority were unable to tolerate the regime. All patients, however, had to endure inconvenience and even at times incapacity from the drugs and this made it difficult to achieve optimal pressure reduction in all. The elimination of these parasympathetic side-effects would clearly be a desirable contribution by improving the toleration of treatment.

The first lead towards a drug of this type was TM10 (Hey and Willey 1954), which had a selective paralytic action on the postganglionic adrenergic neurones but unfortunately also stimulated parasympathetic fibres—a property which made it useless therapeutically (Bain and Fielden 1957). Recently a much more promising drug, bretylium tosylate ('Darenthin'), has been described (Boura et al. 1959). This drug paralyses adrenergic neurones without significant effect on the parasympathetic system. These workers reported the results of treatment in 36 patients with hypertension, and in every patient except 1, who had a phæochromocytoma, pressure reduction was achieved. In 4 patients the treatment had to be stopped because of symptoms associated with postural hypotension. Side-effects were trivial, and the only one of importance was stuffiness of the nose. In view of this encouraging report we have employed bretylium in the treatment of severe hypertension, at first only in those suffering severely from side-effects of ganglion blockade and later in a number of new patients receiving treatment for the first time. The main difficulties encountered resulted from the variability of the degree of fall of blood-pressure, and studies of absorption were made to clarify this problem.

Patients and Methods

A total of 50 patients were given oral maintenance treatment with bretylium during the six-month period of this trial. 28 of them had previously been treated with ganglion-blocking drugs, usually pempidine or mecamylamine. Initially only those patients with very severe side-effects or poor control of blood-pressure were transferred from the ganglion-blocking drugs, but later some with less severe side-effects were switched to bretylium. All the patients had severe hypertension and 22 had hæmorrhages, exudates, or papillœdema in the retina when treatment had first been started. Other indications for treatment included: hypertension with chronic renal disease, hypertension in pregnancy, hypertensive heart-failure, and severe high pressure and symptoms.

All the patients were admitted to hospital for stabilisation on bretylium. 5 patients were first treated with intravenous doses of bretylium because acute reduction of the blood-pressure was required. Intravenous treatment was unsatisfactory, and subsequently all patients were treated with the 200 mg. oral tablets of bretylium tosylate. The usual starting dose was 600 mg. daily given as one tablet after breakfast, lunch, and supper. The dose was increased daily by 300 to 600 mg. until a satisfactory fall in the pressure was achieved. In hospital the blood-pressure was recorded with the patient lying down and standing up at least four times daily. Patients with malignant hypertension or left ventricular failure were nursed propped up on pillows and with the bed head raised on 12 in. blocks. Less severely ill patients were encouraged to sit in chairs or walk about the ward as much as possible. Outpatients were seen at short intervals in a special clinic for hypertensive patients.

Absorption Studies

Bretylium labelled with ^{14}C was available as a sterile solution containing 5 µC of radioactivity with 30 mg. of bretylium iodide for intravenous use and 5 µC with 200 mg. bretylium tosylate for oral use. The maximum dose approved for use in patients was 5 µC because of the long half life of ^{14}C. As the permissible dose was small measurements had to be confined to the excretion in the urine after oral and intravenous doses. The twenty-four-hour excretion after an oral dose was measured in 10 fasting patients. 6 other patients were studied on two separate occasions to compare the eight-hour excretion. The twenty-four-hour excretion of bretylium after intravenous doses was measured in 6 patients, 4 with normal renal function and 2 with blood-urea values of about 120 mg. per 100 ml.

^{14}C was counted in a liquid scintillation counter (Jones et al. in press). 1 ml. urine samples were added to the toluene-alcohol-scintillator mixture and counted directly. Errors from quenching due to other constituents of urine were avoided by counting the standards in the presence of equal quantities of the same urine samples.

Results

ABSORPTION AND EXCRETION STUDIES

Intravenous Doses

The total excretion in twenty-four hours following an intravenous dose is tabulated in table I. The recovery in

TABLE I—TWENTY-FOUR-HOUR EXCRETION AFTER INTRAVENOUS ^{14}C BRETYLIUM DOSES

Case no.	Blood urea (mg. per 100 ml.)	24 hr. excretion (%)
1	37	65
2	40	60
3	36	83
4	32	74
5	115	23
6	120	31

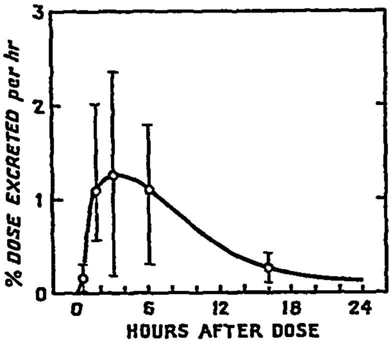

Fig 2

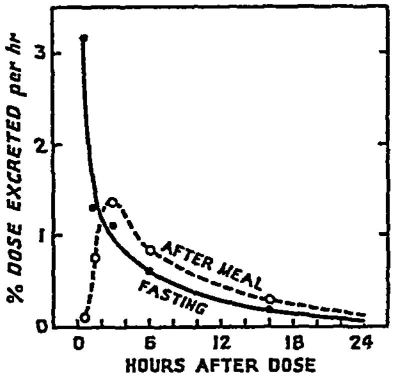

Fig 3

Fig 1—Fractional excretion of ^{14}C bretylium for 24 hours following intravenous administration in 4 hypertensive patients with a normal blood-urea and 2 with a blood-urea of about 120 mg per 100 ml Open circles indicate mean excretion in patients with a normal blood-urea and closed circles the uræmic patients The vertical lines show the range

Fig 2—Fractional excretion of ^{14}C bretylium in 7 patients given oral doses while fasting The circles indicate the mean excretion per hour at the midpoint of each collection period, and the vertical lines show the range

Fig 3—Fractional excretion of ^{14}C bretylium in a patient who showed a rapid initial excretion after a fasting dose and was given a second dose after a meal

the 4 patients with normal blood-urea ranged from 65 to 83% with a mean of 71% The 2 patients with a raised blood-urea excreted only 23% and 30% The fractional excretions of these 2 patients are compared with those of the other 4 patients in fig 1

Oral Doses

10 patients were given 5 µC oral doses of bretylium while fasting and the excretion was measured over the following twenty-four hours The total excretion ranged from 5 1% to 18 3% with a mean of 12 9% (table II) The lowest excretion was from a patient with a blood-urea of 74 mg per 100 ml , another with a blood-urea of 79 mg per 100 ml excreted 14 6% of the dose in twenty-four hours The renal functions of the other patients may have been slightly impaired but the blood-urea concentrations were within the normal range The fractional excretion was measured in 8 patients, and in 7 it showed a similar pattern (fig 2) Excretion was maximal between the second and eighth hours after the dose, but in 1 patient there was much more rapid initial excretion although the twenty-four-hour excretion was only 11 6% This patient was restudied with the dose given after a meal, and the excretion then conformed to the more usual pattern (fig 3)

Paired absorption studies were made in 6 patients The eight-hour excretion was compared when the dose was given fasting and again after a meal Absorption was greater when the dose was taken fasting (table III)

These studies have proved the incomplete and probably irregular alimentary absorption that has a considerable bearing on the problems of treatment

TREATMENT OF HYPERTENSIVE PATIENTS

Intravenous Doses

4 patients with left ventricular failure and 1 with acute nephritis and hypertensive encephalopathy were treated with intravenous doses of bretylium iodide ranging from 200 to 600 mg 1 patient with left ventricular failure had a satisfactory fall in blood-pressure, but the other 4 patients did not All the patients were nauseated immediately after the injection and 4 of them vomited This happened despite dilution of the dose 10 1 in 5% dextrose before injection.

TABLE III—EIGHT-HOUR URINARY EXCRETION AFTER ^{14}C BRETYLIUM ON TWO SEPARATE OCCASIONS

20	0 1	8·4
21	9 6	16 0
22	4 1	6 7

Oral Maintenance Treatment

50 patients were started on oral maintenance treatment with bretylium tosylate The final dose which controlled the pressure ranged from 200 mg to 3600 mg daily with a mean of 1800 mg In 6 patients blood-pressure could not be controlled even with the largest doses It is difficult to analyse concisely all the results obtained in this large group of patients To facilitate presentation the patients have been divided broadly into those with a satisfactory result and those who were unsatisfactory

Patients referred to as *satisfactory* had at least a 20 mm. Hg fall in the diastolic blood-pressure on standing or a standing pressure of 160/90 mm. Hg or lower

Patients listed as *unsatisfactory* had either little reduction of blood-pressure or were intolerant of the drug in some way

These data are shown in table IV with the hypertension divided into different groups A striking feature is the poor results obtained in the patients with malignant hypertension, only 3 out of 11 were satisfactory However, the patients without retinitis or papillœdema showed a much more favourable response, 21 out of 28 were satisfactory The arbitrary division into satisfactory and unsatisfactory conceals all gradations from excellent to

TABLE IV—RESULTS OF TREATMENT WITH ORAL BRETYLIUM

Indication for treatment	Satisfactory	Unsatisfactory	Total

Hypertension in pregnancy	1	2	3
All causes	30	20	50

disastrous, but it does convey the overall picture without much distortion. Many of the patients who had previously been treated with ganglion-blocking drugs were deeply grateful for the freedom from constipation, and for some the change was so dramatic that they were almost lyrical in their praise of bretylium. A number of young hypertensives treated from the beginning with bretylium showed an excellent response and the drug seemed to interfere very little with their daily life.

Causes of Treatment Failure

The high proportion of unsatisfactory responses in the malignant group makes it worth while to examine them in more detail. The 3 responses regarded as satisfactory included the only 2 malignant hypertensives treated with bretylium from the beginning. Both these patients have shown regression of hæmorrhages, exudates, and papillœdema with treatment. The 3rd had rather less satisfactory control of blood-pressure, but he developed a subacute dissecting aneurysm of the aorta and died of uræmia. There is no reason to incriminate this particular drug in this disaster. The 8 patients with malignant hypertension whose response was unsatisfactory had all been treated previously with ganglion-blocking drugs and had proved difficult to manage. 5 of them were not controlled by large doses of bretylium (2400–3600 mg daily) with added chlorothiazide and had to be transferred to other drugs; 2 of them subsequently died of uræmia and the other 3 are at present being treated with pempidine. 2 of these patients initially responded to moderate doses of bretylium, and the 3rd, who was having 3600 mg of bretylium daily, had one severe fall of pressure although it remained very high on numerous other occasions. Of the remaining 3 patients 1 is being treated with a combination of bretylium and pempidine and the other 2 are inadequately controlled by bretylium at present but have not reached maximum doses.

Among the less severe hypertensive patients there were fewer failures, and most of these were caused by fluctuations in the pressure-lowering action. 2 patients had minor strokes and 1 a myocardial infarction during periods of low pressure; fortunately all 3 recovered completely. Abrupt falls of pressure are a serious hazard in patients with vascular disease of the brain or myocardium, and they seem to occur more commonly with bretylium than with the more regularly absorbed pempidine or mecamylamine. Several patients who had been accustomed to ganglion-blocking drugs complained of a feeling of insecurity with bretylium because they could not predict when postural hypotension might occur. For this reason 3 of them asked to return to ganglion-blocking drugs even though in other respects they preferred bretylium.

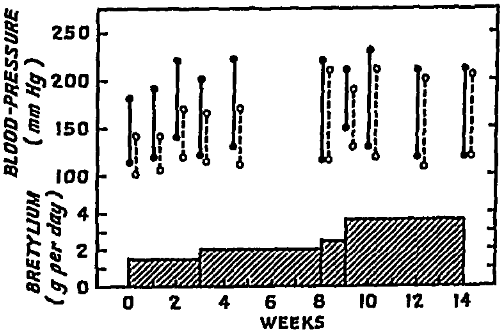

Fig 4—Standing and lying blood-pressures 2 hours after the morning bretylium dose at intervals over a period of 14 weeks in a patient with malignant hypertension.

Tolerance

Minor degrees of tolerance may have passed unnoticed while the dose was slowly increased to gain control of the blood-pressure. Over longer periods a number of patients required increasing doses to secure the same reduction of blood-pressure. 1 such patient was well controlled with 1500 mg daily at the beginning, but over the succeeding three months required a progressive increase to 3600 mg daily (fig. 4), when this dose proved ineffective the patient had to be transferred back to pempidine. Fortunately most patients have required only moderate increases, but the margin between present dosage and the maximum daily intake of, say, 18 tablets is small.

Side-effects

Many patients noticed mild nausea with oral bretylium, and 2 uræmic patients were troubled by both nausea and vomiting which ceased when the drug was stopped. Nasal stuffiness was frequently present but only 2 patients volunteered complaints about it. 2 patients complained of tightness of the skin around the nose and lower eyelids, and in 1 this was associated with severe nasal stuffiness. 4 patients noticed tenderness of the parotid gland at the angle of the jaw, especially when eating. 3 patients noticed visual impairment; in 2 of them objects close up seemed blurred, perhaps owing to accommodation difficulty, and the other noticed undue brightness of vision at a time when the pupil was small—for which we have no explanation. 1 patient developed a fine papular erythematous rash which disappeared when bretylium was stopped. When broken tablets had to be given some patients complained about the very bitter taste. About two-thirds of the patients, however, were not subjectively troubled to any important extent.

Deaths

5 patients who had been treated with bretylium died during the period of this study. 2 died of uræmia, 1 of a dissecting aneurysm, 1 of cerebral hæmorrhage, and 1 of polyneuritis of the Guillain-Barré type.

Discussion

Our experience with bretylium suggests some general conclusions about its place in the treatment of severe hypertension. Bretylium is an effective drug which has a low incidence of serious side-effects. It is probably the drug of first choice for "benign" hypertensive patients without ischæmic vascular disease who are being treated for the first time. In patients with cerebral or myocardial ischæmia a fully-absorbed drug such as pempidine or mecamylamine is probably safer. Any potent hypotensive drug may, rarely, precipitate a stroke or myocardial infarction in patients with occlusive vascular disease, but the risk is greater with a drug such as bretylium which gives rise to occasional unpredictable severe falls of blood-pressure Some of the fluctuations in the hypotensive action of bretylium must be the result of variable absorption This is to be expected with any drug which is poorly absorbed from the gut, because small changes in the proportion absorbed (say from 6 to 12%) may cause relatively large changes in the pharmacological effect The results for the excretion of bretylium after oral and intravenous doses are comparable with the results obtained by Milne and Oleesky (1951) and Harington (1953) in studies with the quaternary-ammonium ganglion-blocking drug, hexamethonium. The only important difference is that the mean twenty-four-hour excretion of bretylium after oral doses is 12 9%, whereas for hexamethonium it is 5 4% As the absorption of bretylium is appreciably greater than that of hexamethonium, fluctuations in absorption could be less dangerous The patient who showed a very rapid initial absorption after a fasting oral dose of bretylium is of interest because this may account for sudden falls of pressure observed in some patients The paired eight-hour excretion studies showed that the absorption after a fasting dose was always greater than after a meal The slow excretion of bretylium after intravenous doses in patients with uræmia emphasises the need for care with these patients, who may accumulate the drug over several days and then become suddenly and persistently hypotensive 1 such patient was faint on standing for five days after stopping oral bretylium

Patients with severe hypertension, particularly malignant hypertension, required large doses of bretylium to control the blood-pressure When bretylium proved ineffective in maximum doses the addition of chlorothiazide or strict sodium restriction caused a moderate increase in the hypotensive action More than half (13 out of 22) of the severe hypertensives were not controlled by these measures and had to be transferred back to ganglion-blocking drugs Some of these patients were at first controlled by bretylium but became unresponsive after weeks or months Tolerance of this kind is a serious problem because the difference between the effective dose and the maximum dose is often small. There is a real need for a drug which retains the pharmacological specificity of bretylium but which has a greater activity per unit weight.

The overall results of treatment with bretylium in our series were less good than those recorded by Boura et al. (1959) and by Smirk and Hodge (1959) There are two possible explanations of this discrepancy Our series contained a high proportion of very severe hypertensives and a number of patients who had responded poorly to large doses of ganglion-blocking drugs These patients proved to be relatively insensitive to bretylium. The second possibility is that longer follow-up has revealed a larger number of patients in whom bretylium is becoming less effective

In the present trial patients who had retinal hæmorrhages, exudates, or papillœdema fared badly when they were treated with bretylium. It is, therefore, inadvisable to switch such patients to bretylium if their blood-pressure is well controlled by other drugs If patients with retinitis have side-effects which are so severe that pressure control has to be relaxed it may be useful to try them on bretylium Patients without retinitis or papillœdema can be transferred without much difficulty, and less severe side-effects may make the change desirable.

Bretylium is a step forward along a difficult road It allows control of blood-pressure in many patients without some of the miseries that accompanied ganglion blockade, but it is less reliable than pempidine or mecamylamine as a pressure-lowering agent The reduction of blood-pressure is brought about by sympathetic paralysis and in consequence the management of the patient on bretylium is very similar to that of patients on ganglion-blocking drugs Frequent follow-up and careful adjustment of the drug dose are essential if good results are to be sustained

Summary and Conclusions

Bretylium tosylate facilitates the management of hypertensive patients on long-term oral treatment because of the low incidence of side-effects The best results were obtained in hypertensive patients without retinal hæmorrhage, exudates, or papillœdema, and in this group 75% showed a satisfactory response. Only 41% of the patients with retinitis or papillœdema were satisfactorily managed The malignant hypertensive patients who had been difficult to manage with pempidine or mecamylamine usually proved insensitive to oral bretylium in the doses used in this trial

10 hypertensive patients given ^{14}C-labelled oral bretylium excreted a mean of 12 9% of the dose in twenty-four hours 4 hypertensive patients given intravenous doses excreted a mean of 73% in twenty-four hours Irregular and incomplete absorption after oral administration probably contributed to the variable falls of pressure in some patients Such unpredictable falls of blood-pressure are dangerous in patients with occlusive vascular disease of the brain or heart

We should like to thank Dr David Long, of the Wellcome Foundation, for supplies of labelled bretylium.

THE association of polycythæmia with renal carcinoma has now been reported in over 30 patients, and the subject has been reviewed by Damon et al (1958) and Forssell (1958) The occurrence of polycythæmia with renal tumours other than carcinoma has been described in 2 cases (DeMarsh and Warmington 1955, Lawrence and Donald 1959) Where nephrectomy has been possible long remissions of the polycythæmia have occurred in some cases

Recently there have been a few reports of polycythæmia with non-neoplastic renal lesions, polycystic kidneys were present in 4 of these cases (Forssell 1958) and hydronephrosis in 3 (Cooper and Tuttle 1957, Gardner and Freymann 1958, Lawrence and Donald 1959) This combination is probably commoner than the few reports of it would suggest, thus Kurrle (1954) described as a case of Gaisbock's syndrome a patient in whom polycythæmia and hypertension were associated with polycystic kidneys In 5 of these 8 cases the diagnosis of polycythæmia was established by measuring the total red-blood-cell volume indirectly by plasma-volume/hæmatocrit methods In 1 case it was shown that the red-cell volume diminished after nephrectomy

We report here 2 cases of polycythæmia associated with non-neoplastic renal disease In both patients polycythæmia disappeared after nephrectomy

The relationship between renal disease and excessive erythropoiesis acquires added significance in the light of experimental work implicating the kidney as one possible source of erythropoietin (Jacobson et al 1957, Osnes 1958) In the 2 cases reported here plasma-erythropoietin levels were initially elevated and fell to normal after nephrectomy

Methods

Red-cell volume was measured by the ^{51}Cr method (modified from Veall and Vetter 1958)

Plasma volume was determined with an Evans-blue dye technique

Lean body mass—For reasons discussed later red-cell volume was related to lean body mass (L B M) The latter was calculated from the total body-water (T B W) using the relationship $\frac{\text{T B W}}{0\ 73} = \text{L.B M}$ (Pace and Rathbun 1945) The volume of distribution of administered urea was considered to measure T B W (McCance and Widdowson 1951) Three estimations of the urea space were made on each occasion (Prunty et al 1959)

Iron metabolism—Plasma-iron levels were measured by the method of Bothwell and Mallett (1955) Plasma-^{59}Fe half-clearance times ($T^1/_2$) were determined by standard procedures (Veall and Vetter 1958) The disappearance-rate constant is given by $\frac{\text{Log}_e\ 2}{T^1/_2}$ From these data may be calculated the *plasma-iron turnover,* which was expressed as mg per 100 ml blood per day (Bothwell et al 1957)

Plasma erythropoietin activity was assayed by a technique which is to be described elsewhere (Payne 1960) Briefly this is a "four-point" bioassay using the reticulocytosis induced in rats by intraperitoneal injections of graded doses of the subject's plasma In each group of assays the test plasma is compared with pooled normal plasma Considerable experience with this technique has now been obtained, and the reproducibility and validity of its results are established

Case-reports

Case 1—A 57-year-old man was admitted to hospital in April, 1959, with left hemiplegia of sudden onset During the previous two years he had experienced "bursting" feelings in the head, particularly on stooping On examination the following findings were noted left hemiplegia, blood-pressure 210/120 mm Hg, normal optic fundi, auricular fibrillation, signs of mitral stenosis, no rise in jugular venous pressure, a large cystic mass palpable in the abdomen extending from the left loin to the suprapubic area

The urine contained 60 mg protein per 100 ml, a few leucocytes and red blood-cells, and was sterile Electrocardiography confirmed auricular fibrillation, a chest X-ray showed a slightly enlarged heart shadow, blood-urea levels varied between 40 and 48 mg per 100 ml , plasma sodium, potassium, chloride, and bicarbonate levels were within normal limits on several occasions, creatinine clearance was 85 ml per minute, intravenous pyelography showed a normal calyceal pattern in the right kidney but no excretion of dye by the left kidney, and retrograde pyelography revealed a very large left hydronephrosis

The patient appeared plethoric, and was found to have a hæmoglobin of 21 8 g per 100 ml , a packed-cell volume (P C V) of 62%, a red-blood-cell count of 6,800,000 per c mm , a white-blood-cell count of 9,900 per c mm with a normal differential cell-count, a platelet-count of 171,000 per c mm , and an erythrocyte-sedimentation rate of 1 mm in the first hour (Westergren), the highest values recorded are quoted

Examination of the sternal marrow showed slight erythroid hyperplasia The spleen was not palpable The total body-weight was 72 0 kg , the urea space 42 8 litres, and the lean body mass 58 6 kg

The diagnosis of polycythæmia was established by the finding of an increased red-cell volume (R C V) Further investigations of the polycythæmia are described under "Results" Despite the absence of cyanosis the presence of the heart lesion made it important to exclude an anoxic cause of the polycythæmia, the arterial blood-oxygen saturation was normal (95%)

On June 8, 1959, left nephrectomy was performed A huge thin-walled hydronephrotic sac containing about 6 litres of milky fluid was found, this fluid was sterile No kidney tissue could be identified macroscopically, and histological examination of the sac wall showed fibrous tissue infiltrated by chronic inflammatory cells and containing a few renal tubular elements At operation blood samples were obtained from the aorta, the left renal vein, and a peripheral arm vein at the same time These samples were assayed for erythropoietin activity, and the results are discussed later

Postoperatively the patient's recovery was uneventful Subsequent changes in hæmoglobin and hæmatocrit levels are shown in fig 1 The white-cell and platelet counts remained normal Postoperative studies of red-cell volume, iron metabolism, and erythropoietin levels are described below

Case 2—This obese 55-year-old railwayman was found to have auricular fibrillation at a routine medical examination When he was admitted to hospital no other signs of heart-disease were found, there was no evidence of cardiac failure, the blood-pressure averaged 160/90 mm Hg, the heart was not enlarged radiographically, and electrocardiography showed only auricular fibrillation He appeared to be euthyroid An unsuccessful attempt was made to bring about reversion to normal cardiac rhythm with quinidine

The patient had a plethoric complexion and was found to have a hæmoglobin of 18 8 g per 100 ml, P C V 57%, a platelet count of 185,000 per c mm , a white-blood-cell count of 13,000 per c.mm. (neutrophils 80%, lymphocytes 16%, monocytes 4%), the highest values recorded are quoted The spleen was not palpable The diagnosis of polycythæmia was confirmed by the finding of an increased red-cell volume Further studies of the polycythæmia are described below

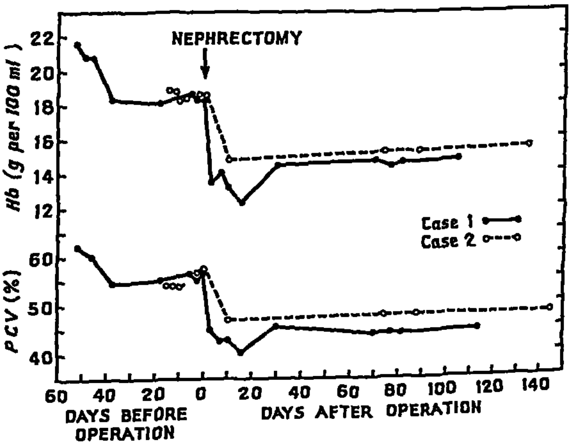

Fig 1—Hæmoglobin and hæmatocrit values before and after operation

* Bothwell et al. (1956) † Bothwell et al. (1957)

The total body-weight was 100 kg, the urea space 52·0 litres, and the lean body mass 71·3 kg.

To exclude a renal cause of the polycythæmia intravenous pyelography was performed. The left kidney appeared normal, but on the right side the upper calyceal group was much dilated, the upper pole of the kidney was enlarged, and a rounded indentation of the calyx was seen. The blood-urea was 25 mg per 100 ml. and the creatinine clearance was 75 ml per minute. The urine contained an occasional leucocyte but no protein and was repeatedly sterile, no tubercle bacilli were seen in it, and Löwenstein cultures were negative. The right kidney was explored surgically on May 2, 1959, and a large multilocular cyst was removed from the upper pole. Several smaller cysts were present in the remainder of the kidney, but this was left in situ as considerable normal tissue appeared to be present. Histological examination of the cyst showed the wall to be largely fibrous although lined in part by cuboidal epithelium. There was no evidence of malignant change.

Postoperatively the patient has remained well for six months to date, although auricular fibrillation has persisted. Three months after operation the following findings were obtained: Hb 15·1 g per 100 ml., P.C.V. 48%, platelets 270,000 per c.mm., white blood-cells 8900 per c.mm. The R.C.V. was now normal. Further studies are described below.

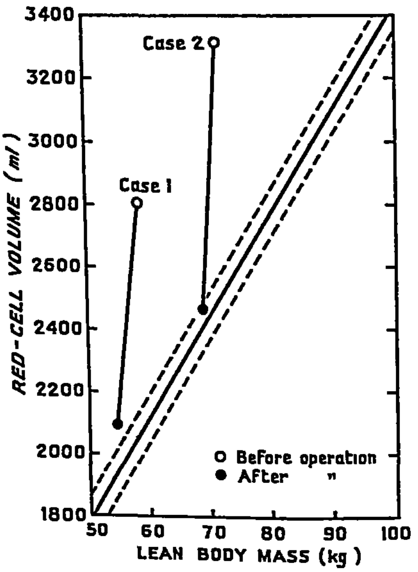

Fig. 2—Red-cell volumes before and after operation.

The solid regression line relating the normal mean red-cell volume to lean body mass is taken from the data of Muldowney (1957), ($y = 32.74x + 155.17$). The interrupted lines represent 95% confidence limits.

Results

Red-cell Volume, Hæmoglobin, and Hæmatocrit
(see table I and figs 1 and 2)

Before nephrectomy both patients had raised hæmoglobin concentrations 21·8 g and 18·8 g per 100 ml. The highest hæmatocrit values were 62% in case 1 and 57% in case 2. After operation the hæmoglobin and hæmatocrit values returned to normal (fig. 1) and have remained so.

In case 1 the red-cell volume (R.C.V.) before operation was found to be 2805 ml, whereas the upper 95% confidence limit for normal R.C.V. predicted from the lean body mass was 2145 ml. Four weeks after nephrectomy the R.C.V. was 2103 ml. Owing to weight loss the predicted upper limit of normal at this time was 2014 ml.

In case 2 the R.C.V. before nephrectomy was 3317 ml, whereas the upper limit of normal R.C.V. was 2564 ml. Eleven weeks after operation the R.C.V. was 2468 ml.

Plasma-iron Turnover (see table I)

In each case before operation the plasma-^{59}Fe half-clearance time was shortened (54 minutes and 28 minutes) while the turnover of iron through the plasma was increased (0·80 and 1·20 mg per 100 ml blood per day). Eleven weeks after nephrectomy the plasma-^{59}Fe half-clearance times had returned to normal (75 and 72 minutes) and so had the plasma-iron turnover (0·75 and 0·64 mg per 100 ml blood per day). The change in plasma-iron turnover was much greater in case 2 than in case 1.

Erythropoietin (see table II)

Before nephrectomy the plasma-erythropoietin activity was raised to 8 times normal in case 1 and 43 times normal in case 2. The erythropoietin levels eventually became normal after removal of the diseased kidney.

In case 1 blood samples were obtained at operation from the left renal vein (the side of the hydronephrosis), from a peripheral arm vein, and the aorta. The peripheral venous erythropoietin level was elevated to the same degree as in the preoperative specimens (8 times normal). The aortic and left renal venous samples, however, contained much less erythropoietin activity (twice normal).

Discussion

The essential feature of polycythæmia is an increased total red-cell volume, and Lawrence (1955) has stressed the danger of diagnosing polycythæmia on hæmoglobin concentration, hæmatocrit, or red-cell counts when these are not grossly abnormal. Even when the red-cell volume is known the significance of borderline values may be difficult to decide since the normal red-cell volume of a given subject cannot be predicted from his weight with any accuracy. Muldowney (1957) has shown that the

TABLE II—ERYTHROPOIETIN ASSAYS BEFORE AND AFTER OPERATION

* 95% confidence limits 60–160%, this implies that 95 times in 100 the true mean would lie within these limits.

fat-free body mass (lean body mass) is a much more accurate parameter for red-cell volume, and we have confirmed this relationship (Hyde and Jones 1960) The red-cell volumes in our 2 subjects were therefore related to lean body mass (see fig 2) The results show that in each case there was initially a true increase in the circulating red-cell volume Eleven weeks after nephrectomy case 2 had a normal red-cell volume Four weeks after nephrectomy case 1 had a red-cell volume which was only 90 ml above the upper limit of normal, compared with a preoperative value which exceeded this limit by 760 ml At this time the plasma-erythropoietin level had not yet returned completely to normal The operation was virtually bloodless in each case, and no other specific therapy was given

In each case reported here the plasma-iron turnover was initially increased but became normal after nephrectomy This change reflects the postoperative fall in red-cell production that may be inferred from the return to normal of the red-cell volume, hæmoglobin concentration, hæmatocrit, and plasma-erythropoietin level

Gardner and Freymann (1958) concluded from a survey of published reports that the percentage of plasma-iron removed per hour (i e, the ^{59}Fe-disappearance-rate constant × 100) was significantly greater in polycythæmia vera (209 7% ± 96 9%) than in secondary (anoxæmic) polycythæmia (79 5% ± 29 6%) In the case of polycythæmia with hydronephrosis reported by these workers the percentage of plasma-iron removed per hour was 210, thus resembling polycythæmia vera in this respect In the 2 cases we report the corresponding figures were 77% and 149%, the first being within the range cited for secondary polycythæmia while the second resembles more closely that for polycythæmia vera It does not seem likely that this parameter will prove a useful one with which to contrast primary and renal polycythæmia

The existence of one or more humoral factors (erythropoietin) controlling erythropoiesis is now widely recognised, and it has been shown that plasma-erythropoietin levels are raised in polycythæmia vera (Contopoulos et al 1957, Linman and Bethell 1957) An increasing body of experimental work suggests a close relationship between the kidney and plasma-erythropoietin (Jacobson et al 1957, Goldwasser et al 1958, Naets 1958, Osnes 1958, Lange et al 1959) The plasma-erythropoietin level is not raised in the anæmia of chronic renal failure (Lange et al 1959), whereas erythropoietin levels are elevated in most other anæmias (Piliero et al 1956, Gordon 1959) This difference has been taken as evidence that the anæmia of chronic renal failure results from inadequate production of erythropoietin by the damaged kidneys

Previous studies of renal polycythæmia have not included measurements of erythropoietin. In the present 2 cases the elevated erythropoietin levels and the subsequent fall to normal after nephrectomy further support the concept of an intimate relationship between plasma-erythropoietin and the kidney

Much of the above work suggests that in certain pathological conditions the kidneys may produce increased amounts of erythropoietin However, Hirsjarvi (1955, 1958) has reported experiments indicating a peripheral activation, or formation, of erythropoietin The finding in case 1 that the venous blood draining from the hydronephrotic kidney had a lower erythropoietin level than blood from an arm vein is further evidence of such a peripheral mechanism How some kidney lesions might affect this remains uncertain and further work is needed to clarify the relationship between the kidney and erythropoietin.

The association of polycythæmia with renal carcinoma has been reported in at least 34 cases (see Damon et al 1958 and Forssell 1958) In a series of 205 patients with polycythæmia, Damon et al (1958) found 9 cases of renal carcinoma (an incidence of 4 4%) Lawrence and Donald (1959) found that renal carcinoma occurred in 0 93% of a series of 325 polycythæmic patients, whereas the expected incidence of renal carcinoma in America is 0 003% These figures suggest that this association is not fortuitous The long remissons of the polycythæmia that have followed successful nephrectomy is further evidence for this conclusion

Coexistent polycythæmia and non-neoplastic renal disease have been reported to date in 10 cases (see table III) The numbers of any one type of renal lesion are as yet too small to exclude a chance association, and the true prevalence of kidney disease associated with polycythæmia remains unknown Increasing awareness of this syndrome may well lead to more frequent recognition It is interesting that in 3 of the 6 cases with polycystic kidneys this condition was unilateral

In addition to the 2 cases reported here the results of nephrectomy in polycythæmia associated with non-neoplastic renal lesions are available in 4 other patients, and in each case remission of the polycythæmia has occurred In 3 of these cases (including both our patients) no other specific therapy was given These facts are further evidence of a causal relationship between certain renal lesions and polycythæmia

In polycythæmia vera increased white-cell and platelet counts are common, while the spleen is usually palpable at some stage of the disease Damon et al (1958) concluded that most patients with polycythæmia and renal carcinoma lack splenomegaly, leucocytosis, and thrombocytosis, so that the " polycythæmia " is more properly termed " erythrocytosis " The data in table III suggest that in polycythæmia associated with non-neoplastic renal lesions the spleen is usually impalpable and the platelet count usually normal White-cell counts greater than 10,000 per c mm were obtained in 6 of the 10 cases, but the figures cited are the highest obtained in each case and all may be within normal limits The results of bone-marrow examination are available in 7 of the 10 cases, and, whereas increased erythropoiesis was noted in 5 cases, no mention is made of excessive myeloid activity The available data are insufficient to decide whether hypertension is more common in renal polycythæmia than in polycythæmia vera In summary, renal polycythæmia is usually characterised by an erythrocytosis with normal platelet and white-cell counts while the spleen is impalpable

Certain practical implications follow from the recognition of this syndrome of renal polycythæmia The possibility of an underlying renal lesion should be considered in any polycythæmic patient, especially when white-cell and platelet counts are normal, and the spleen cannot be felt Examination of the urine, palpation of the loins, and intravenous pyelography should be undertaken in such a case Hæmaturia has sometimes been attributed to an abnormal bleeding tendency in polycythæmia Hæmaturia occurred, however, in most of the reported cases of polycythæmia with renal disease, and its occurrence should intensify the search for a renal lesion Because the polycythæmia may remit after nephrectomy, diagnosis of the kidney disease in renal polycythæmia is especially important

Summary

In 2 cases of polycythæmia—1 associated with hydronephrosis and the other with a unilateral polycystic kidney—the polycythæmia disappeared after removal of the renal lesions

Plasma-erythropoietin levels were raised before operation but fell to normal after nephrectomy

Plasma-iron turnover was initially increased but returned to normal after nephrectomy

The features of this type of polycythæmia and the part played by the kidney in the control of erythropoiesis are discussed

The syndrome of renal polycythæmia is probably commoner than is realised Diagnosis of the renal lesion is important because its removal may lead to remission of the polycythæmia

We wish to thank Dr G Wetherley-Mein and Dr Brian Creamer for much useful advice, Prof F T G Prunty and Dr J L Pinniger, for encouragement and permission to investigate these patients in the William Dunn and Louis Jenner Laboratories, and Dr R Daley and Dr Evan Jones, who allowed us to study and to report their patients

Bispebjerg Hospital, Copenhagen

As early as 1950, Spuler and Zollinger in Switzerland drew attention to a chronic interstitial nephritis which they suggested was due to prolonged abuse of phenacetin-containing analgesics, since a very great proportion of their patients had been addicted to these preparations (Spuler and Zollinger 1953)

In attempts to reproduce the syndrome by animal experiments and to determine the significance of phenacetin, Studer and Zbinden (1955) demonstrated slight degeneration of the tubules but no genuine interstitial nephritis in rats given large doses of ' Saridone ' for long periods On the other hand, Thölen et al (1956) were able to produce interstitial nephritis in corresponding experiments in mice, possibly because in these animals spontaneous urinary infection with *Clostiela muris* is common Moreover, Miescher et al (1958) produced interstitial nephritis in rabbits by feeding them with phenacetin and simultaneously giving *Escherichia coli* intravenously (injection of *Esch coli* in a control group did not produce renal injury)

Direct provocation experiments are probably necessary to demonstrate the relation of phenacetin to chronic interstitial nephritis in man In a series of patients who had abused phenacetin and whose renal function was reduced, we therefore undertook direct provocation experiments with pure phenacetin and with phenacetin contaminated with acetic-4-chloranilide (preparations of phenacetin usually contain this contaminant) Quantitative changes in the urinary sediment were used as a measure of renal irritation

Effects of Provocation

11 patients were given phenacetin entirely free from acetic-4-chloranilide, 8 patients had phenacetin containing 0 13% acetic-4-chloranilide, and 8 phenacetin containing 0 30% acetic-4-chloranilide For three days, all drugs were withdrawn and then the patients received 3 g daily of the phenacetin preparation for five days Both in the preliminary period and the five days of the experiment, sediment counting by

the Addis method was undertaken daily on a twelve-hour sample of night urine to which toluol was added as preservative The urinary sediments were counted immediately after collection of urine, and all counts were undertaken by one laboratory worker, experienced in the technique In the analysis, only the erythrocyte and leucocyte values were considered

The erythrocyte and leucocyte counts recorded are shown in tables I and II

Probably because of the inexactitude of the counting method, the scatter of the twenty-four-hour values is great, so that the considerable variations from day to day make it hard to see directly whether the sediment values are higher than usual during provocation with phenacetin in individual patients It proved suitable in the statistical analysis to use logarithmic values for the urinary sediments since the standard deviation of the logarithms, by and large, seemed to be independent of the absolute quantity of the urinary sediment in the individual patients For each of the preparations of phenacetin the average logarithm of the sediment values in the preliminary period was compared with the corresponding value in the treatment period The results of the statistical analysis were shown in table III

A significant increase in the erythrocyte-count in the urinary sediment was found during treatment with both of the preparations containing acetic-4-chloranilide, on the other hand, a significant increase in the leucocyte-count was recorded only in the experiment in which phenacetin with 0 13% acetic-4-chloranilide was used With pure phenacetin the increase in the erythrocyte-count was approximately 15% and in the leucocyte-count approximately 11%, but these differences were not significant

Discussion

The results support the view that phenacetin-containing preparations may damage the kidney Preparations containing acetic-4-chloranilide may be chiefly responsible, since the quantitative change in the urinary sediment is much more pronounced with them than with purified phenacetin The observation that the effect of the most markedly contaminated preparation was less than that of a purer preparation may be explained by the fact that the patients in the last series had better renal function than those in the first two series The degree of renal irritation may partly depend on the patients' renal function, being greatest when function is poor

As Hald (1950) showed, the preparations of phenacetin at present available contain varying quantities of acetic-4-chloranilide as a contaminant Analysis of 22 preparations of phenacetin revealed contamination varying from 0 02 to 0 64% The *Danish Pharmacopœia*, which, with the exception of the *British Pharmacopœia*, is the only one to give directions on this subject, permits a maximum of 0 35% acetic-4-chloranilide Acetic-4-chloranilide is a much more potent former of methæmoglobin than phenacetin (Gad *et al* 1950), and the question arises whether abnormal hæmoglobin products may be responsible for the renal damage

Phenacetin was originally manufactured by synthesis from 4-nitrophenol, and contamination with acetic-4-chloranilide did not occur For twenty or twenty-four

TABLE III—COMPARISON BETWEEN URINE COUNTS BEFORE AND DURING TREATMENT WITH PHENACETIN

—	Mean of logarithms of absolute urine counts		Difference	t-value

years, however, phenacetin has been prepared from 4-nitrochlorbenzol, with acetic-4-chloranilide as a by-product This change may explain why the toxic action of phenacetin-containing preparations was detected only in recent years

Summary

In recent years suspicion has arisen that chronic abuse of phenacetin and phenacetin-containing analgesics may cause severe renal damage The nephrotoxic effect of phenacetin was estimated in 27 addicts by quantitative determination of the urinary sediment by the Addis method

In 11 patients given purified phenacetin, a slight but not significant rise was registered, in 16 patients given phenacetin contaminated with acetic-4-chloranilide (a contaminant found in varying amounts in practically all preparations of phenacetin) the effect was much more pronounced, with significant rise in both erythrocyte and leucocyte counts As acetic-4-chloranilide is a much stronger former of methæmoglobin than phenacetin, renal damage may be caused by the abnormal hæmoglobins, and not by a direct toxic effect of phenacetin or related drugs

We wish to express our gratitude to Dr Jens Hald, of Meco-Dumex Ltd (former Medicinalco Ltd), for the interest taken in our work and for the suggestion that we examine the effect of acetic-4-chloranilide-containing drugs We also wish to thank Miss Inger Ladegård for technical assistance The work was supported by a grant from King Christian X's Fund

SPEED OF ACTION OF ASPIRIN, SOLUBLE ASPIRIN, AND BUFFERED ASPIRIN

PETER SLEIGHT
M B Cantab , M R C P
MEDICAL FIRST ASSISTANT, ST GEORGE'S HOSPITAL, LONDON, S W 1

ASPIRIN (acetylsalicylic acid) is probably the most widely prescribed drug in this country In 1954 3000 million tablets of aspirin were produced in the United Kingdom Recently various proprietary brands of acetylsalicylic acid have been recommended as having a faster action or fewer side-effects, but there seems to be no conclusive evidence in favour of these claims

Aspirin is absorbed from the stomach of dogs with the pylorus ligated, but it is absorbed most quickly from the intestine (P K Smith 1949) Any factor which influences gastric emptying may therefore be expected to influence aspirin absorption correspondingly Bradley et al (1936) showed that aspirin itself caused an increase in gastric secretion and delay in gastric emptying, but whether it acts locally or by way of a central stimulus of gastric secretion is unknown (*British Medical Journal* 1952)

M J H Smith (1951) gave 6 subjects aspirin *B P* and a proprietary aspirin, and found higher serum levels with the proprietary preparation Paul et al (1950) similarly compared a buffered aspirin with aspirin *U S P* and concluded that the buffered aspirin gave serum levels twice as high at 10 and 20 minutes after administration, but in their trial the two drugs were not compared in the same subjects More recently Cronk (1958) and Batterman (1958) compared buffered aspirin with a rapidly disintegrating non-buffered aspirin and found no significant differences after gr 10 doses in cross-over trials involving 9 and 20 subjects No mention is made of the method of administration of the tablets except that they were given by mouth

The present study concerns the speed of absorption of aspirin in normal subjects free from gastrointestinal disease, under strictly controlled conditions Each subject was given aspirin *B P*, soluble aspirin *B P* (calcium aspirin), and two proprietary preparations—namely, acetylsalicylic acid plus aluminium carbonate and magnesium carbonate in small amounts ('Bufferin'), and acetylsalicylic acid plus glycine ('Paynocil')

Methods and Materials

There are several established methods for the estimation of plasma salicylate, the best-known being that of Brodie et al (1944) These, however, were developed mainly for measuring the high values occurring during the treatment of acute rheumatism, and were not easily applicable to the low serum levels of this trial Also, they involved the use of the toxic substance ethylene dichloride M J H Smith (1951) described a method for this type of study and this has proved satisfactory in my hands It was used unmodified except that the instrument used was a Cambridge 'Unicam' S P 600 with the red cell transmitting at 750 μ For serum levels below 10 mg per 100 ml the variation due to the method was less than 0 5 mg per 100 ml

Six healthy volunteers (aged 20–33) who had not taken any salicylate in the previous 72 hours were given gr 10 doses of aspirin in the four forms, using a double-blind technique The tablets, aspirin *B P*, calcium aspirin *B P*, paynocil, and bufferin were obtained and prepared by the hospital pharmacist and labelled A, B, C, and D, their identity was not revealed to the investigator until the statistical analysis had been made The tablets were given in predetermined random order using the method of roman squares—i e , the six subjects received the tablets A, B, C, and D in a different order This ensured that a given tablet was not always administered first or last and that on any particular day the tablets were being estimated side by side, eliminating as far as possible any bias due to variation in experimental conditions

The tablets were given under standard conditions 2 hours after the subject's normal breakfast. As stated previously, earlier trials have given little information on the method of administering tablets If swallowed whole, a tablet which is slow to disintegrate is likely to be at a disadvantage compared with one which disintegrates rapidly To avoid this discrepancy the tablets were crushed in 2 oz of water and the glass was then rinsed twice in 2 oz of water so that the dose was taken in a total of 6 oz of water The tablets differed considerably in the ease with which they were dispersed

Blood was drawn by repeated venepuncture at 0, 10, 20, and 30 minutes, the time recorded being the moment of venous occlusion Each time 15 ml of blood was withdrawn smoothly by dry syringe into a heparinised bottle containing added fluoride A pilot survey had shown that heparin caused no hæmolysis When oxalate or citrate was used hæmolysis was only slight, but it proved troublesome because it led to high "blank" values in the zero-time specimens

The collected specimens were then centrifuged and the serum-salicylate values estimated as mg sodium salicylate per 100 ml , almost exactly convertible into mg acetylsalicylic acid (molecular weight sodium salicylate = 173, acetylsalicylic acid = 180)

TABLE I—MEAN TOTAL SALICYLATE LEVELS (EXPRESSED AS MG SODIUM SALICYLATE PER 100 ML)

30 minutes	5 4±1 03 (4 5–6 8) 4	5 3±1 35 (2 8–6 6) 6	4 6±1 57 (2 8–6 8) 6	3 3±1 09 (1 5–4 5) 6

Range in parentheses Number of observations below

Normal serum containing no salicylate gives a faint blue colour as compared with the reagent blank and this reading at zero time (varying with each patient but usually equivalent to about 0 5 mg acetylsalicylic acid, or less, per ml) was deducted from the readings obtained at the specified times to obtain the true salicylate levels at those times

Calibration curves were done repeatedly during the period of the trial and did not appear to differ significantly However, with each test a freshly prepared standard solution of 5 mg aspirin per 100 ml was run through in addition to the plasma and reagent blanks Occasional values are missing—e g , because of failed venepuncture, insufficient plasma, or obvious hæmolysis in one specimen of a batch, but in the statistical analysis these values have been taken into consideration

The levels of serum acetylsalicylic acid are obtained from the differences between aliquots of serum at each time, one aliquot is estimated for free salicylate, the other for total salicylate after hydrolysis by caustic soda

At the conclusion of the experiment random samples were taken from each of the original batches or tablets and analysed for total salicylate content The variation in content between tablets in the same batch was of the order of five per cent and there was no consistent difference between the aspirin content of the different groups

All venepunctures and all salicylate determinations were done by myself, thereby ensuring standard technique at all stages

Results

Results are shown in tables I and II The scatter between the values for each subject (figures in parentheses) mainly represents individual variation in the subjects themselves, since the variation due to the method was found to be usually less than 0 5 mg per 100 ml

Serum salicylate levels were much the same (table I) after taking bufferin, soluble aspirin *B P*, and paynocil, but considerably lower after taking aspirin *B P* The difference was significant at the 1% level at all times if aspirin is compared with the other three groups combined (see figure)

Plasma levels for acetylsalicylic acid differ little for the four aspirin preparations given (table II) The fact that they are all relatively low might be explained by partial failure of the fluoride present in the anticoagulant to inhibit the serum esterase concerned Lester et al (1946) found that an average of 25% of the total salicylate was present as acetylsalicylic acid The proportion found here varied from 10–25% approximately

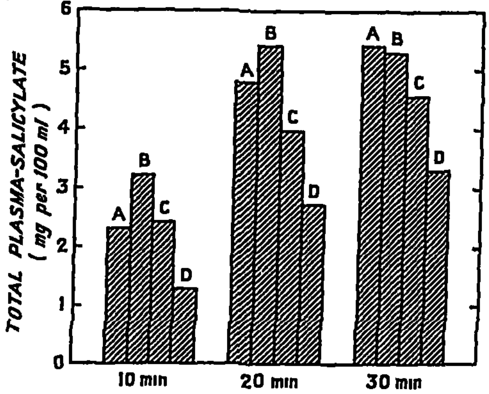
Discussion

Judging by evidence from blood-levels, plain aspirin has been shown to be roughly half as rapidly effective as soluble aspirin This difference might be expected from its known insolubility However, both paynocil and bufferin show a similar superiority and contain plain, not soluble, aspirin Possible explanations include the method of administration of the tablets, the particle size of the aspirin in the tablets, and speedier gastric emptying

Since aspirin itself will delay gastric emptying, it may be that the two proprietary preparations are less irritant and emptying is speedier than in the case of aspirin *B P* It seemed likely that there might be a loose combination between aspirin (a weak acid) and glycine (a weak base) in paynocil, since in this preparation it is not possible to distinguish the characteristic taste of aspirin on the tongue, but chromatographic analysis of solutions of these two components gave no support for this theory In the case of bufferin the present results confirm those of Paul et al (1950) and are at variance with those of Cronk (1958) and Batterman (1958) who found no difference between bufferin and a rapidly disintegrating proprietary aspirin



Total plasma-salicylate levels at intervals after 10-grain doses of aspirin by mouth A = bufferin, B = soluble aspirin *B P*, C = paynocil, D = aspirin *B P*

The presence of acetylsalicylic acid in the serum has been demonstrated again (Lester et al 1946, Smith 1951, Mandel et al 1954) Normally, significant quantities of the drug remain only for two to three hours (Gross and Greenberg 1948), because of its rapid hydrolysis to sodium salicylate by serum esterase The fact that aspirin is more diffusible than plain salicylate, because less of the former is protein-bound in the serum, probably explains the therapeutic superiority of aspirin over plain salicylate The clinical corollary of this is that, if aspirin is to be used logically it should not be said to be ineffective unless it has been taken at short intervals (i e , two- or three-hourly) This is particularly important in the relief of long-continued pain as in rheumatoid arthritis

The present trial demonstrates that under standard conditions calcium aspirin *B P* was as effective in giving rapid blood-levels as two proprietary buffered aspirins (paynocil and bufferin) but that all three were superior to plain aspirin *B P* The relative costs to the hospital service of these three drugs are

Aspirin *B P* = 0 12*d* for 10 grains aspirin
Soluble aspirin *B P* = 0 22*d* „ „ „ „
Buffered aspirin (paynocil) = 0 54*d* „ „ „ „
„ „ (bufferin) = 1 1*d* „ „ „ „

The superiority of calcium aspirin over plain aspirin in the rapid achievement of demonstrable blood-levels is stressed If in addition account is taken of the evidence incriminating plain aspirin as a cause of serious side-effects such as gastrointestinal hæmorrhage (Muir and Cossar 1955), its continued use appears questionable

Summary

Blood-levels of acetylsalicylic acid and salicylate obtained at 10, 20, and 30 minutes after gr 10 doses of aspirin *B.P*, soluble aspirin *B.P*, and two buffered preparations paynocil and bufferin were compared

Soluble aspirin *B.P* gave approximately twice the blood-levels of aspirin *B.P* at these times and equal levels were obtained with paynocil and bufferin, both of which were similarly superior to plain aspirin *B P* Suggested explanations are diminished local irritation and consequent speedier gastric emptying when soluble or buffered aspirins are used

The presence of unchanged acetylsalicylic acid is again demonstrated in serum and the significance of this discussed, with particular reference to the point that aspirin therapy cannot be said to have failed unless the drug has been taken at two- or three-hourly intervals

I am grateful to Dr Kenneth Robson, who originally suggested the study, and to Dr J C. Batten, for advice and encouragement, to Prof. J Knowelden for help with the statistical planning of the trial, and to Mr G Franglen for carrying out the chromatography and assisting with the statistical calculation.

I wish to acknowledge a grant from the research committee of St. George's Hospital towards expenses

SENIOR PHYSICIAN IN DISEASES OF THE SKIN,
KING'S COLLEGE HOSPITAL

Knedel (1957, 1958) reported an abnormal protein in the serum of a 15-year-old girl with hepatitis Her sister, her mother, her maternal grandmother, and a maternal uncle all had a similar anomaly The sera from two cousins (a daughter and son of the uncle) did not contain demonstrable amounts of the anomalous protein From its electrophoretic and immunological behaviour, Knedel thought the protein was an albumin. Other families with a similar anomaly have been reported by Nennsteil and Becht (1957), Wuhrmann (1958), Bennhold, Ott, and Scheurlen (1958) and Earle, Hutt, Schmid, and Gitlin (1958, 1959)

Case-report

A boy of 16 was seen in the skin department of King's College Hospital last August, with a curious condition of the hands These had always been cold and blue even in summer In the previous three years there had been an increasing flexural deformity of the fingers—first of the little fingers, and later, to a lesser degree, the ring, middle, and index fingers of one hand. It was difficult to account for his inability to straighten these fingers there was no sclerosis of the skin, nor, apparently, any involvement of fascia or tendons The horny layer over the knuckles was slightly thickened and a slight mosaic of hyperkeratosis could be seen in the nailfolds The condition was clearly not acrosclerosis nor any form of Raynaud's phenomenon The boy's father had similar hands but could straighten his fingers normally The paternal grandfather (deceased) was said to have had cold blue hands

Investigations

In the course of various laboratory investigations paper-electrophoretic analysis of the serum proteins revealed, in both father and son, a distinct double band in the region of the albumin. The sera were submitted to an independent laboratory for confirmation and further study There, among other investigations, electrophoresis was carried out on filterpaper and in agar against known albumin controls and by the classical moving boundary method of electrophoresis The presence of a second component in the region of the albumin was confirmed (fig 1) Sera from the other members of the family were collected and examined. As in the family reported from America, the genetic pattern (fig 2) seems to be that of a dominant heterozygote.

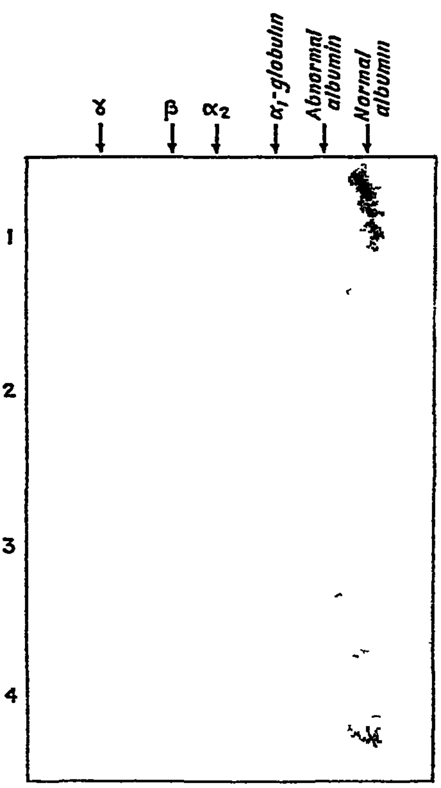

Fig 1—Electrophoretic demonstration of second component in region of albumin

We have assumed that the faster of the two " albumin " components is that normally seen in electrophoretic analysis We believe that the second peak represents an albumin, for the following reasons

1 (*a*) Zone electrophoresis on paper, cellulose acetate, and agar all displayed a well-defined double band having a mobility similar to that of albumin and faster than that

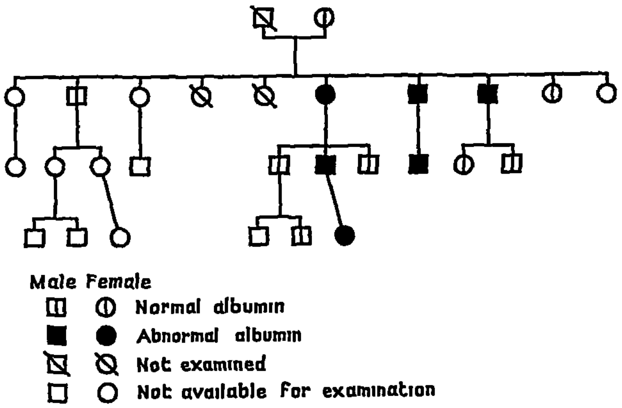

Fig 2—Pattern of inheritance

of the α_1-globulin in the control normal serum Moreover α_1-globulin could be identified, clearly separated from the abnormal " albumin ", having a mobility similar to the α_1-globulin in the control serum.

(*b*) When the serum proteins were subjected to moving-boundary analysis in 0 2 *M* phosphate buffer at pH 8 0 for six hours, a well-defined " hump " was seen on the posterior slope of the albumin peak, the α-globulin being clearly discernible behind it (fig 3) The " hump " was constant on prolonged electrophoresis, its mobility being within the range of normal albumin

2 When the serum proteins were exposed in buffered aqueous solution to *n*-tolyl-α-naphthylamine-8-sulphonic acid, a dye believed to couple specifically with albumin (Weber and Lawrence 1954), electrophoretic analysis showed that both " albumin " bands had coupled with the dye and that none of the other serum proteins present produced a fluorescent-coupled compound in this manner Moreover the behaviour of the abnormal component with sulphonphthalein dyes also paralleled that of normal albumin (Franglen 1958)

3 The two components were separated by electrophoresis on starch block (Kunkel and Trautman 1959) Comparison of the two components by immunological techniques showed no difference between the two " albumins " nor between them and normal human albumin (fig 4)

Discussion

This is the first family to be described in this country displaying this unusual serum-protein anomaly—the eighth, so far as we can ascertain, in the world literature In none of the other families has the anomaly been shown to be associated regularly with any other demonstrable defect, most of the members being in perfectly good health

In the present family the peculiar dermatological condition was noted in father and son There is evidence that the grandfather also suffered from " cold blue hands " As we could not demonstrate the split albumin in the grandmother, it is reasonable to suppose that this defect was transmitted through the grandfather While it is tempting to link the unusual skin condition with the protein abnormality, we must admit that four other members (two female and two male) showing the split albumin had no dermatological defect

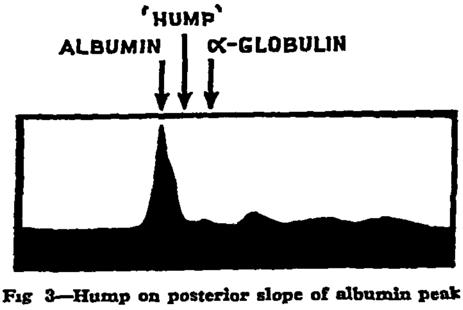

Fig 3—Hump on posterior slope of albumin peak

Preliminary studies have shown no striking deviations in the aminoacid analysis of the abnormal albumin If we assume that the shape and size of this component does not differ markedly from normal albumin, the electrophoretic analyses suggest that the net surface charge of the molecule is very near to that of normal albumin

Bergstrand and Czar (1956, 1957) described a protein migrating between albumin and α_1-globulin in the serum from fœtuses up to the 19th week, obtained from legal abortions They reported this component to be about 10% of the normal albumin present Such quantitative studies as we have made suggest that the abnormal albumin which we are now describing represents about 50% of the total albumin and that this proportion is remarkably constant—a finding similar to that of Earle et al (1959) In thalassæmia (another hereditary protein dyscrasia) the fœtal type of hæmoglobin persists in varying amounts in different members of the family Though it is tempting to propose that our abnormal albumin represents a persistence of the fœtal component described by Bergstrand and Czar, the condition differs from thalassæmia in one striking respect — namely, that all the members of the family we have examined, extending through four generations, have shown the component at a level of 50% of the total serum-albumin or else none at all

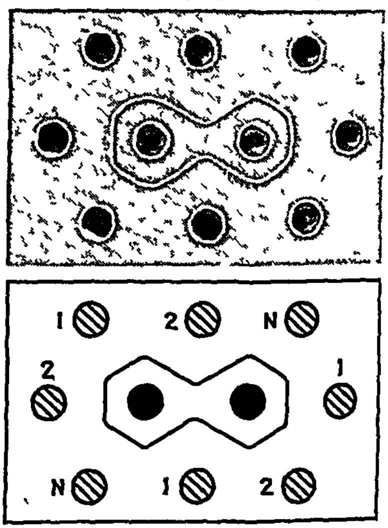

Fig 4—Comparison of two "albumins" and normal human albumin

Summary

In a family followed through four generations a bifid albumin occurs as a dominant heterozygous character Reasons are given for regarding the abnormal component as albumin, and a comparison is drawn with thalassæmia

In three successive generations an unusual skin condition was observed in three of the seven members of a family believed to be suffering from the protein dyscrasia

THE THORN IN THE FLESH

A J Buhr*
B.A , M D Univ Western Ontario
From The Accident Service, The Radcliffe Infirmary, Oxford

In 1787, two years after publishing An Account of the Fox-Glove and Some of its Medical Uses, William Withering, writing about *Prunus spinosa* (blackthorn or sloe-tree) noted that " the thorns have something of a poisonous nature in the autumn " In 1801 he confirmed this observation " From some effects which I have repeatedly observed to follow the prick of the thorns, I have reason to believe there is something poisonous in them "

I have recently observed and treated ten patients with this injury No other similar series has been reported in English.

Most of the patients were agricultural workers, and, as might be expected, all the injuries were in the hand There was no particular seasonal incidence

The average interval between time of injury and first visit to the accident service was 8 7 days, and the average duration of outpatient treatment was 45 days By comparison, 60 patients with other thorn injuries—e g , rose, hawthorn, gooseberry, &c , or unspecified—were treated as out-patients for an average of 11 9 days

Illustrative Case

A 67-year-old thatcher injured his left index finger with a blackthorn at the end of January, 1958 Next day " the finger started swelling and throbbing," and on the day after that his doctor started him on a week's course of tetracycline At the end of the week he was able to resume work, but 2 days later his symptoms recurred and he was given intramuscular penicillin one mega-unit daily for 7 days " The finger settled and the swelling went down ", but symptoms returned when he had been back at work for 2 days

After a sleepless night he was first seen by us on Feb 13 He did not look ill and was apyrexial His left index finger showed minor occupational scarifications in addition to the blackthorn puncture wound on the flexor aspect of the proximal interphalangeal joint. Swelling and tenderness were greatest over the proximal flexor pulp, there was no lymphangitis or lymphadenitis

Under general anæsthesia the proximal pulp space was explored. The flexor tendon sheath proved to be thickened and tense The sheath was opened, its thin yellow contents were evacuated, together with some " melon-seed bodies ", and the granulomatous material associated with the thickened tendon sheath was excised. Skin sutures were inserted and the finger splinted with a plaster slab

The contents of the tendon sheath showed many pus cells and occasional gram-positive cocci No acid-fast bacilli were seen (Ziehl-Nielsen) Culture gave a light growth of micrococci and diphtheroids but no tubercle bacilli The granulomatous material was described as " vascular granulation tissue with a dense polymorphonuclear exudate "

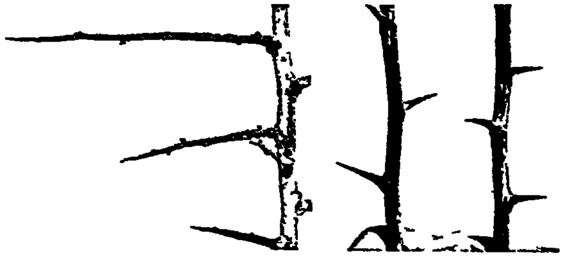
The patient was not ready to start mobilising the finger until March 4. By May 15 he could bring the index fingertip to within a centimetre of the base of the thenar eminence, and he was encouraged to return to work. He improved further during the next 10 weeks and was discharged.

This case is fairly typical Some of our other patients, with more superficial injuries, required a shorter course of treatment, especially if referred to us early The swabs revealed penicillin-resistant *Staphylococcus aureus* in three patients and penicillin-sensitive *Staph aureus* in two, no other pathogen was isolated One of our patients did not get antitetanus prophylaxis and developed tetanus of moderate severity This might have happened after any penetrating wound sustained on a farm None of the ten patients showed signs of bone infection or " bone tumour "

The patient described in the case-report twice collected blackthorns for us and delivered them in a sterile package, he obtained the specimens from the place where he sustained his injury These thorns were cultured The first specimen yielded an aspergillus, but saprophytic mycobacteria or actinomyces were not isolated Subcultures of the second specimen yielded only aerobic spore-bearers and micrococci at 22°C and 37°C

Discussion

Cactus spines, being organic material, can produce a foreign-body granuloma which may require surgical attention (Boyd 1956) Maylan (1952) recorded that certain plant thorns—e g , rose and yucca—" in or near bone can cause a reaction in this tissue which may simulate a neoplasm or granuloma " Uteau and Bouget (1928) reported that in the Basque country the peasants attribute peculiarly noxious effects to the prick of the thorns of certain shrubs These authors noted that two acquaintances had tetanus after thorn wounds Also they held that the fly-infested putrefying bodies of birds and small animals spitted on these thorns by shrikes and other birds stocking their larders accounted for the inflammation after the thorn pricks They compared these infections to those following an " anatomical prick " in the post-mortem room or the serious finger infections endemic among the cod-fishers of Newfoundland (Presumably they were referring to " fat finger " or " seal finger ", a condition well described by Candolin [1953]) Dr G Taylor, director of the Royal Botanic Gardens at Kew, told me that a member of his staff had noted that " shrikes often impale their ' kills ' on the thorns of blackthorn and that this might conceivably cause some sort of bacterial infection " Brimble (1949) pointed out that " these thorns easily snap at their tips, which explains why in some rural areas the blackthorn is supposed to be poisonous, because when the thorn penetrates the skin the tip breaks off and becomes embedded in the flesh and festering ensues " Some of the differences between the thorns of the blackthorn and hawthorn are apparent in the figure



The smooth short needle-sharp spine of the hawthorn (right) is in sharp contrast to the rough long brittle thorn of the blackthorn (left)

We inquired of Dr J W Fairbairn, reader and head of the department of pharmacognosy, University of London, and Dr W O James, F R S , professor of botany, Imperial College, London, regarding the " poisonous nature " of these thorns, but neither was aware of any toxic substance that had been isolated from them

---

* This work was done while the author had a research grant from the Nuffield Provincial Hospital Trust Present address Orthopædic Division, Toronto General Hospital, Toronto, Canada

Summary and Conclusions

1 In ten blackthorn injuries of the hand the average interval between time of injury and reference to the accident service was 8 7 days, and the average duration of outpatient treatment was 45 days

2 Sixty other patients with various thorn injuries seen during the same period required outpatient treatment for an average of 12 days

3 Bacteriological examination of these blackthorn wounds revealed penicillin-resistant staphylococci in three patients and penicillin-sensitive staphylococci in two, no other pathogens were isolated One patient developed tetanus of moderate severity Cultures of blackthorns obtained from hedges yielded no specific pathogen Histological examination showed a non-specific granulomatous reaction

I am grateful to Mr J C Scott, director of the accident service, for his interest and help, to the members of the bacteriology department and in particular to Dr R L Vollum, bacteriologist to the United Oxford Hospitals, to Dr R H Cowdell, pathologist to the United Oxford Hospitals, to Mr B Juniper, of the School of Botany, University of Oxford, and to Mr E Tugwell of the photographic department, Radcliffe Infirmary

BRISTOL ROYAL INFIRMARY AND SOUTHMEAD GENERAL HOSPITAL, BRISTOL

IN a previous investigation of postoperative urinary infection, it was found that about a third of the patients who came for operations on prostate or bladder were already infected (Miller et al 1958) Most of these infected cases had been catheterised immediately after emergency admission with acute retention of urine Many of the organisms were resistant to antibiotics, which indicated that they originated in the hospital and that in all probability the patients had acquired the infection as a result of catheter drainage, having entered the hospital with sterile urine Air bubbles which ascended in the drainage tube were found to carry bacteria to the bladder and to constitute an important cause of infection

In the same investigation, it was shown that the use of closed aseptic bladder drainage reduced infection after prostate operations, and so it seemed obvious that the same principle could be applied to bladder drainage in cases of acute retention of urine In such patients, bleeding is ordinarily no problem so that no provision is needed for washing out the bladder

Methods

In 1957 a simple closed-drainage apparatus was introduced which could be sterilised and kept ready for use in the wards It was then used in a controlled trial on patients with acute retention of urine who were admitted as emergencies to the Bristol Royal Infirmary from February, 1958, to April, 1959, and to Southmead Hospital from October, 1958, to April, 1959 Altogether, 118 patients with acute retention were treated by continuous bladder drainage, 100 had sterile urine initially and these were the subjects of our investigation Most of them came to operation after periods of drainage varying from one day to several weeks, but a few were discharged without operation For practical reasons a completely random choice of admissions could not be made, so patients admitted under the care of some surgeons were catheterised and connected to an open-drainage system, while the remainder had the special closed-drainage system connected

For open drainage, a piece of boiled rubber tubing three feet long was attached by a sterile glass connection to the catheter with the free end hanging over the side of the bed into an open bucket or urine bottle The closed-drainage apparatus (fig 1) consisted of a Winchester bottle (2-litre capacity) through the rubber stopper of which two holes were bored A glass tube through one hole dipped below the surface of 100 ml of liq formaldehyde *B P C* in the bottom of the bottle The other hole was left as an air outlet The glass tube with the rubber stopper was boiled for three minutes before assembling the apparatus The formalin served not only to sterilise the inside of the clean bottle by the overnight action of its vapour, but also as a disinfectant air trap to prevent any bacteria which might enter through the air outlet from reaching the drainage tube alive, and also to prevent the passage of air bubbles up the tube A tablet of paraformaldehyde (' Formagene ') was placed on the top of the stopper, which was then covered with a ' Cellophane ' bag to maintain the sterility of the upper end of the tube prior to use For fluid-balance records, a printed volume scale was attached to the outside of the bottle For use the cellophane bag was removed and, with aseptic precautions, the catheter was connected to the glass inlet tube of the bottle by means of a boiled rubber tube When a bottle became full, it was replaced, with careful asepsis, which included clamping the tube near its lower end to prevent the ascent of air bubbles Urine was taken for examination when the catheter was first inserted, and afterwards daily by means of a sterile needle inserted into the tube, as previously described.

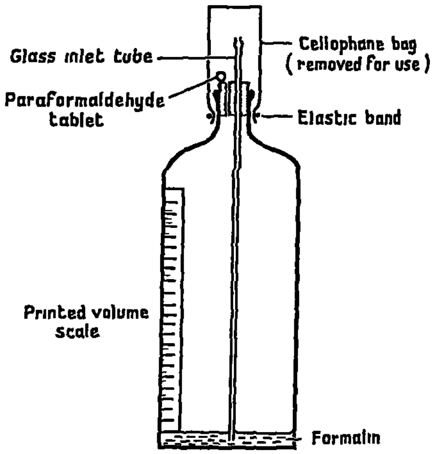

Fig 1—Apparatus for closed aseptic drainage of the bladder, when irrigation is not required

The bacteriological methods and the diagnostic criteria of infection were the same as before

Results

Of the 100 patients admitted with sterile urine, 15 were excluded from the trial for the following reasons (*a*) 7 either had an operation performed or died within twenty-four hours of admission, (*b*) 4 had prophylactic antibiotics, or (*c*) 4 required repeated catheterisation during the first few days (and all became grossly infected during this time)

Of the remaining 85 patients, 26 were treated with open drainage and 49 with closed drainage, while in a further 10 who started with closed drainage asepsis was broken by the

TABLE I—INCIDENCE OF URINARY INFECTION IN PATIENTS WITH ACUTE RETENTION OF URINE, TREATED BY OPEN BLADDER DRAINAGE AND BY CLOSED ASEPTIC DRAINAGE

Drainage	Patients	
	Total	Infected
Open	26	19 (73%)
Closed	49	5 (10%)*
Closed but disconnected	10	9 (90%)

* 2 of these patients became infected within eighteen hours of inserting the catheter, probably as a result of the catheterisation and not of subsequent retrograde infection.

disconnection of the drainage tube which was then temporarily blocked by a wooden spigot for such reasons as visits to X-ray department, bathing, and getting up to sit in a chair The nursing staff did not appreciate at first that the closed-drainage system, once established, must never be disconnected, but since the startling incidence of infection in these cases has been observed there has been no difficulty in maintaining the closed system Table I shows the incidence of infection, by organisms other than *Staphylococcus albus*, during continuous drainage in this group of 85 patients The high infection-rate (9 out of 10) in patients who had their closed-drainage system disconnected is notable and emphasises the danger of acquiring infection from spigots, blankets, pyjamas, &c

Time of Onset of Infection
